Throughout Kylin's book, useful keys are provided, first to the orders, then within orders to families, and within families to genera. In contrast to the list of diagnostic characters of the various orders, some of which are surprisingly brief, for example, those of the Cryptonemiales and Gigartinales, the general introductory sections for each family are extensive, and will be of great value for reference. After a statement of the main diagnostic characters, each of these sections contains accounts of the vegetative and reproductive organs. In the main, these are taken from "Anatomie der Rhodophyceen". The generic descriptions contain the essential information and indicate the approximate number of species with their geographical distribution. It is stated (p. 33) that 558 genera (some of which are new) and 3,740 species are mentioned. Many genera contain a small number of species, and of the fifty-five families listed at least six contain a single genus each with a single species.

* Morphological Studies on the Kallymeniaceae, by R. H. Norris (Univ. Calif. Pub. Bot., 1957. 28 (5): 251–334.) 1.75 dollars.

It is well known that much remains to be done in elucidating both vegetative structure and reproduction in the Bangiophycidae, and with only imperfect knowledge classification of these algae is bound to be makeshift to a certain degree. However, the classification given by Kylin is a modification of Skuja's[14] and seems to result in a more natural grouping of genera.

The book is well laid out, has a clear and detailed list of contents which enables the reader to reach the required section quickly and easily, good indexes and list of literature. It is plentifully illustrated, although the figures (many of which have appeared before) are not as well printed as in the "Anatomie der Rhodophyceen". There are typographical slips, many of which have been listed, but considering the circumstances in which the book has come into being, these should be excused. It is unfortunate that its price is so high.

It is not easy to put oneself back into the situation as it was in 1944 when the manuscript of this book existed already, and to view it from that position, as one should do, when evaluating it. Before his death, Kylin had realized the difficulty of incorporating new material into a book which had already been written for some time, and had therefore planned to add a supplement. This task fell to his wife, Elsa Kylin, who carried out the work most faithfully and has thereby made a most valuable addition to the book. This brings the book up to date, and although the reader has to assess the implication of the new work on statements in the main body of the work for himself, this is not difficult to do since it is conveniently arranged. Algologists all over the world will be very grateful to Elsa Kylin not only for this section but also for the immense and successfully accomplished task of seeing this work through the press.

What is the outlook for the next half-century? While predictions of what will be done are clearly unsafe, it is possible to indicate some of the interesting aspects of the study of these plants which deserve further attention. First, in what other groups of plants can one see quite so clearly and extensively the development of elaborate thalli from the basic unit, the branched heterotrichous filament? This is a fascinating morphological study of the first order. Differentiation into main axes and laterals can be seen leading on to differentiation of laterals into ones of limited and unlimited growth, with correlation of the growth of the laterals in the more advanced types.

Secondly, while the basic story of reproduction in the Florideae, characterized by non-motile sexual and asexual reproductive cells and the distinctive female cell the carpogonium, has been known for roughly a century, no comprehensive comparative consideration of the 'female reproductive branch' has yet been undertaken. In attempting this, an investigation of new forms as well as re-investigation of old types would probably be desirable.

Related to this is the parallel study of the carposporophyte, the structure which develops from the zygote, and the chief function of which is to produce spores. One of the unique features of this phase is the transfer of either the fusion nucleus itself or one of its derivatives, to one or more specialized cells of the gametophyte, the generative auxiliary cells. The present state of our knowledge is one of bewildering variety and it will remain in this condition, or get worse, as long as we are without a satisfactory interpretation of the carposporophyte. Investigations have been made mainly with a view to taxonomy, since features in the development of this phase and of the auxiliary cells have been considered, and quite rightly, to be of importance for classification. Now a comparative survey, from the point of view of the lines of its development, organization and specialization, is much needed. Here again, fresh investigations and reinvestigations would doubtless be needed.

Interpretation of the life-histories of the Florideae has always proved difficult. While a parallel might be considered to exist between the carposporophyte of these algae and the capsule of a moss plant, there is still no instance in the red algae in which reduction division has been shown to take place in the carposporangium, although such is often assumed in textbooks. So while the moss life-history can be considered to fall within the Hofmeisterian concept of 'alternation of generations', no known life-history of a red alga can be so considered. This is one of the facts about life-histories of these algae which makes fresh concepts, that is, ones other than those put forward in "Die Gattungen der Rhodophyceen", imperative, as are necessary, in fact, for all algal phyla. Apart from the presence of the carposporophyte is the additional fact that it is haploid in some, for example, *Nemalion*, and diploid in the majority, for example, *Polysiphonia*. Correlated with this is the absence of a tetrasporophyte present in most red algae in the former type. So in the *Nemalion*-type there are two dissimilar somatic phases, the gametophyte and the carposporophyte, both of which are haploid. In the *Polysiphonia*-type there are also two somatic phases, corresponding to those in *Nemalion*, but with important differences. The one somatic phase, represented by the gametophyte only in *Nemalion*, is represented by both the gametophyte and the tetrasporophyte in *Polysiphonia*, the former being haploid and the latter diploid. In *Nemalion*, there is only one nuclear phase, which is haploid, there being only a diploid state of the nucleus and no diploid phase or stage as in *Polysiphonia* where the diploid nuclear phase could be considered to dominate. The other interesting point about the *Polysiphonia*-type of life-history is that the two nuclear and two somatic phases do not coincide, a single somatic phase being haploid or diploid according to its position in the obligatory sequence of events and, although so unlike morphologically, the carposporophyte and tetrasporophyte are both diploid.

Although for most botanists there are two types of life-history in the Florideae, those of *Nemalion* and *Polysiphonia*, there exist many others, some much better known than others, and continued investigations of these will certainly lead to a modification of current views on life-histories. Additional proof of all life-histories by means of culture and cytological investigations is needed. Complete experimental proof of the *Polysiphonia*-type exists for a very few species, and it is conceivable that an attempt to uphold the accepted *Nemalion*-type by culture would fail.

There is therefore room for much interesting work and scope for the formulation and testing of new ideas in this group of algae. Kylin's last work provides a well-equipped base camp from which to set forth.

SOLAR ENERGY: A CHALLENGE TO THE FUTURE*

By Dr. HAROLD HEYWOOD

Principal of the Woolwich Polytechnic, London, S.E.18

EARLY civilizations paid homage to the Sun as the giver of all life; and indeed it is now realized that the radiation emitted by the Sun is the ultimate source of all our heat and industrial power, except for that derived from nuclear origin. The sources of energy that are most easily utilized have been stored by a process of natural concentration. Coal and oil formed by the metamorphosis of living matter represent a concentration in time; water-power derived from elevated lakes caused by the deposition of water evaporated from the oceans represents a concentration in space. Facilities for water-power are, however, limited to suitable regions, while world reserves of coal and oil are decreasing and will eventually reach a stage of serious shortage. Radiation from the Sun, however, is received continuously, and could be used in localities with suitable climates to reduce the importation of expensive fuels and to improve the amenities of undeveloped arid areas.

Direct solar radiation as received at the Earth's surface is relatively low in intensity, though the total magnitude far exceeds that of all other energy resources, for in fourteen days the Earth receives radiation equivalent in heating value to the whole of the estimated world coal reserves. The problems involved in the artificial collection of radiation are mainly caused by this relatively low intensity, the intermittent nature and variable direction of the source. The radiation intensity external to the Earth's atmosphere is remarkably constant, varying only by ± 1·5 per cent of the mean value of 2 cal./cm.^{2}/min., or 430 B.Th.U./ft.^{2}/hr. or 1,350 watts/m.^{2}. There is also a variation of ± 3·5 per cent of the mean value due to changes in the distance from the Sun to the Earth. These variations are insignificant compared with the variation in transmission through the Earth's atmosphere, due to cloud, haze and dust. Even with clear skies, there is still considerable variation due to the relative thickness of atmosphere through which the rays must pass, termed the air mass. The air mass depends on the time of day, season of the year and the latitude of the place considered.

The spectral distribution of the solar radiation indicates that the surface temperature of the Sun is nearly 6,000° C. The maximum intensity is at a wave-length corresponding to green light, and the energy is about equally divided between the visible light range and the infra-red range up to 3 microns wave-length. The atmosphere absorbs nearly all the ultra-violet wave-length and certain bands in the infra-red are almost completely eliminated by water vapour and carbon dioxide.

Economic applications of solar energy are limited to localities in which there is a high proportion of clear sunshine during the winter as well as during the summer. The most favourable areas are mainly situated between latitudes 40° and 20° north and south of the equator; excessive humidity in the tropical equatorial zone is a handicap.

The serious study of solar energy utilization began a hundred years ago, and quite elaborate equipment was built during the early years of the twentieth century. Güntner (Austria, 1854–73) experimented with mirror systems and solar boilers; Mouchot (France, 1860–80) constructed a solar boiler and steam engine, and in 1878 operated an ammonia absorption refrigerator to produce ice by solar radiation. Pifre (France, 1878) constructed an improved mirror system and solar boiler, using the engine for driving a printing press at the Exposition Universelle in Paris. Bessemer (England, 1868) built a solar furnace which will be described later. Ericsson (United States, 1864–88) built mirror systems combined with boilers or hot-air engines, and also developed a number of instruments to measure solar radiation, obtaining a very accurate value for the solar constant, the rate of incidence outside the Earth's atmosphere. Adams (England, 1876) constructed a solar cooker for use in India; Harding (England, 1883) installed a solar distiller for drinking-water supply in Chile, which covered an area of

---

* Substance of a Friday Evening Discourse delivered at the Royal Institution on May 24.

51,000 sq. ft. and operated successfully for twenty years. Other experimenters in the United States built various types of solar engines, and the final stage in this sequence of developments was designed by Shuman (United States) in collaboration with Sir Charles Boys. This was a mirror system with steam boiler, engine and water pump erected on the bank of the Nile at Meadi, near Cairo, in 1912. The total effective area of the concentrating mirrors was nearly 14,000 sq. ft.

Most of the inventors during this early development period used expensive mirror systems to generate steam and hence mechanical power; but fuel was then cheap and plentiful, and although the experiments had some degree of success they were abandoned after a few years. Interest in the subject revived in 1945, due to the increased cost of fuel with the realization that supplies will become more difficult in the future, and also the desire to extend some of the benefits of industrial communities to undeveloped countries which lack natural supplies of coal and oil. Active research was initiated in the United States, but many other countries are now engaged in schemes which have application to their particular localities.

The immediate scope has changed from power development to the collection of solar radiation as low-grade heat, that is, heat at a temperature below the normal boiling point of water. This can be accomplished with relatively simple equipment, and with a collecting efficiency of the order of 60 per cent, whereas there are still many problems to be solved in the generation of solar power, which for inescapable thermodynamic reasons can only have an efficiency of the order 5–10 per cent. This low-grade heat may be used for domestic hot-water supply, house heating at night, distillation to provide drinking water from salt water and eventually for air conditioning and refrigeration, which would be one of the most beneficial applications in tropical countries.

Although this lecture is restricted to a consideration of artificial collectors of solar energy, it should be mentioned that the natural process of photosynthesis by the living plant, itself the greatest and most important user of solar energy, has been fully investigated as regards improvement in the efficiency of carbon fixation, that is, the effectiveness with which the incident sunlight is utilized. This fixation efficiency is very low for natural conditions of growth because so much of the solar radiation falls upon unproductive parts of the plants or on the spaces between the plants; it is less than 1 per cent for an acre of wheat. If, however, a suspension of algae in water is circulated with exposure to sunlight, combined with enrichment of the atmosphere with carbon dioxide and the addition of nutrients, then a fixation efficiency of 5 per cent may be attained. The alga *Chlorella* may be grown in this way to produce food for cattle, and even for human consumption, but it is difficult to envisage that such processes will ever be practicable for fuel production.

The effective use of solar radiation as a source of energy therefore depends on further developments of artificial collectors and heat engine cycles, which will enable the conversion to be made at a cost comparable with that of existing fuel systems.

Operating Principles of Solar Radiation Collectors

Collectors may be divided into two groups: those in which the absorbing surface is fixed in position and which operate by direct illumination without any concentration; and those in which the absorbing surface is combined with a system of mirrors to concentrate the radiation. The latter necessarily rotate to follow the apparent motion of the Sun.

If a plate of sheet metal is exposed to direct solar radiation the temperature will rise until the rate at which energy is received is equalled by the rate at which heat is lost from the plate; this temperature is termed the equilibrium temperature. If the back of the plate is protected by heat-insulating material, the exposed surface of the plate painted dead-black and covered by one or two sheets of glass, then the equilibrium temperature will be much higher than for the simple exposed plate. This plate may be converted into a heat collector by adding a water-circulating system, either by making it hollow or by soldering copper pipes to the surface, and transferring the heated water to a tank for storage. If heat is taken away from the system, however, the equilibrium temperature must decrease, for no useful heat can be extracted at the maximum equilibrium temperature, at which the collection efficiency is zero. The other extreme condition is where the flow of water is so rapid that the temperature rise is very slight; then the losses are small and the efficiency of heat collection approaches 100 per cent, but as the temperature rise is so restricted the system has no practical utility. The optimum conditions are approximately midway between the atmospheric and the maximum equilibrium temperature, whereby an output of water at a useful temperature is obtained and the efficiency of radiation conversion is about 60 per cent. These flat-plate heat collectors are usually mounted on a roof in a fixed position, preferably facing south, and connected to a water storage tank by flow and return pipes so that a natural circulation is produced by the heating effect. Small units may be used for domestic hot-water supply and larger units with a correspondingly increased storage capacity for house heating. The same type of device may be used as an air heater, either for house heating or for the drying of fruit and vegetable crops.

The equilibrium temperature of the flat-plate collector is limited, because the area from which losses occur is equal to the area receiving radiation. If, however, a mirror system of relatively large area is used for concentrating the solar radiation upon a heat-absorbing area of smaller surface area, then the losses are proportionately reduced and the equilibrium temperature raised accordingly.

Whereas the flat-plate collector is in general restricted to a temperature somewhat below the normal boiling point of water, mirrors of sufficient size could theoretically reproduce the surface temperature of the Sun, 6,000° C. This would require a concentration in area of 40,000 (assuming the distance between the Earth and the Sun to be 100 times the diameter of the Sun), and neglecting any loss by reflexion at the surface of the mirrors. Practical applications are at the moment limited to a temperature of about 3,000° C., for which a concentration in area of 20,000 is required. Much smaller concentrations than this, say 10–100, are sufficient to raise steam at pressures above atmospheric, and quite simple mirror systems may be used for solar cookers. Mirror systems are generally in the form of paraboloids or parabolic cylinders.

Applications of Solar Energy

The application of flat-plate collectors to domestic water heating has been mentioned in the preceding section. There are no technical difficulties involved in this application; the problem is entirely an economic one based on the annual heating value of a square foot of roof area, determined by the price of fuel and the cost per square foot of the heat collector. In temperate climates, such as that of the United Kingdom or northern Europe, the annual heat collection per square foot of roof area could be about 1 therm (100,000 B.Th.U.). With coke at approximately 1*d.* per lb. and allowing for the efficiency of combustion, 1 therm of heat would cost about 1*s.*, but with electrical heating at 1*d.* per unit, 1 therm of heat would cost 2*s.* 6*d.* By using mass production methods of manufacture it might be possible to reduce the cost of heat collectors to 20*s.* a square foot, so that this cost could be recovered in eight years by replacing electrical heating, or in twenty years by replacing coke-fired boilers. The latter is not an economical proposition, but the former is just at the balance point, especially as the two methods could easily be combined by using solar radiation for preliminary heating and electricity for the final heating when needed. In contrast, however, to these conditions, in a semi-tropical country it would easily be possible to collect 2 therms/ft.^{2} annually, and electricity costs might be as high as 1*s.* per unit. The annual value of a square foot would then be 60*s.*, so that a solar water heater would recover its capital cost in a very short time.

A similar reasoning applies to house heating, provided that the climate is such that there is a sufficient proportion of winter sunshine. Several solar-heated houses have been constructed in the United States, some with heat storage by water, others using hot air with a large gravel bed for heat storage. A newly designed house at the Massachusetts Institute of Technology will have 80 per cent of the heating load during the year supplied by solar energy.

An office building in Albuquerque, New Mexico, designed by Bridgers and Paxton, has just been completed, in which most of the heating load is supplied by solar radiation. This system incorporates a heat pump to augment the heating in the coldest weather, and this can also be used for air cooling during the hot weather. These designs differ considerably from the conventional house, both in shape and construction, as the layout must incorporate the heat-collecting surface and the large storage capacity required to maintain the heating load during several cloudy days.

Solar-operated water stills for the production of drinking water from brackish water could be of benefit in arid areas such as exist in many parts of the Middle East or in Australia. The design must be cheap to construct, without the need for skilled attention, advantages which are possessed by the roof type of still. In this design the saline water is contained in a flat, shallow tray, which is covered by a roof type arrangement of sloping glass plates. The lower ends of the glass plates lead to troughs placed on each side of the large water tray. Solar radiation evaporates some of the water in the tray and the vapour condenses on the inside surface of the glass plates, so that drops of water run down the sloping glass and are collected in the side troughs. The output is about 1 lb. of distilled water per day per square foot of water tray area, and corresponds to a collection efficiency of about 30 per cent. More complex designs could attain higher efficiencies, but if the capital cost increased at the same rate as the output, no benefit would be obtained.

Mirror systems are used for attaining temperatures higher than the normal boiling point of water, such as are required for cooking. A concave mirror spun from sheet aluminium and about 3 ft. in diameter is the basis of a design by the National Physical Laboratory of India. This has an output equivalent to 300 watts and can be used for boiling or frying; it is intended for use in rural areas where fuel is scarce and will also enable animal waste products to be ploughed back into the land instead of being burnt as fuel. A team working under Prof. Farrington Daniels at the University of Wisconsin has developed similar cookers constructed from thin plastic with a coating of aluminium which has reduced the cost considerably. Solar ovens for baking bread have been designed by Dr. Maria Telkes, and attain temperatures of 350° F.

Although solar power was the objective of many of the early pioneers, there have been comparatively few recent experiments. Nevertheless, small power units for irrigation pumping could replace the very inefficient devices using human or animal power which are still employed in some parts of the world. One of the difficulties is that for an efficient heat cycle the working fluid should have a high temperature, which involves complex mirror-type collectors. The flat-plate type collector with a small degree of mirror concentration is, however, able to vaporize volatile liquids such as sulphur dioxide, which is then used for driving an engine and pump. An installation working on this system has been developed by Italian engineers. Since fuel costs are not concerned, a relatively simple installation, even though of low efficiency, may well prove to be more economical than a complex installation of higher efficiency. It is reported that a solar power plant with a steam capacity of 12 tons/hr. (approximately 1,000 kW.) is to be constructed in the U.S.S.R., where there is an extensive Solar Engineering Laboratory.

Refrigeration and air-conditioning could be the most important applications of solar energy in tropical countries, but in this field also considerable research is needed. The present ammonia absorption systems require a temperature greater than is attained by the flat-plate collector, and though they could be operated by means of a mirror concentrating system, this would complicate the equipment. It is possible that the ammonia process may be redesigned for the lower temperatures or that other working fluids may be discovered.

The direct conversion of solar radiation to electricity is a fascinating prospect. Early attempts to accomplish this were by means of thermo-couples; these are junctions of dissimilar metals or alloys which produce an electric current when one junction is heated and the other cooled. As heat is an intermediate form of energy in the conversion, the process is subject to Carnot's law as regards efficiency, so that a high temperature for the heated junction is necessary to obtain satisfactory outputs. The ideal alloys for the thermo-elements possess properties which at present are conflicting, namely, a good conductivity for electricity and a poor conductivity for heat, combined with a high thermo-electric power. Experiments with existing alloys show efficiencies of 1–2 per cent at hot junction temperatures below 100° C., rising to 6 per cent at temperatures about 300° C.

The barrier-layer photo-voltaic cell converts the photons of light radiation directly into electricity by means of a flow of electrons in a layer of semiconductor. The familiar photocell used for many purposes has a thin layer of selenium as the light-sensitive material, but the efficiency of this type of cell in direct sunlight is 0·6 per cent. In 1954, Pearson, Chapin and Fuller, of the Bell Telephone Laboratories, developed an improved photo-voltaic cell with a silicon layer which converted solar radiation to electricity with an efficiency of 11 per cent. The basic layer of the cell is pure silicon containing one part in a million of arsenic, forming an *n*-type semiconductor. A trace of boron is diffused into the surface of this wafer, and converts the skin into a *p*-type semiconductor. Electron flow is produced when light falls upon the junction between these two layers, and the cell produces 0·6 volt on open circuit when illuminated by direct sunlight. A surface area of 1 square metre of these cells would give an output of 100 watts when exposed to bright sunlight, but the present cost of production limits the use to selected purposes such as power for portable radio transmitters and receivers, and for accumulator charging on telephone systems in remote areas. A substantial reduction of the cost would lead to numerous applications in localities where no other supply of electricity was available.

Solar Furnaces

Concentrated solar radiation was used by the alchemists for experiments on materials at high temperatures, and a system of lenses for this purpose was constructed by Lavoisier in 1772. Large lenses are too expensive and heavy, so that more recent furnace designs use mirrors for the concentration. Sir Henry Bessemer in 1868 constructed a solar furnace by which he was able to melt copper and volatilize zinc, but he abandoned this for more profitable work. Modern solar furnaces, though mainly used at present for research on materials at high temperatures, may eventually be found suitable for certain manufacturing processes.

The most impressive solar energy installation is the large solar furnace constructed by M. F. Trombe at Mont Louis in the French Pyrenees. A flat heliostat mirror is automatically controlled to move and direct the solar radiation along the axis of a concave mirror, 35 ft. in diameter, which is built up from 3,500 separate mirrors individually curved to the correct focus. The image of the Sun, about 3 in. in diameter, is projected into a rotating furnace in which high-grade refractories can be sintered or pure metals melted at temperatures up to 3,000° C.

The individual mirrors consist of segments of flat sheet mirror glass, but in order to obtain the degree of concentration needed for these high temperatures, each segment must be given the curvature necessary to form a focused image at the furnace opening. This is accomplished by straining each mirror by means of a spider frame with a rod passing through the centre of the mirror and a screwed nut for stressing the rod.

The advantage of the rotating furnace is that it may be partially filled with the material to be fused in a granular form, which by centrifugal force is held against the casing of the furnace. The cavity of the furnace acts as a black-body receiver, the innermost layers of material being fused first, and the fusion process gradually spreading through successive layers.

A still larger furnace with a concentrating mirror three times the area of the 35-ft. mirror is now being designed, and trial sections have been constructed. In addition to the existing furnace, M. Trombe has recently installed four smaller solar furnaces with 6-ft. mirrors very similar to that designed by Bessemer. These furnaces are to be available to research workers needing high temperatures for their experiments.

Future Possibilities

Solar energy could be used for almost all the purposes for which coal and oil are used at present, an exception being the field of power for transport. The practical applications of solar energy must be judged against future tendencies in the fuel supply situation and not entirely by present-day economics. Many of the applications which have been described above do not involve new principles, but success is dependent upon careful design and the introduction of new materials and methods of construction as these become available.

The technical problems as regards water heating, house heating and water distillation are virtually solved. When a demand for appliances for these purposes has been established, mass production methods of construction will greatly reduce the capital cost and make them even more attractive as competitors to normal fuels.

There is still scope for research to develop small solar power units using heat engine cycles, and even more so as regards the design of a really simple type of refrigerator operated at a comparatively low temperature. The Bell silicon photocell has great potentialities if only the cost of manufacture could be reduced a hundred-fold. Such an eventuality may be long deferred, but one would hesitate to say that it is impossible. Putnam, in a survey of world energy resources in the year 2050, has estimated that about 10 per cent of the heat required by mankind may be derived directly from solar energy, though only 0·1 per cent of power from the same source. Incidentally, nuclear fuels might at that time supply 60 per cent of the world's power requirements.

A beginning has been made in the study of chemical photosynthesis without the aid of living organisms. Chemical reactions that are promoted by light and are reversible may enable electricity or heat to be produced directly, or may be used for the production of combustible gases. Experiments have as yet been on a small scale, but it is quite possible that discoveries of far-reaching consequence will eventually be made.

It is evident that there is much scope in the future for the study of solar energy utilization. While nuclear energy can solve the power problem for the large cities and industrialized countries where the demands are high and continuous, solar energy may have more prospects of success in sparsely populated areas, especially if these are arid zones without normal fuel resources. As oil and coal gradually become more scarce and costly, so will the economic balance become more favourable for solar energy, and experience gained now may prove of the greatest value in the future. Research on solar energy ranges over many fields of science; the practical scientist could do much to solve the challenging problems of using this inexhaustible supply of energy for the benefit of mankind.

NEWS and VIEWS

Rutherford Memorial Appointments

UNDER the terms of the scheme to commemorate the late Lord Rutherford of Nelson, the following appointments have been made by the Council of the Royal Society: Prof. E. N. da C. Andrade, to deliver the Rutherford Memorial Lecture for 1957, which is to be given in Australia during September–October; Prof. P. M. S. Blackett, to deliver the Rutherford Memorial Lecture for 1958, which is to be given in Canada.

Mr. S. L. Surange, a graduate of the University of Lucknow, now working at the National Physical Laboratory of India, has been appointed Rutherford Scholar for three years from October 1, to carry out research in low-temperature physics at the Royal Society Mond Laboratory, Cambridge.

Royal Society Research Appointments

THE Council of the Royal Society has announced the following appointments: Dr. P. C. Caldwell, to an Alan Johnston, Lawrence and Moseley Research Fellowship, for two years in the first instance, from October 1; Dr. Caldwell will continue his research at the Marine Biological Laboratory, Plymouth, on the relationship between ion movements and metabolism in squid giant axons; Dr. M. J. R. Dawkins, to the Stothert Research Fellowship from October 1; Dr. Dawkins will carry out research in foetal metabolism at University College Hospital Medical School, London.

Royal Society and Nuffield Foundation Commonwealth Bursaries

AWARDS under the Royal Society and Nuffield Foundation Commonwealth Bursaries scheme are announced as follows: Prof. S. D. Chatterjee, professor of physics at Jadavpur University, Calcutta, to enable him to study radiocarbon dating at the Royal Institution, London, and elsewhere in the United Kingdom, for four months from September 1957; Dr. K. Das Gupta, reader in physics, University College of Science, Calcutta, to enable him to work on soft X-ray spectroscopy at Liverpool for four months from June 1957; Dr. H. J. R. Dürr, senior entomologist, department of agriculture, University of Stellenbosch, to enable him to study the taxonomy of South African plant lice (Aphididae) at the British Museum (Natural History) and Commonwealth Institute of Entomology, London, for six months from December 1957; Dr. A. G. Fenton, senior lecturer in physics, University of Tasmania, to enable him to study intensity variations of cosmic rays, with particular reference to solar influences, at the Imperial College of Science and Technology, London, and the National Research Council Laboratories, Ottawa, between June 1957 and June 1958; Prof. Karimullah, professor of organic chemistry and director of the Institute of Chemistry, University of the Panjab, Lahore, to enable him to study natural products research techniques, etc., at Cambridge for about three months from July 1957; Dr. R. F. King, lecturer in geology, University of Birmingham, to enable him to see the application of geophysical methods to the search for oil and minerals and to study rock-magnetism in Canada during August–September 1957; Dr. L. J. Lawrence, senior lecturer in charge of geology, School of Mining Engineering and Applied Geology, New South Wales University of Technology, to enable him to study the latest developments in uranium mineralogy and mineral exploration for about six months at the Imperial College of Science and Technology, London, from January 1958; Dr. J. A. Pople, University lecturer in mathematics, Cambridge, to enable him to carry out research on the theory of nuclear magnetic resonance at the National Research Council Laboratories, Ottawa, during August–September 1957; Mr. J. Shaw, lecturer in zoology, University of Durham (King's College, Newcastle upon Tyne), to enable him to study osmotic and ionic regulation in East African freshwater crabs, at Makerere College, Uganda, during July–September 1957; Dr. J. Smart, University lecturer in zoology, Cambridge, to enable him to study black flies of New Guinea and adjacent islands, collecting there and studying in laboratories in Australia, between August 1957 and April 1958; Mr. H. V. Thompson, a principal scientific officer, Infestation Control Division of the Ministry of Agriculture, Fisheries and Food, Surbiton, Surrey, to assist him to visit Australia during October 1957–June 1958 for the purpose of studying myxomatosis as it affects the rabbit population and indirectly affects predators and agriculture in general.

Statistics at Birmingham: Dr. H. E. Daniels

DR. H. E. DANIELS, whose appointment to the newly established chair of statistics in the University of Birmingham has recently been announced, graduated first at Edinburgh, and then at Cambridge, where he was one of the late Dr. J. Wishart's students in statistics. From Cambridge he went to the Wool Research Association, and there was responsible for some pioneering applications of modern statistical methods to industry. In particular, he there began the work on components of variance which was specially cited in the award to him, this year, of the Guy Medal of the Royal Statistical Society. During the War, Dr. Daniels worked in Cunningham's Air Warfare Analysis Section on the applications of stochastic processes to gunnery problems and on statistical aspects of direction finding. After the War he joined his former teacher as lecturer on the staff of the Statistical Laboratory at Cambridge, and during Dr. Wishart's absence abroad, and since his untimely death (see *Nature*, 178, 294; 1956), Dr. Daniels has been acting director of the Laboratory. In this position he played a large part in building up the course for the diploma in mathematical statistics which has been taken by many of the best of Britain's meagre stock of younger qualified mathematical statisticians. His research interests might best be described as the solution, by methods typical of mathematical physics, of a very wide range of problems of mathematical statistics. His use of steepest descent methods to obtain the distribution of the serial correlation coefficient in the non-null case is a noteworthy example of this, while his contributions to the theory of stochastic processes have been characterized by their close connexion with physical and other practical applications.

Pierre Lyonet (1707–89)

ONE of the great amateurs in natural history and in the art of engraving, Pierre (Pieter) Lyonet was born 250 years ago on July 21, 1707, at Maastricht in the Netherlands. Descended from a French Protestant family that had been driven out of

Lorraine by Louis XIV, he was educated for the Protestant ministry, but took up law instead and became cypher-secretary and confidential translator to the United Provinces of Holland. He is said to have known at least eight languages. In 1742 he published a translation from German into French of F. C. Lesser's "Insectotheologie", with drawings and comments. Having taught himself the art of engraving, he supplied the plates for Abraham Trembley's "Mémoires". His most famous book, which has been described as the most laborious and beautiful example of minute anatomy that has ever been executed, is the "Traité anatomique de la Chenille, qui ronge le bois de Saule", published at The Hague in 1760. It is remarkable for the eighteen beautiful plates depicting his exquisitely delicate dissections of the head of the goat-moth caterpillar (*Cossus ligniperda*). Copies dated 1762 contain an extra plate showing the author's microscope and dissecting instruments, in answer to certain critics who had protested that such minute work was impossible and could not be genuine. Lyonet also studied the anatomy of the sheep-tick, the house-spider and various beetles, and the life-history of Diptera and Lepidoptera. Failing eyesight at the age of sixty put a stop to further microscopic investigations and to engraving. His later researches were published posthumously by W. de Haan under the title "Recherches sur l'Anatomie et les Métamorphoses de différentes espèces d'Insectes" (Paris, 2 vol., 1832). He was a foreign member of the Royal Society of London, and a member of the Royal Academies of Rouen and of Berlin, of the Imperial Academy of Natural History of St. Petersburg, and of the Society of Sciences of Holland. He died at The Hague on January 10, 1789, in his eighty-second year.

Discovery of Element 102

ELEMENT 102, as yet unnamed, has been discovered in the course of a joint research project by scientists from Sweden, Great Britain and the United States. In the experiments performed to make this new element, curium-244 deposited upon a thin foil was exposed to a stream of accelerated carbon ions generated by the 225-cm. cyclotron at the Nobel Institute, Stockholm. The carbon ions included both carbon-13 and carbon-12 particles. Absorption of carbon-13 particles in the curium led to the formation of element 102. The element 102 formed was collected on a separate foil placed near the target foil, along with other atoms produced and ejected by the interaction of the beam of particles and the target. The experiment required very close control of the energy of the incident beam of bombarding ions, since the probability of observing the formation of the new element is critically dependent upon the number of neutrons lost in the reaction; the number of neutrons lost in the reaction is increased, as the energy of the beam is increased beyond the lowest energy at which the reaction begins to occur. Element 102 was identified among the products on the capture foil by radiochemical methods; the isotope identified had a half-life of about 10 min. and emitted alpha-particles with an energy of 8·5 MeV. The isotope probably has a mass of 253 but this has not yet been established with certainty.

The members of the research team were: Hugo Atterling, physicist; Wilhelm Forsling and Lennart Holm, chemists; and Björn Aström, electrical engineer (Nobel Institute for Physics); John Milsted, chemist; and Alan Beadle, chemical technician (Harwell); Paul R. Fields, group leader in the Chemistry Division; and Arnold M. Friedman, who is working at Harwell for one year under an exchange of United States and British nuclear scientists (Argonne).

International Geophysical Year: Broadcast Warning Service

IN order to assist the International Geophysical Year programme the B.B.C. is to broadcast information about the expected solar activity at 11.03 p.m. in the Home Service after the 'news' and before the weather forecast. It will be broadcast by all medium wave and very high frequency transmitters carrying the Home Service. Announcements will be made of the beginning and end of Special World Intervals, and preparatory warnings will be issued. This scheme was put into operation on July 15 and it will continue until the end of the International Geophysical Year (December 31, 1958).

The central World Warning Agency has been established at the United States National Bureau of Standards Radio Warning Service at Fort Belvoir, Virginia. There reports on solar activity from the Central Radio Propagation Laboratory at Boulder, Colorado, will be studied, and when it is considered likely that solar flares or other disturbances will occur on the Sun an 'alert' will be declared. If the activity is maintained a Special World Interval is declared. Should the expected activity fail to occur, the Special World Interval will be cut short. The 'alert' will be rescinded when the solar activity subsides or the active region disappears around the other limb of the Sun. In order to transmit information about the declaration of 'alerts' and Special World Intervals, use has been made of the existing meteorological communication system, which is used for transmitting weather information from one part of the world to another. The World Warning Messages initiated at Fort Belvoir will be transmitted by land-line to the transmitters in New York, Miami and San Francisco, and from there by a network of radio, telegraph and telephone links to meteorological communication centres and thence to International Geophysical Year stations. The messages will be transmitted from Fort Belvoir at 1600 U.T. (Universal Time, which is equivalent to Greenwich Mean Time), and if a Special World Interval is declared it will take effect at midnight on the same day. In Britain the messages will be received by the Meteorological Office Telecommunications Centre at Dunstable, and will be distributed by telegraph to scientific stations by the General Post Office and more widely by the B.B.C. announcements. The United Kingdom Antarctic stations will receive messages by radio from Port Stanley in the Falkland Islands.

Radiation Society of Australia

A HIGHLY successful conference on "Radiation Biology" was held at the Cancer Institute, Melbourne, in December 1955. This conference made apparent the number of people in Australia interested in the effects of radiation, and led to the suggestion of the formation of a Radiation Society. The Society is intended to lead to a better understanding among the workers in the various disciplines involved, and thereby to encourage research investigations. A committee has been elected, and comprises: Sir

Macfarlane Burnet (director, Walter and Eliza Hall Institute of Medical Research, Royal Melbourne Hospital), Dr. A. M. Clarke (Zoology Department, University of Melbourne), Mr. K. H. Clarke, Mr. H. A. S. van den Brenk, and Dr. J. H. Martin (convener) (Cancer Institute Board, Melbourne). A programme of four meetings for the year has been prepared, the intention of these first meetings being to cover fundamental concepts.

Earthquakes in Persia

BEGINNING on July 1, a series of strong earthquakes has caused devastation in the Caspian Sea region, east and north-east of Teheran, in northern Persia. In Shahi the main government building and railway station were damaged. Polour and Olesefid, villages near Demavend, were destroyed. Damage occurred in Larijan, Sangechal, Firuzkuh, Vereek and other towns and villages, including Bandpay and Bulukamiri. In all, casualties may amount to 4,000 killed, 10,000 wounded and 100,000 homeless. Minor earthquakes occur frequently in the district, and major earthquakes have occurred in the district in the past. In 1802 Demavend and Mazandaran and seventy towns and villages in the region were destroyed. Semnan and Damghan suffered great damage. In 1810 an earthquake caused much destruction at Sari. Another earthquake occurred at Demavend in June 1811. Sir Arnold T. Wilson refers to an inscription on the Masjid-i Juma at Barfurush which states that it was destroyed by an earthquake in the reign of Fath Ali Shah. Aftershocks of the present series are still occurring and further news from the area is awaited.

Earthquakes in Turkey

FOLLOWING the earthquakes at Fethiye less than a month ago and in Turkish Thrace on May 10, a severe earthquake shook the Bolu district on May 26 about 8.30 a.m. local time. This (*iP*) was recorded at Kew Observatory at 06 h. 38 m. 52 s. G.M.T. and the earthquake was of magnitude 7. The shock was felt at Istanbul (Bolu is 200 miles north-east of Istanbul) and in many places nearer Bolu. At Bolu there was great destruction of property including the water-works, and in the neighbourhood of Lake Aband, a beautiful summer resort, several villages were utterly destroyed. Three islands appeared temporarily, but later disappeared, and on nearby land there were cracks wide enough for a man to walk in. A mosque collapsed in Chakmacilar village, south of Bolu, and two hundred houses were wrecked in the town of Seben. Altogether some sixty-six people were killed and more than seventy injured. The epicentre was near latitude 41° N., longitude 31° E. and the origin time 06 h. 33 m. 31 s. G.M.T.; there have been more than seven hundred aftershocks from the same (or very near) epicentre. Five people were killed in an earthquake in Bolu in February 1956. Most earthquakes in Turkey are of tectonic origin occasioned by 'Alpine' orogenic pressure. When this pressure builds up so as to exceed that required for rupture, slipping occurs usually along one or more of the ancient geological faults which abound. One such structural line runs through Mürefte, Izmit, Bolu and Gerede, and although earthquakes have their epicentres on it, it also has a great influence on relief and is both a very densely peopled zone and a corridor for communications. One of the greatest of Turkish earthquakes occurred on December 27, 1939, near Erzincan. In this shock 16,629 buildings were completely destroyed, 9,599 partially destroyed, 23,148 people were killed and 8,029 injured (*Nature*, 145, 13; 1940).

Centenary of the Science Museum

DURING the past and present decades many museums have or will celebrate their centenaries. It was a happy thought of the late Dr. F. Sherwood Taylor, director of the Science Museum, London, that the centenary of that Museum, which falls this year, should be celebrated by the publication of a book. Through his untimely death in 1956 it was, however, left to the present director, Mr. T. C. S. Morrison-Scott, to implement the inspiration of his predecessor, and he is to be congratulated on the production of a readable and interesting volume, entitled "The Science Museum: the First Hundred Years" (pp. iv+85. London: H.M. Stationery Office, 1957. 15*s.* net). The first part of the book gives a brief account of the history of the Museum from its inception in the Great Exhibition of 1851, its official opening to the public in 1857 in the 'Brompton Boilers', the opening of the east block by King George V in 1928, to the present day when the opening of the new Museum block is hopefully anticipated for the end of 1961.

It is stressed that the policy of the Science Museum is directed, first, to enlarging our knowledge of the development of science from the earliest times, and secondly, to presenting that knowledge to the visitor. To these ends the Museum has gathered together a collection of historic scientific and technological objects unsurpassed anywhere in the world. The second and larger part of the book is thus appropriately devoted to short descriptions of twenty-one of these historic objects. These have been selected with discretion, and include the Wells Cathedral clock (1392), the original Davy lamp (1816), the Pyrophone (*c.* 1874), the Rolls-Royce motor-car (1905) and the Whittle turbo-jet engine and Gloster aircraft (1941). The book is amply illustrated and is another example of the imaginative format which now characterizes the publications of H.M. Stationery Office.

Zoological Society of London

IN 1951 an ambitious plan for rebuilding the Society's Gardens in Regent's Park and for further developments at Whipsnade were announced. The implementation of this plan had to be deferred until the necessary financial resources were available. The Council of the Zoological Society has now commissioned Sir Hugh Casson to prepare, in association with the Society's architect, an alternative sketch plan for the rebuilding of the Regent's Park Gardens. The ultimate object is to transform the Gardens in such a way that the north end of Regent's Park becomes a major feature of London, both architecturally and from the landscape point of view, as well as the finest zoological garden in Europe. This proposal is described in the annual report of the Zoological Society (Report of the Council and Auditors for 1956. Pp. 63+4 plates. London: Zoological Society of London, 1957), which, besides all the relevant details of finance, visitors, new acquisitions and publications, explains the arrangements which have been made with Granada Television, Ltd., for the installation of a television unit in the Society's gardens.

Harwell Course on Isotopes in Industry

The Isotope School at Harwell is arranging a three-day course, during September 25–27, for directors and senior executives from industry, on the uses to which radioisotopes can be put. The course will include visits to the Harwell reactors and to the Wantage Radiation Laboratories, where research is progressing in the use of large radioactive sources for the irradiation of foodstuffs, pharmaceuticals and other manufactured articles. There will be talks on safety precautions to be taken when using radioactive material, and on aspects of turning an ordinary laboratory into an 'active' laboratory. Lectures will give sufficient background information to enable non-technical executives to appreciate the possibilities of the use of radioisotopes. The emphasis throughout will be on the practical uses of isotopes and irradiation sources in industry. Accommodation can be arranged at Worcester College, Oxford. The fee for the course will be £30 inclusive of all accommodation, transport, and meals. Forms of application and further information can be obtained from the Registrar, Isotope School, Atomic Energy Research Establishment, Harwell, Berkshire.

British Museum (Natural History) : Appointments

Dr. W. E. China, keeper of the Department of Entomology in the British Museum (Natural History), has been appointed a deputy chief scientific officer in succession to Dr. H. W. Parker (who has held that office in conjunction with the keepership of zoology); Dr. Francis Charles Fraser has been appointed keeper of the Department of Zoology in succession to Dr. Parker; and Mr. James David Macdonald a deputy keeper in the Department of Zoology; all with effect from October 1.

University News :

Birmingham

The following appointments in the University of Birmingham are announced: Dr. W. I. Stephen, to be lecturer in chemistry from October 1; Dr. J. Wilcock, to be lecturer in industrial metallurgy from October 1; W. B. Powell, to be staff fellow in the Department of Physics from November 1; Dr. P. C. Harris, to be lecturer in medicine from July 1; Dr. K. Brown-Grant, to be lecturer in physiology from August 1. The title of reader in organic chemistry has been conferred on Dr. J. C. Tatlow.

London

Dr. H. C. K. Henderson, senior lecturer at Birkbeck College, has been appointed to the University readership in geography tenable at that College; and the title of reader in physics in the University of London has been conferred on Mr. W. R. S. Garton in respect of his post at the Imperial College of Science and Technology.

Sheffield

A gift of £25,000 has been made to the University of Sheffield by Imperial Chemical Industries, Ltd., towards the cost of building extensions to the Departments of Chemistry and of Fuel Technology and Chemical Engineering. The chemistry block in Brookhill, opened in 1954, was the first new teaching building to be erected under the University's development plan, but its capacity has already been overtaken by the increasing numbers of students. Plans have been prepared for the addition of an east wing with large teaching laboratories and a west wing for staff and research rooms. The first part of these extensions is due to begin this year. The Department of Chemistry is the largest in the University and had more than 550 students during the session 1956–57. The Department has not only to train specialists in chemistry and carry out fundamental research, for which it has acquired a distinguished reputation, but must also provide basic teaching for other students in the four Faculties of Pure Science, Medicine, Engineering and Metallurgy. It is in fact one of the key departments in the training of scientists and technologists. The Department of Fuel Technology and Chemical Engineering has for many years carried out valuable work in very cramped conditions at the University's Applied Science buildings at St. George's Square. In order that work on the efficient use of fuel and other industrial problems may go ahead as rapidly as possible considerable extensions to the Department's premises will soon be put in hand.

Announcements

Sir Charles Lillicrap, a former director of naval construction of the Admiralty, and Mr. John Strong, chairman of Quasi-Arc, Ltd., have been re-elected for a second year as president and vice-president, respectively, of the Institute of Welding.

Prof. A. C. Frazer, professor of medical biochemistry and pharmacology in the University of Birmingham, has been re-elected president of the British Food Manufacturing Industries Research Association.

Dr. Ralph W. Phillips, deputy director of the Agriculture Division of the Food and Agriculture Organization of the United Nations, has resigned to take up a new appointment as director of the Division of International Organization Affairs in the Foreign Agricultural Service in the United States Department of Agriculture. Dr. Phillips, a distinguished agriculturalist, has served with the Food and Agriculture Organization for more than ten years.

The Royal Society of Edinburgh has awarded a Robert Cormack Bequest Fellowship in astronomy to Miss Patricia R. R. Leslie, of Edinburgh. The Fellowship will be tenable for three years at the Cavendish Laboratory, Cambridge, and Miss Leslie will undertake research there, under Mr. Martin Ryle, into the distribution of the sources of extra-terrestrial radio emission. Miss Leslie is a graduate in pure physics of the University of Edinburgh.

The following have been elected to office in the Physical Society for the session 1957–58: *President*, Prof. N. F. Mott; *Honorary Secretaries*, Dr. C. G. Wynne, Dr. H. H. Hopkins; *Honorary Foreign Secretary*, Prof. E. N. da C. Andrade; *Honorary Treasurer*, A. J. Philpot; *Honorary Librarian*, Dr. R. W. B. Pearse; *Vice-Presidents*, Prof. S. Devons, Prof. F. Llewellyn Jones, Prof. H. Jones, and Dr. K. A. G. Mendelssohn.

The Chemical Research Laboratory, Teddington, Middlesex, is to hold three open days during October 1–3. Applications from firms for invitations should be sent to the Director not later than August 31.

Erratum. In the article entitled "Some Recent Advances in Spectroscopy" in *Nature* of June 29, on p. 1342, col. 2, line 51, for "lithium–potassium spectrum" read "lithium *K*-spectrum".

RESEARCH ON METAL COATINGS

BRITISH IRON AND STEEL RESEARCH ASSOCIATION, SOUTH WALES LABORATORIES

IN 1932 a research group was set up in the Metallurgy Department of University College, Swansea, to study various aspects of sheet steel production. It operated under the auspices of the South Wales Siemens Steel Research Committee and the Welsh Sheet and Plate Manufacturers' Association and was led by Mr. D. Luther Phillips.

When the British Iron and Steel Research Association was formed in 1945, it absorbed this research group, the functions of which were carried on by the Association's Mechanical Working Division. The policy of the British Iron and Steel Research Association had been to site its laboratories in areas traditionally devoted to specialized aspects of ferrous technology, so that it was natural that its Coatings Laboratory should be set up in South Wales, which is the main centre of the flat-rolling, tinning and galvanizing industry. In 1946 laboratory accommodation was obtained at Sketty Hall, a large building in Singleton Park, close to University College and about four miles from Swansea. A Pilot Plant Laboratory has recently been added in a building adjacent to Sketty Hall to house small-scale continuous strip-coating and processing plants. Mr. Phillips retired in 1954 and research is now directed by Mr. S. S. Carlisle.

The research programme of the Coatings Laboratory works in two main fields. It endeavours first to develop new and improved coating for steel, so as to extend the applications of steel products, and secondly, it seeks to improve such existing processes as strip tinning, galvanizing, aluminizing and lacquering in order to reduce costs and increase productivity. The ultimate aim is to prepare the way for automation in the steel strip finishing industry.

The many projects currently being studied at Sketty Hall were displayed at open days, held on June 19 and 21, when representatives from the iron and steel and allied industries toured the laboratories. A short description of the main displays is given here.

Research has been undertaken into coating steel with plastics, so as to combine the strength of steel with the attractive and durable finish of the plastic. An improved process has been devised, whereby a film of polyvinyl chloride is bonded to steel, the laminate so formed ('Plasteel') being amenable to bending, deep drawing and roller forming without harm to the plastic film. A pilot line is producing continuous strip laminate up to 3 in. wide in a variety of plain, coloured or embossed polyvinyl chloride on steel. The process is being patented, and wide interest has been shown by potential users of the new material.

It is an advantage in can-making to be able to apply a thicker coating to the inside than to the outside of a can, since the interior may be subjected to corrosive action from acid fruits. A problem in subsequent working of the tinplate is to identify which side has the thicker or thinner coat. A method developed by the Association, and being patented, is to dull one side by applying a thin electrodeposit of iron (about 0·25 micro-inch thick) after tinning but before flow brightening.

Lacquered steel has been found suitable for use in can-making where protection against corrosive fluids, other than acid fruits, is required. Although this is a useful technique when tin is scarce, lacquered steel has the disadvantages that it presents no tinned surface for soldering, it cannot be used for all food-packs, and the lacquer is easily damaged. However, it is now possible to tin the edges for soldering, and to lacquer one side of a sheet and tin the other. The British Iron and Steel Research Association has built an experimental line for lacquering steel strip, on which coatings of epoxy-resins up to 0·5 mil thick can be applied and cured by heating. A coating as little as 0·15 mil thick has been found to protect steel.

Thick coatings are more economically applied by hot-dip coating than by electro-deposition. The hot-dip technique also opens up the possibility of its application to high-speed strip working. Many studies of hot-metal coating practice have been made at the Laboratories, and a new method of hot-strip tinning has been developed.

It was decided to investigate applying tin to steel strip by roller coating, when the weight of tin applied could be controlled by varying the speed of the roller relative to the strip. An experimental continuous strip-coating line using this principle has been built, and good-quality coatings have been applied at speeds of up to 50 ft./min. Lead–tin alloy has also been successfully applied.

The process opens the possibility of cutting costs in tinplate production by placing the hot-tinning mechanism at the end of a continuous strip-annealing line. It may also be possible to use the process for applying such other coatings as zinc and aluminium, and it has therefore been decided to develop it further. To this end a 12-in.-wide strip-processing plant has been built, similar in principle to the small experimental line. It is capable of speeds up to 1,250 ft./min. and is fully instrumented.

A method for continuously coating steel strip with aluminium has been developed in the Laboratories, so making available a material generally resistant to corrosion and useful at temperatures too high for tin or zinc coating. The 'Sendzimir' process, which has been successfully operated in America, is mainly suitable for large-scale production of coated sheet, for which there is as yet insufficient demand in Britain. In the Association's method, continuous strip up to 3 in. wide has been successfully coated, and the difficulties normally encountered in the past from oxidation of the ingoing strip have been overcome. The surface of the strip is carefully prepared and coated with glycerol; it enters the aluminium bath through a protective box, preventing the oxide film which forms on the surface of the bath from reaching the strip. By burning the glycerol the strip is kept free from oxidation before entering the bath, also, and the addition of small amounts of silicon to the bath inhibits the formation of brittle iron–aluminium alloy on the steel surface. One firm has applied the Association's process to the manufacture of aluminized steel wire; aluminized steel, with its negligible tendency to scaling and its good anti-corrosion properties, will probably become a material of greater application in the future.

Copper wire is being coated by drawing it through a die, the entry side of which is flooded with molten tin. Provided that the wire surface is clean and freshly drawn, no flux is needed; uniform coatings about 40 micro-inches thick with reductions in wire diameter of 5–10 per cent have been obtained and drawing speeds are about 100 ft./min. The process is being patented.

A necessary preparation for steel sheet or strip before working or coating is 'pickling' by immersion in sulphuric acid, which has the effect of removing the surface oxide film. The severe shortage of sulphuric acid a few years ago, coupled with the problem of disposing of spent pickle liquor, led the Association to investigate the possibility of recovering acid from waste liquor. This is achieved by precipitating ferrous sulphate monohydrate from the liquor by evaporation, roasting the sulphate to sulphur dioxide, and oxidizing this to sulphuric acid in a contact plant using vanadium as catalyst.

Several difficulties were encountered. Research had first to be undertaken to determine the practical limits to the removal of ferrous sulphate from acid solutions. The solubility curves so produced were an original contribution to the literature since the published data had been found inconsistent. Then it became evident that the relatively small output of sulphate from pickling lines made it uneconomic to use the contact process for its conversion to sulphuric acid. The Laboratories therefore developed an alternative process of autoxidation.

In this method, sulphur dioxide is released from the ferrous sulphate by roasting with coal and is then dissolved in weak acid circulated through an absorber tower from an acid storage tank. The acid with sulphur dioxide in solution is then aerated by having small bubbles of air blown through it. This takes place in a diffusion tank and the oxidation of sulphur dioxide to sulphuric acid occurs at the bubble–liquor interfaces, catalysed by manganese sulphate which has been added. The liquor is thus enriched in acid, which is drawn off to storage tanks for supply to the pickle line. The iron oxide residue from roasting the sulphate can be used as blast-furnace feed.

Trials on a pilot plant indicated that the process becomes economic when 10 tons or more of acid are being handled. With acid strengths above about 23 per cent the catalyst needs to be kept active by injecting a little ozone with the diffuser air; acid strengths of up to 40 per cent can then be provided. A plant has been designed which could treat all the ferrous sulphate processed at the Trostre tinplate works of the Steel Company of Wales, Ltd., and this design is now being considered. A plant has been proposed, also, for a closed-cycle pickling system with acid recovery using this autoxidation process.

VACUUM DEPOSITION OF METALS

A MEETING organized by the Department of Physics of the University of Cambridge and the British Scientific Instrument Research Association was held in the Cavendish Laboratory on May 17 and 18 by invitation of Prof. N. F. Mott. Attendance was by invitation, and scientists were present from the Imperial College of Science and Technology, London, the University of Bristol, Tube Investments, Ltd., the University of Cambridge and the British Scientific Instrument Research Association.

In the first paper of the meeting, Dr. D. W. Pashley (Tube Investments) described recent experiments on the occurrence of epitaxy in deposits of copper, lead and thallium on crystalline substrates. Dr. Pashley's experiments showed that, while the nature of the initial deposit varied, according to the metal, from a uniform monolayer to a scattering of widely separated atom aggregates, the crystalline form was always that of the metal itself, undistorted by the supporting crystal, which, nevertheless, imposed a regularity of orientation. Later in the discussion, Dr. M. Blackman (Imperial College) examined the relation, for a wide range of materials, between epitaxy and the degree of misfit between the lattice structure of the film and its substrate, and showed that in contradiction to the theory of Frank and van der Merwe there appeared to be no critical degree of misfit above which orientation of the film could not occur. Following Dr. Pashley's paper, which also included a mention of a new technique for revealing dislocations by means of a moiré pattern, Dr. A. J. Forty (Tube Investments) gave evidence of the role of crystal boundaries as sites for nuclei from which the growth of films could start.

Dr. K. M. Greenland (British Scientific Instrument Research Association) described in general terms the work which is being done from the point of view of new and improved detecting elements, and explained that, in the first instance, the British Scientific Instrument Research Association is concerned with the binding forces between films and their substrates with special reference to gold and silver on glass and silica.

Dr. J. W. Mitchell (University of Bristol) described an investigation of the texture of copper films deposited by evaporation at very low pressures on glass held at the temperature of liquid nitrogen. The surface area of the film was measured by an adsorption method. In these experiments it was found that the porous structure of the film was independent of the thickness. As the temperature of the film was raised the structure became more compact, but the admittance of oxygen had a strong stabilizing effect.

Mr. D. G. Anderson and Mr. J. E. Knowles (both from the British Scientific Instrument Research Association) continued the account of work at the laboratories of the Association. Mr. Knowles gave a description of a method which was being investigated for the comparison of the energy released when gold films condense on substrates of differing kinds. This method might lead to a direct measurement of the energy of reaction between the gold film and the substrate. Mr. Anderson showed how chemical bonds might be formed between metal films and a silica or glass substrate and described some experiments designed to demonstrate the importance of oxygen in film bonding. Taking account of the ionic nature of the glass structure, the possibility of the existence of reactive ionic centres in a fractured glass surface was also considered. Prof. F. C. Frank (University of Bristol) summarized the Frank–van der Merwe theory of critical misfit in epitaxy and also discussed the stability of nuclei of cubic crystal forms.

CHEMICAL ENGINEERING EDUCATION

THE symposium on chemical engineering education held at the University of Birmingham during April 9–11 should, as Mr. J. A. Oriel pointed out, be regarded as a domestic sequel to the conference sponsored by the Organization for European Economic Co-operation held in London in 1953. The symposium was arranged in four sessions covering the requirements of industry, methods of training, new trends in teaching, and recruitment to the profession.

After a welcome to the University and in particular to the new chemical engineering buildings by Prof. F. H. Garner, the first session was opened by Dr. D. Clayton (Imperial Chemical Industries), who spoke of the demands of the chemical industry. He explained that the new graduate may be employed in research, design or operation of plant and will receive training in all these spheres during his early years with a company. For this and other reasons, Dr. Clayton voiced the view generally supported by others, and certainly by the educational members at the symposium, that universities should concentrate on fundamentals. The additional technological training required can best be obtained 'on the job', provided that the graduate is already well grounded in basic sciences. In discussing postgraduate work, he felt more use should be made of the M.Sc. degree, as this gives a man an insight into research which is adequate for the majority. He explained that the chemical industry employs people with various forms and level of training, and that it is most important to have an adequate number of assistants if the maximum use is to be made of the best honours graduate. Prof. K. G. Denbigh later made reference to the lack in Britain, as compared with North America, of a large body of men trained just below honours standard.

Dr. F. Mayo (Esso) gave a clear indication of the urgent need for more chemical engineers when he stated that, of its combined intake of scientists and technologists, his company would like some 50 per cent to be chemical engineers, whereas it was only getting some 20 per cent. While welcoming the Government's new plans for technical education, he would press not only for their speedy implementation, but also for further consideration as to whether they are in fact adequate. Dr. Mayo stressed that the ideal process engineer needs imagination and an appreciation of the way in which another man's work influences his own. This can be achieved by movement of the young graduate through various departments, such as plant technical service, plant economics, process design and plant operation. It was his view that men trained in chemical engineering were much more flexible and easier to rotate than those trained in pure science. This is one of the reasons why men with this training are in such demand. He reiterated the point that the university graduate fails mainly in his lack of ability at writing reports and suggested that it takes his company about two years to correct this. He also thought that the American graduate settles down to active work rather more quickly than the British.

Mr. A. S. White (U.K. Atomic Energy Authority) explained the needs of the various Government departments with particular reference to the atomic energy establishments, which employ the greatest number of chemical engineers. In the research departments the main need is for good honours graduates, many of whom should have taken a research degree. There is a smaller need for the plant-manager type but an urgent need for design engineers. Here Mr. White put in a plea for more men with mechanical engineering training, such as might be obtained through a graduate apprenticeship. The experimental officer class provides a good opening for those who do not take honours degree courses.

The requirements of the chemical plant industry were put by Mr. J. P. V. Woollam and Mr. J. D. McFarlane (Simon Carves), who described the execution of a typical contract through the design, construction and commissioning stages, and they then outlined the qualities required by men taking up this type of work. They would like to see more graduates with a sense of cost consciousness, and they suggested that in the vacation the undergraduate should seek experience of general heavy engineering.

In opening the discussion, Sir Harold Hartley indicated the wide range of activities of the chemical engineer and his place in the optimizing of flow sheets. Chemical engineers by training are suited to making the right compromise in design. He felt that Dr. Clayton and Dr. Mayo rather under-rated the importance of research, because it is vital to have men coming forward who know where research can help. Dr. E. H. T. Hoblyn felt that the chemical engineer must do more on design, and that he was well fitted by wide training to be a project co-ordinator. He did not think that young engineers should become too divorced from plant itself and he regarded design problems as valuable in this respect. Prof. F. Morton went straight to the heart of the problem of the supply of teachers. If industry really wants more chemical engineers then it must make greater contributions to the universities. The lending of a few men to the universities to act as temporary academic staff for the next few critical years would make an enormous difference to the rate of growth, particularly of the newer departments in this subject. It would, he argued, be a good investment by industry.

Methods of Training

It is now clear that the majority of new graduates will have taken the undergraduate course, usually of three years. In discussing this type of course, Prof. F. H. Garner explained that, as the chemical engineer is primarily concerned with process industries, he should be trained to appreciate process design and plant efficiencies. On the operational side he must be introduced to efficiency of production and shown that this is effected by considerations of utilities, yields, human relations, and reliability of plant, as much as by pure technical calculations. The young chemical engineer must be trained to make decisions based on physical and chemical relationships, but he must learn that these relationships often have to be extended beyond their precisely known limits in order to solve problems in the time available. In that the chemical engineer would have to work with scientists of widely different training, he suggested that it is preferable for him to learn chemistry with the chemists; but in the discussion some members thought that more of the training should be in the hands of the chemical engineering department. The design problem he regarded as particularly suited for tutorial instruction and it also provides an opportunity for the student to correlate much of his learning.

The development of the postgraduate diploma course was discussed by Prof. M. B. Donald (University College, London). This course had been formed by a marriage between chemistry and engineering, but the engineering content had been small. Of those taking these courses, some 95 per cent had previously studied chemistry, and there is little doubt that training in physical chemistry forms a valuable introduction to many features of chemical engineering. Mechanical engineers have a more difficult road in this respect. The main problem to-day is that the content of chemical engineering has been so extensively expanded that it is difficult to fit diploma candidates into the final year of the undergraduate course. There are special advantages in these courses for those who have been for a year or two in industry.

The position of the subject in technical colleges was given by Dr. P. F. R. Venables (Birmingham College of Technology). The number of candidates taking part-time courses is small, but the percentage of successful candidates has been high. There are eight colleges running these courses, but the response from industry has been small. Dr. Venables thought that the newer sandwich courses were more suitable for chemical engineering. The advantages of obtaining first-hand experience of industry at the same time as taking an academic course seem considerable in this subject. The total content of knowledge demanded by modern professional qualifications made it increasingly difficult for a man to train for these qualifications on a part-time basis. The part-time system is no longer adequate for educating modern technologists as distinct from providing a minimum training for them.

Mr. G. U. Hopton (North Thames Gas Board) explained the many difficulties of the lone man studying by private study. Such candidates for the examination for associateship of the Institution of Chemical Engineers should have trained in chemistry or in engineering by formal study before starting private study in chemical engineering. It is also essential for a man to be engaged in work of a chemical engineering nature.

New Trends in Teaching

Prof. E. S. Sellers (Swansea) explained the importance of mathematics as a tool in design, whether in analysis or in synthesis. Physical design, including the optimization of variables, cannot be done successfully without mathematical tools, and the teaching of mathematics must therefore be associated with its physical and chemical applications. He outlined a three-year course, the main feature of which was the integration of mathematics with chemical engineering in the last year, when the application of mathematics would be given by the chemical engineering department mainly in the form of problems.

Thermodynamics was indicated by Prof. K. G. Denbigh (Edinburgh) as one of the basic studies of chemical engineers. He suggested that a generous provision should be made for this work, both because of its utility and also because of its educational value. It was important to give a real discussion of fundamentals, as the natural inclination of engineering students was to concentrate on the application of a tool. He indicated the application of thermodynamics in several parts of the subject, including its less generally realized use in the calculation of manufacturing processes.

Dr. F. Rumford described the practical training scheme run by the Royal College of Science and Technology, Glasgow. There is no doubt that practical training on industrial units for a short period forms an ideal complement to the theoretical training of the lecture rooms. Realization of some of the difficulties with large units assists the beginner in forming an opinion of the merits and limitations of theoretical work. It must be remembered that these courses do not, and cannot, provide real training in plant operation, and the industrialists must be prepared to provide extended practical training for all graduates. This is one of the difficulties facing small firms, but there can be no doubt that careful training schemes will bring out the best in the new recruit. Plant manufacturers are equally involved in this problem.

Prof. J. M. Coulson (Durham) traced the changing attitude to unit operations, which had been the basis of the initial courses in this subject. The main change in the past fifteen years had been in the co-ordination of these operations and their reclassification as aspects of heat transfer, mass transfer and momentum transfer. In so doing we had created chemical engineering science, in which the study of the basic mechanisms of interphase transfer was predominant. With regard to the future, he suggested that it would be wrong to regard chemical engineering science as synonymous with chemical engineering. He put in a plea for encouragement of the inventive mind, particularly with regard to new forms of equipment. Men leaving British educational establishments should not only have a feeling for cost consciousness but also a sense of urgency.

Opportunities and Recruitment

The third session, on recruitment to the profession, was opened by Mr. A. A. Part (under-secretary, Ministry of Education), who, in speaking of the technological awakening, indicated the brighter prospects for technological training. He warned the conference that the opportunities for chemical engineers must be brought home much more strongly to school-boys and their parents. A strong and up-to-date pattern of courses must be developed which must receive determined support from industry. Mr. Part mentioned that the so-called 'post-war bulge' will increase the numbers in the eighteen-year-old group, from the present figure of 640,000, to 850,000 in 1965. The increasing tendency, 5 per cent per annum, for boys and girls to stay at school until the age of eighteen will further increase the number of potential university and technical college students. With regard to quality, he noted that 51 per cent of the State scholarship winners of 1955 were going to read science or technology. The schools had moved over to science, but the need now is for a move to technology. He was particularly anxious that the profession should make a clear statement regarding its demands for space in the technical colleges, as preparations must be started at once.

Mr. R. Groves (High Master of Dulwich) gave a most interesting account of science-training in British schools, emphasizing that science is now firmly established as a desirable course. The aim is to produce cultured young people who are educated as well as trained in vocational subjects. In the sixth form all should be devoting some time to writing English and to studying a foreign language. He asked industrial members whether they could not do more for the science masters at the schools, perhaps by providing some possibilities for research, but certainly by showing a real interest in them. He took the opportunity of thanking industry for making so marked a contribution to the problem of laboratories in the independent schools.

Mr. J. A. Oriel (president of the Institution of Chemical Engineers) maintained that the opportunities for chemical engineers are excellent and that the profession is showing a most vigorous growth. He claimed that Britain needs at least five times as many chemical engineers leaving the various educational establishments as at present, and that the opportunities for new recruits are excellent. The process industries throughout the world are experiencing a period of outstanding growth, and central to their progress lies the chemical engineer. Referring to the petroleum industry, Mr. Oriel instanced the developments in the past thirty-five years, but he believed there was an even brighter future ahead. In Britain, chemical engineers are almost equally divided between research, development, construction and operation. In North America, with its longer period of development in this field, chemical engineers are in administration in a greater proportion than chemists or other engineers.

In reviewing the symposium, Prof. D. M. Newitt (Imperial College of Science and Technology) thought that industrialists were right in placing emphasis on character development rather than on functional efficiency, but he maintained that a period of post-graduate studies was of greater value than indicated by the industrial members. He thought that we should probably change the nature of our training even more rapidly. Present syllabuses tend to be a legacy of the past and could with advantage be given a new look. Chemical engineering science could conveniently be regarded as a link between physical sciences and technology, and he gave a brief outline of proposals on these lines, in which the traditional studies of mechanical and electrical engineers were merged into chemical engineering science.

J. M. COULSON

WOMEN IN INDUSTRY

WHEN the history of the twentieth century is written, the year 1957 will surely be noted, *inter alia*, as the one when women really began to press their claims for equal career opportunities with men. Their efforts to secure equal social rights through equal educational opportunities has met with considerable success, and, within a few years, they should achieve equal material rewards for equal work. In many activities, and especially in the professions, they have reached positions of eminence and few doors still remain closed to them. In one sphere, however, they have made little progress. This, of course, is the world of industry, and during the past few months the voice of woman has been raised in many parts of the world protesting against the domination of man in industrial and commercial activities. In Britain that voice has been heard at various conferences and courses, while powerful arguments for career emancipation have been propounded in all kinds of journals.

It was appropriate, therefore, for the British Federation of University Women to form a working party to examine all the opportunities open to girls and women with qualifications in science and technology. Its report* has now been published and contains details of jobs available to girls and women in industry, the professions, agriculture and the Armed Forces. The compendium has been painstakingly prepared, and, in the section dealing with openings in the professions and Armed Forces, will be invaluable to headmistresses and university authorities, parents and girls in their formative years; details of jobs are accompanied by details of qualifications needed to fill them.

In the sections concerned with opportunities in industry, however—and these are very few in a report of this size—the working party has been less than fair to members of their own sex who wish to take up work in industry. Perhaps it was unfortunate that only one of the working party of twenty-four women appears to have had definite experience in industry and that in a specialist job.

If the working party had included one or two women members with experience of management in industry—the managing director of Boxfoldia would have been an excellent choice—more attention might have been paid to the very real difficulties confronting a girl who is keen on an industrial career. Although there is still considerable male prejudice against the employment of able women in industry, not all men are prejudiced; there are real difficulties and these must be squarely faced if they are to be overcome.

First, women, like men, would have to see that, although it has other functions, industry must make profits or it would cease to be. The comparative security of the past twenty years has led to great emphasis on the 'service' aspects of industry. This is surely right and cannot be over-stressed. But manufacturing industry can never be a service in the same sense as a profession like medicine, and the competitive element cannot be eliminated. Aspiring women, therefore, should be clearly told that, while industry overall has a social purpose, many industrial firms fail every day and many more are likely to do so. They should accept, too, that industry has not settled patterns of promotion like many professions and the Armed Services and that, even to-day, many men in senior positions have little formal education or training; the secrets of success in industry are still far from clear.

It should also be made clear that many of the openings in industry described in the report will lead to important specialist positions in industry but not to senior positions; the latter will still go to those who are able to co-ordinate the work of the specialist. It is surprising that a report of this kind could be prepared without including the word 'management'; that appears to be the case. Women graduates, too, should be warned that in many industrial organizations which employ male graduates, the latter are finding it difficult to make headway against traditional rule-of-thumb methods of management.

The real difficulty, however, which must be overcome before women are accepted in senior positions in industry is the question of marriage and child-bearing. These topics are not mentioned in the report. Yet if a manufacturer is faced with two people for a key appointment, he is unlikely to provide expensive training for one on whom the odds of leaving are much greater than the other. It is little use telling him that this training will not be lost to industry as a whole; he looks at his balance sheet and there may be a loss to him.

---

* Opportunities for Girls and Women in Science and Technology. 2s. net.

Such manufacturers will only take women applicants when there are no suitable male applicants. Fortunately for professional women, that condition has already been reached in many branches of British industry. Women will be accepted because there is no other choice. Women should think carefully, however, before deciding on particular careers in industry. In such careers as general management, personnel management, and industrial medicine, a break for marriage and child-bearing should be no handicap and should enable the middle-aged women to return to industry even more fitted for her job. In rapidly evolving specialist fields, however, where knowledge of chemistry, physics and other natural sciences are involved, she may find it easy to secure a post before marriage but difficult to return to it afterwards.

Women who wish to find employment in industry may find this report disappointing; they should be consoled by the knowledge that industry can no longer do without them.

EARLY HISTORY OF THE SAUROPSID REPTILES

In palaeontology, as in other branches of science, small things often lead to great and far-reaching results. It is not unexpected, therefore, that Prof. D. M. S. Watson, with his usual searching eye and his vast knowledge of reptilian structure, should develop some significant conclusions from his study of eight small reptilian skulls and associated skeletal materials, contained in a nodule of rock from the *Cisticephalus* zone of the Karroo series of South Africa. These fossil remains, representing the genus *Millerosaurus*, are described in detail in a recent paper* by Prof. Watson in which he turns to a discussion of the basic classification and the relationships of all the reptiles.

Millerosaurus, as Watson shows, is a small fossil reptile with a long body and slender limbs. The skull is basically cotylosaurian, but it has a well-developed lateral temporal fenestra, situated beneath the post-orbital and squamosal bones. A part of the skull roof is covered with bony osteoderms fused to the underlying skull bones, and at the back of the skull the quadrate is characterized by a long ascending process rising to the supratemporal bone. In the area behind these bones is a small stapes, quite comparable to the stapes of a lizard, which in life must have formed a communication between a large tympanic membrane and the fenestra ovalis. The pectoral girdle has a 'screw-shaped' glenoid, and in the hind foot the fifth digit is complete and divergent. The fifth metatarsal is straight—not a hook-shaped bone. Such are a few of the bare facts concerning the osteology of *Millerosaurus*. What are the implications?

In 1916 Goodrich saw a basic dichotomy within all but the most primitive reptiles, the two branches of which he designated the Sauropsida and the Theropsida. Watson upholds this view of reptilian evolution, and he places *Millerosaurus* and its relatives as very important ancestors of sauropsids. In line with previous work, he believes the ear region to be of particular diagnostic value in the determination of sauropsid and theropsid relationships. Thus *Millerosaurus* is an ancestral sauropsid, in part because it has the type of ear structure briefly described above. (In the theropsids, according to Watson, the tympanic membrane was lost for some time during late Palaeozoic times, and in later forms was re-established as a neomorphic structure, not homologous with the tympanic membrane of the sauropsids. This part of his thesis is disputed by some authorities, notably Vaughan in a recent contribution.)

Because of the important situation of the millerosaurs (as *Millerosaurus* and its near relatives may be designated) in time and in their taxonomic position, this study throws light on many other reptiles and on the whole subject of reptilian classification. Watson believes that the temporal fenestræ are of secondary importance in determining reptilian relationships. He suggests that the millerosaurs, which are essentially cotylosaurs with lateral temporal fenestræ, might well have been ancestral to the prolacertilian reptiles, to the eosuchians and to the great thecodont–archosaur complex; in short, to sauropsids, which comprise the great majority of reptiles through time. He believes that the evolution of the diadectids may represent an entirely separate reptilian development, parallel to the rise of the procolophonid–millerosaur stem, the true base for the sauropsids.

Watson's conclusions are of broad consequence to students of reptilian evolution, and the accumulating mass of evidence would seem to reinforce these ideas. Since the concept of an early dichotomy of evolving reptiles is of such significance to future work in this field it is perhaps unfortunate that Goodrich's term 'Theropsida' is being continued. This word might well be abandoned in favour of some other name that is less apt to get confused in many minds, and particularly in many typewriters and printing presses, with the long-established taxonomic designation 'Therapsida'. Indeed, though not so serious a case, the term Sauropsida bears too strong a resemblance to Sauropoda for complete comfort. Could we not have two new names for the two primary lines of reptilian evolution?

FILTER FEEDING IN FLAMINGOES

Filter feeding is very rare among the higher vertebrates—among the mammals it occurs only in the whalebone whales, and among the birds in the Anatidae and in some species of a few other families. It reaches its highest development in the flamingoes, in which it has been investigated by Miss Penelope M. Jenkin, who reports her results in a recent memoir*.

There are six species of flamingo according to some authorities, or four, one of which is divided into three sub-species, according to others; they are partitioned between three genera. Flamingoes are widely distributed throughout the warmer regions of both Old and New Worlds, and their distribution is determined by the situation of the salt or alkaline lakes where their food occurs in abundance. They thus congregate near the great deserts of the world, often at high altitudes. When Miss Jenkin was working on the ecology of alkaline lakes during the Percy Sladen Expedition to the Rift Valley Lakes in Kenya she was able to watch two species of flamingo feeding, and established that one of them, *Phoeniconaias minor*, feeds exclusively on minute blue-green algae and diatoms. An extremely fine filter is necessary to separate such minute organisms from the water, and further examination showed that the mesh of the filter mechanism in this species is of the order of only 0·01 mm. across. In the other species, *Phoenicopterus antiquorum*, the filter is much coarser with a mesh of about 0·5 mm. × 1·0 mm., and the food consists of such comparatively large organisms as chironomid larvæ, small molluscs and crustaceans and seeds of lacustrine plants. The two species can therefore feed in the same lake without competing for food.

---

* *Phil. Trans. Roy. Soc.*, B, No. 674, 240, 401 (1957): The Filter Feeding and Food of Flamingoes (Phoenicopteri). By Penelope M. Jenkin. (London, Royal Society, 1957.) 35*s*. 6*d*.

A transverse section of the bill of a flamingo shows a median ridge in the roof of the mouth that causes the palate to be V-shaped in section, with each limb of the V opposing the corresponding inner surface of the mandible. In some species, the "shallow keeled" forms, the angle of the V is obtuse; in others, the "deep keeled" forms, it is acute and the opposing surfaces are comparatively much larger. Beneath the apex of the V the tongue, more or less circular in section, fills a corresponding groove between the rami of the mandible. Two rows of recurved hooks on its dorsal surface fit into the spaces on each side between maxilla and mandible. The opposing surfaces of the jaws are beset with rows of lamellæ broken up into small platelets, which in some species have fringed edges so that they show a remarkable resemblance to the baleen of whalebone whales on a minute scale. At the margins of the jaws there is a series of much larger lamellæ or hooks, "the excluders", each corresponding to several rows of the finer lamellæ.

All species of flamingo wade or swim in the water and depress the head into such a position that the upper surface of the upper jaw is directed downwards, a posture which is facilitated by the downward curvature of the distal part of the bill. The head is swept from side to side in wide curves either at the surface or below it according to the species and the type of food sought. At the same time the fleshy tongue is moved to and fro in its groove like a piston so that water is pumped in and out of the mouth. On the suction stroke the jaws are slightly separated to break the filter and allow particles of a size that can pass the excluders to enter the mouth with the water. On the exhaust stroke the jaws are approximated so that the particles are retained on the filter as the water is expelled through it. On the following suction stroke the particles are removed from the filter and passed backwards towards the œsophagus by the recurved spines on the surface of the tongue. The movement of the bill produces an action analogous to that of woolcarders, so that the enmeshed particles are gathered together and presented to the hooks on the tongue.

Flamingoes are not, as has been claimed, monophagous. They eat any organisms that pass the excluders and are retained by the filters, and if the diet is limited to one species that is an ecological accident. When as a result of 'over fishing' or of climatic factors all the organisms that can be collected have disappeared, the flamingoes move to new feeding grounds—they are notoriously erratic in their appearances and breeding sites. But if the normal food supply runs short when they cannot depart because they are tied to a particular area where they are nesting they resort to feeding upon mud, and obtain their nourishment from the organic matter, diatoms and debris, included in it.

Miss Jenkins emphasizes the importance of filter feeding to flamingoes feeding in lakes where the waters differ osmotically and in ionic balance from the body fluids of the birds. By concentrating the food organisms a minimum of the physiologically unsuitable medium is ingested, with a consequent easing of the burden placed upon the kidneys. Filter feeding, in addition to its use in obtaining nourishment, appears to have an equally important function in preventing excess salts from passing beyond the bill into the alimentary canal. In support of this conclusion the author adduces the well-known fact that flamingoes periodically leave their feeding grounds to drink at fresh-water sources.

Finally, Miss Jenkin discusses the affinities and evolution of the flamingoes, and concludes that they are descended from early anseriiform ancestors and that they occupy an intermediate position between the Anseriiformes and the Ciconiiformes.

The author is to be congratulated upon a most interesting and important series of researches which have occupied her attention for a considerable time. As ever in original investigation, her results, while recording numerous hitherto unknown facts, raise a considerable number of new problems which, it is to be hoped, she or her pupils will have the opportunity of resolving. L. Harrison Matthews

THE SITE OF THE NEUROHYPOPHYSIAL OSMORECEPTORS

Through the classical work of Verney in the 1940's, presented so elegantly in his Croonian lecture (*Proc. Roy. Soc.*, B, 135, 25; 1947), a physiological mechanism was elucidated by which the organism is able to regulate its water loss with the urine. A series of elegant experiments accomplished under fully physiological conditions in the dog led Verney to the conception of osmoreceptors situated in the brain, within the distribution area of the internal carotid artery. These receptors, when activated by a normal or raised osmotic pressure of the blood, send impulses to the neurohypophysis to release the antidiuretic hormone.

Recently, P. A. Jewell and Prof. E. B. Verney, in an extensive paper*, have summarized ten years continued work in this field. In a long series of laborious experiments, performed with the utmost carefulness, skill and inventiveness, they have been able to show that neurohypophysial osmoreceptors are localized within the anterior hypothalamus and, perhaps, also within adjacent parts of the pre-optic area. What makes this work so valuable and decisive is the fact that here as in Verney's earlier experiments they have exclusively used blood-borne, physiological stimuli on unanæsthetized animals.

It is not possible to do justice to this work within the limits of a short review, but some of the main points may be mentioned.

To trace the arterial blood, which in the different experiments had carried the osmotic stimuli, it was first necessary to make a careful anatomical study of the arterial connexions of the circle of Willis and of the detailed vascular architecture of the diencephalon and the hypophysis in the dog, and further, with the help of suitable coloured substances, to study the distribution of vertebral and carotid blood in the brain. These careful studies of the vascular supply of the dog's brain will certainly be of the greatest value to anyone who, in the future, traces the distribution of arterially injected substances in the brain of the dog.

---

* *Phil. Trans. Roy. Soc.*, B, No. 672, 240, 197 (1957): An Experimental Attempt to Determine the Site of the Neurohypophysial Osmoreceptors in the Dog. By P. A. Jewell and Prof. E. B. Verney. (London: Royal Society, 1957.) 53s. 6d.

After an account of these preliminary studies, the authors describe experiments performed to localize the osmoreceptors. Having tested the antidiuretic response obtained from infusions of hypertonic saline into the common carotids in dogs supplied with carotid loops but otherwise intact, they started to study the effect of tying one or more of the carotid branches supplying the brain with blood. Tying of the branches of the internal carotid intradurally, especially, necessitated a very delicate operative technique. After killing the animals, the distribution areas of both carotids were traced with the help of coloured substances. In all cases where an antidiuretic response to infusions of hypertonic saline was obtained on the side of the brain where the distribution of carotid blood had been restricted, the anterior hypothalamus and adjacent parts of the pre-optic area had been reached by hypertonic blood. No other part of the brain was reached directly by the infusions. The authors thus have good reason to conclude that the neurohypophysial osmoreceptors are localized in the anterior hypothalamus and perhaps also parts of the pre-optic area.

The results of the last two experiments reported in the work might at first sight seem somewhat confusing. In these, all three main branches of the internal carotid had been tied intradurally on one side, leaving some smaller branches to supply the ipsilateral parts of the hypothalamus with arterial blood. The result in both cases was that the antidiuretic response seen before the operation, due to intracarotid infusions of hypertonic saline, vanished completely. The occlusion of these three branches of the internal carotid had, however, in one of the dogs, caused the formation of a cyst in the anterior hypothalamus, and a reduction in the number of cells in the remaining nuclei. In the other dog a large cyst was formed in the thalamus, and the greater part of the anterior hypothalamus had been supplied from the carotid of the opposite side. This seems in itself to be a possible explanation for the lack of response to the infusion of hypertonic saline on the side operated upon.

On the basis of these two experiments, and of other observations which cannot be mentioned here, the authors put forward the interesting hypothesis that the functioning of the hypothalamic osmoreceptors may be dependent upon the integrity of nervous connexions with the thalamic paraventricular nucleus. Further experiments to test the validity of this hypothesis are suggested at the end of the paper.

In short, this solid work of Jewell and Verney forms an extremely valuable complement to Verney's earlier pioneering research on the physiological regulation of the function of the neurohypophysis. Their results have meanwhile been fully supported by the work carried out at the Royal Veterinary College of Stockholm by B. Andersson and his collaborators, who have been able to elicit not only thirst, but also an inhibition of water diuresis in conscious goats, by electrical stimulation within the anterior hypothalamus.

Yngve Zotterman

MOSAIC EVOLUTION IN HYDROIDS

In many animals different organs are capable of undergoing independent evolution at different rates. The idea of 'mosaic evolution' is becoming familiar to systematists in a number of groups. It both enriches the story of phylogeny, and bedevils those classifications that have relied on a few 'good taxonomic characters'. In the hydroid coelenterates, moreover, the two phases of the life-history—polype and medusa—have an almost independent existence, and it is peculiarly easy for them to evolve separately and each acquire new characters not apparent in the morphology of the other. In traditional classifications, the polype and medusa of the same species have often had different names, separate families and have been described by different workers. Realization of this was not wanting, even in 1864 with Allmann's lament that "the principles of classification that have been regarded as the only sound ones in other groups have been almost entirely ignored in our attempts at a systematic arrangement of the Hydroida".

With modern knowledge the need for dual classification is ending, and in a recent report* by Dr. W. J. Rees, proposing a new arrangement of the capitate hydroids, a large advance has been made. Dr. Rees has, for the first time, merged polypes and medusæ into a single phylogenetic classification; and in this he has had much careful work to draw upon, especially the studies of Russell, Kramp and himself. This must be an important paper for the hydroid specialist; and it is a stimulating one for the general zoologist who is fond of hydroids or teaches marine biology. The author gives a lucid account of the suborder Capitata, drawing his evidence widely from both polype and medusa, with particular attention to the relation of form and function in his own experience of living hydroids. The resulting classification is a 'liberal' and broad-based one.

Theories of alternation of generations (there seems no good reason to avoid this term) are reviewed. The older hydroid theory held the sexually propagating polype to be the primary form in Hydrozoa. The medusa arose from a later 'division of labour', though this hypothesis could never properly account for the Trachylina. Dr. Rees firmly supports Brooks's theory (now most widely accepted) of the ancestral role of the simple 'actinula', which gradually took advantage of attachment, and by vegetative proliferation gave rise to a polypoid phase. The earliest hydroid was probably a primitive medusa, comparable with a trachylinid, and the medusal theory and actinula theory are in fact complementary.

The body of the paper is a consideration of evolutionary trends and mosaic patterns developed in the polype and the medusa. Dr. Rees rejects Kramp's view that the colonial corynoids are the most primitive polypes: colonial forms—he holds—have arisen from solitary forms, and the existing lower Corymorphines come nearest to the ancestral form of the hydroid polype. Here we have types like *Hypolytus* and *Euphysa* with a feeble perisarc, no diaphragm and no well-developed stem canals. The oral tentacles are capitate or moniliform but the aboral circlet always moniliform, corresponding with the tentacles of the early medusa. In these lower polypes they form the long fishing tentacles suited to life on a muddy substrate. Capitate tentacles arose later. Polypes have evolved along three broad lines. In the *Corymorpha–Tubularia–Margelopsis* line, we find the largest and most elaborate polypes, the Tubulariidae acquiring a firm perisarc and settling on hard substrata, and the margelopsid polypes becoming specialized and pelagic. The larger polypes of this line develop a most complex internal structure; *Corymorpha nutans* is 11·4 cm. in length, *Brachiocerianthus imperator* a giant of 224 cm. In the second or *Acaulis–Myriothela* line, starting with the primitive *Acaulis*, the polypes become vermiform, with short capitate tentacles scattered over the intertentacular area. *Myriothela austrogeorgiae* reaches 30 cm. in length. The third series—the corynoids—have become colonial, with the individual polypes much smaller, and the aboral tentacles lost, as in the "deceptively simple polypes of the Corynidae". Food circulates from polype to polype by a continuous coenosarc, and in the higher corynoid family, the Zancleidae, Russell and Rees have found sexual and nutritive differentiation among the polypes (elsewhere much more emphasized among Hydroida).

* Bulletin of the British Museum (Natural History). Zoology. Vol. 4, No. 9: Evolutionary Trends in the Classification of Capitate Hydroids and Medusae. By Dr. William J. Rees. Pp. 453–534 + plates 12 and 13. (London: British Museum (Natural History), 1957.) 25s.

The position of the gonophores, egg size and encystment and evolution of the perisac are considered, followed by a survey of evolution in the medusae. Dr. Rees regards the medusae of capitate hydroids (the Codonidae of Haeckel) as the most primitive of all. The ancestral form—not unlike a modern *Sarsia*—had a deep bell-shaped umbrella with scattered nematocysts, four per-radial tentacles with moniliform nematocyst batteries, four radial canals, a ring canal and a ring gonad surrounding the stomach. Moniliform tentacles are retained in many corymorphine polypes, but only *Euphysa* has them in both polype and medusa.

Dr. Rees agrees with Broch and Kramp that the condition of the gonophore—an attached sporosac or a free medusa—is by itself of little taxonomic value. But the free medusa has much higher claims: it is not so much an organ only a little removed from a fixed eumedusoid, but an independent organism undergoing its own evolution. Its morphology, duration of life and reproductive behaviour carry great weight in discrimination of species, genera and even families. Many species find "fuller opportunity for expression in a free planktonic phase than in a sedentary benthic phase".

Phyletic lines of polypes and medusae are summarized in two schematic figures (57, 58). Generalized though these must be, they might have been even more helpful to the non-expert if they could have been given fuller captions. Dr. Rees's classification introduces four superfamilies into the suborder Capitata of order Anthomedusae. The Tubularoidea contains the Corymorphidae, Tubulariidae and Margelopsidae; the Tricycluisoidea is set up for the unique species *Tricyclusa singularis*. The Acauloidea includes the Acaulidae and Myriothelidae; and in the Corynoidea are grouped ten colonial families with simple hydranths centring around the Corynidae. For some of these, such as the Cladocorynidae and Asyncorynidae, this grouping is provisional and common ancestry is not claimed. J. E. Morton

HOW DOES THE EHRLICH ASCITES TUMOUR OBTAIN ITS ENERGY FOR GROWTH?

By A. KEMP and Prof. B. MENDEL, F.R.S.

Pharmaco-therapeutic Laboratory, University of Amsterdam

In the peritoneal cavity of the mouse, cells of the Ehrlich ascites tumour multiply rapidly. After transplantation their number increases about 25-fold within five or six days. This growth is accompanied by a corresponding increase of ascitic fluid.

Since the ascitic fluid contains only traces of glucose and oxygen[1], it seems surprising that the cells can grow in this medium. In the course of recent experiments *in vitro*, Warburg[2] "placed varying amounts of energy at the disposal" of the ascites cells and then transplanted them. He observed that the cells died when neither glucose nor oxygen was supplied for twenty-four hours, but that "one-fifth of their growth energy" was sufficient to preserve transplantability. Though these experiments seem to show that ascites cancer cells can survive under conditions of near-starvation, the question still remains as to how they find the energy for *growth* in the ascitic fluid.

Glucose Concentration and Glycolysis

It is well known from Warburg's experiments with surviving tumour slices that a glucose concentration of about 200 mgm./100 ml. is required for maximum glycolysis. At glucose concentrations lower than 80 mgm./100 ml. the rate of glycolysis decreases sharply, amounting to less than one-fifth of its maximum at a glucose-level of 5 mgm./100 ml. A similar relation between glucose concentration and fermentation has been found with cell suspensions, for example, with yeast cells. Here, too, the rate of fermentation diminishes considerably once the glucose concentration has dropped below 200 mgm./100 ml.

When we became interested in the metabolism of the ascites tumour cells *in vivo*, we first inquired into their glycolysis in relation to the glucose concentration in the medium. This seemed necessary in view of the extremely low level of glucose in the ascitic fluid. We found that, *in vitro*, the maximum rate of glycolysis is still maintained at a glucose concentration as low as 4 mgm./100 ml. Once the level of glucose has fallen off to about 3 mgm./100 ml.; glycolysis ceases abruptly. Ehrlich ascites tumour cells would thus be able to make full use of their glycolysing capacity, if the ascitic fluid were to contain a minimum of about 4 mgm./100 ml. of glucose.

Concentration of Glucose in the Ascitic Fluid

As far as we have been able to ascertain, the concentration of glucose in the ascitic fluid has not yet been accurately determined. Since the amounts of glucose present in the fluid are too small to be estimated quantitatively by the usual methods, we adopted the following procedure. Immediately after the withdrawal, the ascitic fluid was mixed with 4 volumes of ethanol, centrifuged and the supernatant fluid evaporated under reduced pressure. The residue was suspended in 5 per cent trichloro-acetic acid so as to bring it to the original volume of the ascitic fluid. After adding 1 mgm. of charcoal per ml., the suspension was centrifuged. The glucose concentration in the clear supernatant fluid was then determined colorimetrically with the aid of the anthron–sulphuric acid reagent. Irrespective of the age of the transplant 5–7 mgm./100 ml. of glucose were found, a concentration at which glycolysis of the tumour cells is at its maximum.

Source of the Glucose

From measurements of the metabolism of ascites tumour cells *in vitro*, Warburg and Hiepler[1] have calculated how much glucose the cancer cells, present in 5 ml. ascitic fluid, would glycolyse if they used their glycolysing capacity to the full: under anaerobic conditions they could glycolyse about 44 mgm. of glucose per hour and under aerobic conditions half that amount. As we have seen that the glucose concentration in the ascitic fluid is above the optimum for the glycolysis of the cancer cells, it can be inferred that the influx of glucose is adequate. Nevertheless, we have also attempted to assess experimentally the rate of influx of glucose into the ascitic fluid. Normal mice were injected intraperitoneally with 5 ml. of ascitic fluid made cell-free by centrifugation. This fluid contained 3 mgm./100 ml. of glucose. When it was withdrawn 3 min. after the injection, the glucose concentration had risen to 17 mgm./100 ml. Thus, 14 mgm. of glucose could diffuse into 5 ml. of ascitic fluid within one hour. This amount would not fully meet the requirements of the cancer cells for maximum glycolysis under aerobic conditions. However, one important factor had to be omitted from our experiment, namely, the ascites tumour. The tumour cells keep the glucose-level low in the surrounding medium and thus enhance the flow of glucose through the capillary walls into the ascitic fluid. Conversely, in the cell-free ascitic fluid with its rising glucose concentration, the influx of glucose will progressively slow down. For this reason we chose the shortest possible interval of time, namely, 3 min., to determine the rate of influx. Even at the end of so short a period, however, the glucose had already risen to a higher level than is found at any time in the ascitic fluid of a mouse bearing the ascites tumour. If we make allowance for this unfavourable factor in our experiment, it would appear that the amount of glucose which diffuses into the ascitic fluid is large enough to keep the cancer cells saturated under aerobic conditions.

At first sight it seems surprising that such large quantities of glucose should be available in a mouse. Its blood and liver together contain less than 50 mgm. of carbohydrate, while more than 500 mgm. of glucose is consumed in twenty-four hours by the cancer cells present in 5 ml. of ascitic fluid. Where does all the glucose come from?

In the ascitic fluid of a tumour-bearing mouse the lactic acid concentration is maintained at a level of about 100–150 mgm./100 ml. by the glycolysing cancer cells. We have followed the absorption of the lactic acid by injecting 5 ml. of cell-free ascitic fluid intraperitoneally into normal mice. Ten minutes after the injection the concentration of lactic acid in the ascitic fluid had on the average dropped by 44 mgm./100 ml. Thus, at least 13 mgm. of lactic acid could be absorbed from 5 ml. ascitic fluid within one hour. Some of the lactic acid might be oxidized by the cancer cells; the major portion, however, will be absorbed into the blood-stream and transformed by the liver into glycogen, which, in its turn, will replenish the blood with glucose. In this way, the greater part of the glucose, glycolysed by the cancer cells, will re-enter the ascitic fluid and once more be available for glycolysis. Thus it appears that in spite of the very great consumption and the low concentration of glucose in the ascitic fluid, ascites tumour cells, no less than other cancer cells, are able to derive a major part of their energy for growth from glycolysis.

We are indebted to Dr. G. Klein, Stockholm, for supplying us with the Ehrlich ascites tumour. A detailed account of our experiments will appear elsewhere.

SEISMIC RECORDINGS OF ATOMIC EXPLOSIONS IN AUSTRALIA

By H. A. DOYLE

Department of Geophysics, Australian National University, Canberra

DURING September and October 1956 four atomic weapons were exploded in South Australia. At the suggestion of Sir Edward Bullard, and with the co-operation of the British Atomic Weapons Research Establishment, the ground waves produced by these blasts were recorded at seven different localities, mainly near stations on the Trans-Australian railway. This unusually long and straight railway passes through the desert of the Nullarbor Plain and so provides a useful traverse of low noise-level along which to record seismic waves from the weapon trials area at Maralinga, which is situated towards the eastern end of the line (Fig. 1). The geology of this plain may be simply described as horizontally bedded Miocene limestone, known to be 900 ft. thick in places, with the Yilgarn Pre-Cambrian Shield to the west and possibly underneath the limestones. The three most distant stations were on the Yilgarn Shield.

An attempt was made to record at roughly 2° intervals to as great a distance as possible. Records were obtained out to a distance of 10·7°, and it may be possible to extend this distance in future recordings.

At six of the stations, instruments of high gain and fast paper-speed were used, and at the other a Willmore seismograph. The former instruments, which were built by Dr. P. G. Gane for similar work in South Africa, consisted of a vertical and a horizontal

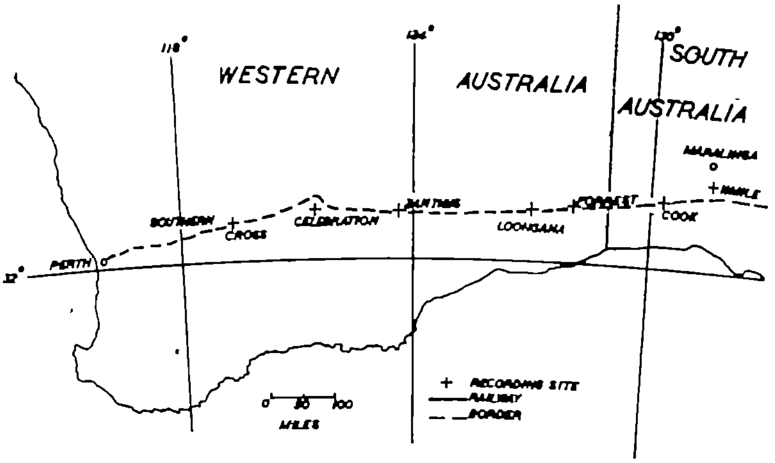

Fig. 1. Location of stations

geophone (orientated longitudinally) with natural periods about 0·6 sec., two amplifiers and a three-galvanometer recorder of paper-speed about 2 cm./sec.

Time-marking was provided by chronometers together with recording of W.W.V. radio time-signals on one of the galvanometers. Arrival-times could be read to 0·1 sec. quite easily on the records of the fast recorders, and to 0·5 sec. on the Willmore record.

The times of the explosions and their geographical co-ordinates were supplied by the Atomic Weapons Research Establishment. All four explosions were used, but only one explosion was recorded at each station. The positions of the recording sites were calculated from railway survey data and State Lands Department maps. Geocentric distances were then calculated using the formula 2 vers $\Delta = (a - A)^2 + (b - B)^2 + (c - C)^2$. The standard error of the distances so obtained[1] is 0·6 km. Height and ellipticity corrections of the observed times were not applied, being less than 0·1 sec.

Only phases that are easily discerned in the records are reported in this communication. As can be seen from inspection of Fig. 2, most phases lie close to one of four straight travel-time curves. Two of these were interpreted as P_n and S_n. The others were designated P_1 and S_1 and are discussed below. With the exception of P_1, the times were fitted to linear t—Δ relations by the method of least squares.

P waves. The P_1 phase was recorded as the first arrival at the closest two stations, as the second arrival at Forrest (3·18°) and possibly as a later arrival at Loongana (4·11°).

Owing to uncertainty in measuring the travel-time to the closest station, only the Cook and Forrest results were used to calculate the P_1 velocity. The resultant value of 6·12 km./sec. with a time intercept of 0·2 sec. indicates that P_1 is apparently the P-wave velocity immediately below the sediments.

The second velocity, 8·23 ± 0·02 km./sec., was calculated from the four first arrivals from Forrest to Celebration and was taken to be P_n. This value was calculated using the mean earth radius 6,371 km., so that the result is directly comparable with that of other investigators. Use of the radius to the Mohorovičić discontinuity will lower this velocity by approximately 0·05 km./sec. The second arrival at Cook also lies close to the P_n curve, but may be a reflexion from the Mohorovičić discontinuity. The standard deviation of the residuals from a linear relationship was 0·12 sec., compared with Willmore's value[2] of 0·19 sec. for the Heligoland experiment. The small residuals show that the P_n curve is close to linearity, out to 8·7°. Since the records were obtained in only one direction, this velocity could have a systematic error due to dip of the Mohorovičić discontinuity. At the outermost station, Southern Cross (10·7°), the residual obtained by extrapolating the 8·23 km./sec. curve to this distance is −1·9 sec. This large residual is evidence of a possible bend in the P_n travel-time curve between 8·7° and 10·7° due to an increase of velocity with depth.

Our P_n and S_n travel-times were respectively 6 and 14 sec. earlier than those given in the Jeffreys–Bullen tables for 10°. Other possible P-phases are shown in Fig. 2, but these do not indicate any additional layers.

S waves. At most stations two later arrivals were recorded, usually with slightly larger amplitudes and longer periods (0·1–0·2 sec.). The arrival-times were fitted to two straight travel-time curves, giving velocities of 4·75 ± 0·02 km./sec. (using the mean earth radius), and 3·56 ± 0·03 km./sec. These waves were interpreted as S_n and S_1.

Except for Southern Cross, where the noise-level was high at the time, S_1 was recorded at all stations, in contrast to P_1 which was observed only as far as Loongana (4·1°). The greater range of S_1 is possibly due to conversion to the surface wave L_g with increasing distance, as suggested by Press and Ewing[3].

Bullen[4] found evidence for the occurrence of a prominent S-phase in New Zealand records of near earthquakes, and Bullen and Bolt[5] found similar evidence in records of a South Australian earthquake. This phase had an estimated velocity of 3·7 km./sec., and was designated S^*. P^* was thought to be less prominent and P_g and S_g doubtful. It is therefore suggested that our P_1 and S_1 correspond to the P^* and S^* of earlier analyses of near earthquakes.

The P_n and S_n time intercepts were 7·56 and 14·76 sec. respectively. Assuming a uniform 'crust'

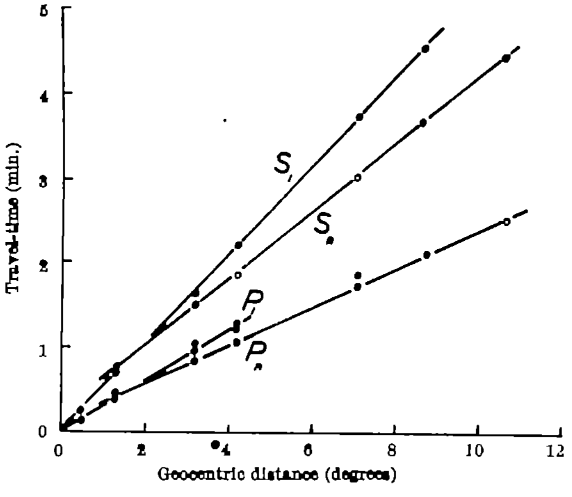

Fig. 2. Travel-time curves

in which the velocities are these P_1 and S_1 velocities, the depth to the discontinuity was formally estimated as 35 ± 2 km. using the P-wave data, and 40 ± 2 km. using the S-wave data.

The results of this survey are similar to those obtained by recording explosions in certain other continental regions; for example, P_n velocities which have been measured are: North Germany[2], 8·18 km./sec.; Western Transvaal[3], 8·27 km./sec.; Canadian Shield[7], 7·91–8·21 km./sec.; United States[8], 8·1 km./sec.; Wisconsin[9], United States, 8·17 km./sec.; Pennsylvania[10] and New York, United States, 8·14 km./sec.

This work was made possible by the co-operation of the Atomic Weapons Research Establishment, the Australian Department of Supply and the Commonwealth Railways. Instruments were generously loaned by the Bernard Price Institute, the Pakistan Meteorological Service, the Scripps Institution of Oceanography and the Hydrographic Branch of the Royal Australian Navy. The Royal Society provided a grant towards transport of the instruments.

Acknowledgment is also due to Prof. J. C. Jaeger, who supervised the project, and to the advice of Prof. K. E. Bullen and Dr. G. de Q. Robin.

A GENERAL THEORY OF MEMBRANE TRANSPORT FROM STUDIES OF BACTERIA

By DR. PETER MITCHELL

Department of Zoology, University of Edinburgh

IT has recently become evident that the basic problem of membrane-transport (even in the cases of sodium and potassium ions) is concerned with the movement of chemical groups through the membrane[1,2]. In this article I shall therefore consider the problem of membrane-transport in terms of the relationship between 'biochemical' group-transfer reactions[3] and 'biophysical' membrane-transport reactions, breaking with the tradition that has allowed the extensive studies of electrolyte movement complicated by bioelectric potentials to dominate the field of membrane-transport. The work that I shall describe will suggest a general theory[4] which might be restricted to bacteria, but for reasons that will become obvious, it is more likely that the mechanisms of membrane-transport will show the same general uniformity in different genera as do those of metabolism.

Some years ago, I suggested[5] that the internal concentration of free glutamic acid in streptococci is determined by three rate processes: (1) the rate of active transport inwards, dependent upon glucose metabolism; (2) the rate of entry into the 'metabolic pool'; (3) the rate of diffusion out through the membrane. This suggestion was verified by the use of inhibitors and accelerators specific for one or other of the three processes[6].

Later work on amino-acid accumulation and protein synthesis in cocci and *Bacterium coli* led away from the above membrane-transport explanation[7,8]. A more 'biochemical' interpretation was placed upon amino-acid accumulation, the free internal amino-acids being assumed to exist as activated or labile compounds, and the plasma-membrane being considered to be permeable to all amino-acids[9]. Recently, however, the pool of free internal solutes and the membrane that separates this pool from the external medium have been demonstrated in my laboratory by unequivocal permeability and osmotic pressure measurements[10,11]. These observations have received support from Dr. E. F. Gale's laboratory[12] and from elsewhere[13-15].

With the return to favour of the membrane-transport view of the accumulation of certain amino-acids, two facts which accorded with the more 'biochemical' interpretation have, however, still to be explained: first, the entry of these amino-acids into internal protein and external peptides without passage through the internal free amino-acid pool[6]; and second, the rapid exchange of certain analogous amino-acids (for example, valine and *iso*leucine) with one another across the membrane[15]. I shall return to these facts later.

It has been shown by the use of tracers that the plasma-membrane of resting staphylococci prevents a net flow of phosphate, but permits a quite rapid strictly reciprocal exchange between the inorganic phosphate molecules on either side. When, however, the cells respire in glucose, the flow of phosphate inwards remains unchanged, but the outflow approaches zero; so that phosphate is transported inwards. These and other facts led to the conclusion that the same translocation mechanism operates in the exchange and uptake, and that one may analyse the translocation process of active transport by studying the exchange reaction in resting cells[16,17]. Kinetic studies indicated that the rate of the phosphate-exchange reaction is proportional to the degree of saturation of an externally accessible reactant with $H_2PO_4^-$, just as the rate of an enzyme-catalysed reaction is proportional to the degree of saturation of the enzyme with its substrate. Moreover, the reactant in the plasma-membrane displays enzymic specificity towards the $H_2PO_4^-$, and the exchange reaction is susceptible to specific inhibitors all of which also inhibit the active transport[11]. Only arsenate can be substituted effectively for phosphate, the exchange of arsenate for phosphate across the membrane being as strictly coupled as that of phosphate for phosphate. The transport of arsenate can consequently be driven against a concentration gradient by the reverse movement of phosphate in resting cells.

The observations on the phosphate-exchange system could be explained by invoking a mechanism similar to the exchange-diffusion mechanism proposed by Ussing[16] to account for the exchange of sodium. He suggested that the ions saturate a carrier on which they may pass through a membrane which they cannot traverse in the free state. The phosphate-exchange system differs from Ussing's model, however, in a most important respect. Ussing[8] pointed out that when the carrier of his system is unsaturated on one side of the membrane, a net flow of substrate will occur. The K_m (0·8 mM) of the phosphate exchange would represent the dissociation constant of the carrier in Ussing's model; yet, even when the external $H_2PO_4^-$ concentration was lowered to 0·1 mM, there was no significant flow of the internal 100 mM inorganic phosphate outwards. The simplest explanation that I have been able to suggest to account for the strictness of the coupling in this system is as follows: phosphorylated carriers are present in the membrane, the phosphoryl groups of which, due to thermal movements, become alternately accessible to the media on either side where a specific exchange may occur between the phosphoryl groups on the carriers and phosphate ions without loss of the bond-energy of the carrier-phosphoryl compound[16]. In this system the carrier-ion compound (or complex) is not in equilibrium with its hydrolysis (or dissociation) products as it is in Ussing's system. The explanation that I have suggested amounts to making a strict analogy between the translocator and the combining centre of a group-transferring enzyme; for group-transferring enzymes are known to form intermediate covalent compounds with the group that they transfer from one substrate to another[9,19].

Gourley's observation[20] that phosphate may be carried through the membrane of erythrocytes as adenosine triphosphate led to the suggestion that the phosphate-exchange system of staphylococci might operate with adenosine triphosphate as the carrier and phosphokinases as the enzymes catalysing the exchange. But I pointed out that if this were so, the strongly lipophobic properties of adenosine triphosphate would almost certainly have to be masked by some large molecule such as a protein of low solubility in water in company with which it would have to pass across the osmotic barrier by a translational or rotational movement of the large molecule[16]. This is a quite different conception from Goldacre's theory, supported by Danielli[21], that contractile enzymes cause active transport by forcing the solute mechanically through the membrane. According to Prankerd[22], phosphate uptake in erythrocytes may be enzymically linked to the conversion of 3-glyceraldehyde phosphate to 1,3-diphosphoglycerate close to the cell surface; but while perhaps implying direct participation of glyceraldehyde-3 phosphate dehydrogenase, he states that "enzymes do not necessarily play any intimate role in the actual movement of any substance". In contrast to this, the view that I am stressing here is that the oxido-reduction and group-transferring enzymes of classical biochemistry do in fact catalyse (but do not force) the movement of a chemical group from one substrate (or coenzyme) to another on or within the enzyme molecule. It is therefore logical to consider[23] that the catalysts of translocation may be proteins identical to normal enzymes, the translocation being a normal enzymic attribute when the enzyme forms part of the membrane[10,11]. It is, of course, conceivable that protein catalysts of translocation may lack chemical catalytic function. In either case the name 'translocase' might aptly be used, although in the former the normal biochemical name of the enzyme concerned might be quite sufficient. The molecular group covalently linked to the substrate during translocation—which may be a small molecule such as a lipid or nucleotide, or may be the combining centre of a translocase—will be called the 'translocator'. The characteristics of the phosphate-exchange reaction are summarized diagrammatically in the right side of Fig. 1. The ringed P represents phosphoryl as HPO_3^-; the black area, the 'translocator'; and the shaded area, the translocase. Although the translocator has been depicted as moving bodily in the membrane, it might alternatively be so placed in relation to the translocase as to be accessible to its substrate from either side without itself undergoing a strictly molecular movement, but rather an electronic one.

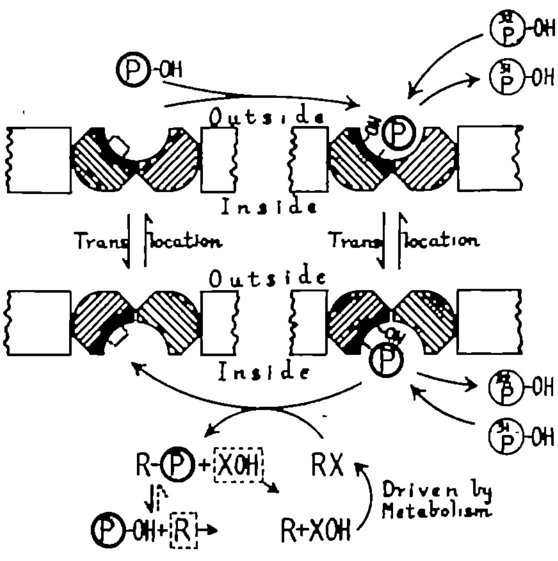

Fig. 1

During respiration in glucose, phosphate is actively transported inwards by a process which inhibits the outward passage of phosphate but not the outward movement of the carrier. This may be caused by the occupation of the translocator during its outward movement by another substrate or by an internal bond. A mechanism of the latter type is illustrated in Fig. 1; and in a corresponding substrate-exchange-type mechanism, the group X of the hydrolysable intermediate of carbohydrate metabolism, R–X, would travel out in exchange for phosphate.

Observations on the movement of glucose, galactose, lactate, pyruvate, succinate, malate and fumarate through the membranes of cocci and *Bact. coli* by direct permeability measurements have shown that the plasma-membrane of resting cells does not permit a significant net flow of these solutes; and kinetic, metabolic and inhibitor studies indicate that the mechanism of entry of these substrates is closely similar to that of phosphate[10,11,24]. Genetic and kinetic observations on the uptake of amino-acids[18,25], sugars[14] and citric acid[26] by bacteria may be similarly interpreted.

An enzymically controlled mechanism of active transport would require the presence of enzymes in the plasma-membrane. While we have not yet been able to demonstrate particular components involved in membrane-transport, it has nevertheless been possible to show that the plasma-membrane of staphylococci is a complex lipo-protein sheet about 50 A. thick, containing about 20 per cent lipid and 40 per cent protein exhibiting many oxidative and hydrolytic enzyme activities, and including some 90 per cent of the total succinic, lactic and formic dehydrogenases and the bulk of the cytochrome of the cell[27]. A similar enzymic composition has recently been described for the plasma-membrane of *Bacillus megaterium*[28].

The object of this article is to suggest—as a logical extension of our previous hypothesis that enzymes are the conductors of bacterial membrane-transport[11]—that metabolic energy is generally converted to osmotic work by the formation and opening of covalent links between translocators in the membrane and the carried molecules exactly as in enzyme-catalysed group-transfer reactions. The translocation itself is supposed to be due either to a thermal movement of the translocator in the membrane, or to the simultaneous accessibility of the translocator from both sides; and this movement or availability may be determined by a normal enzyme (or perhaps by a special protein), which we may call a translocase. The efficiency of the osmotic process could thus be equivalent to that of classical group-transfer reactions. I have described elsewhere how a reaction of this type may drive the movement of ions such as sodium and potassium which are supposed not to form covalent bonds[4].

The displacement of analogues that occurs during accumulation of amino-acids[13] and also of sugars[14] cannot, as Cohen and Rickenberg have pointed out, be adequately explained by the quantitative counterpart of the kinetic scheme described above for glutamic acid transport, in connexion with which they and Buttin and Monod have introduced the term 'permease'. It can, however, be explained by the type of system that I am now proposing, since exchange-translocation may occur in the active transport channel with any pair of substrates that can both use the translocator. Reactions 1 and 2 of the scheme described above are more closely linked than was at first suspected, and reaction 3 may be negligibly slow under normal conditions.

The fact that external amino-acids may form internal protein or external peptides without entering the free amino-acid pool would be explained by the uptake of the amino-acids into the membrane as covalent translocator (that is, activated) compounds. Further, the synthesis of the polypeptides and polysaccharides[29] of the cell-wall outside the plasma-membrane may be similarly explained.

The active transport may be driven by covalently bound metabolic end-products such as carbonic or other organic acids[19] which pass outwards on the translocators and are exchanged for nutrients at the outer surface of the membrane. Alternatively the translocators may have internal bonds, such, for example, as the diphosphopyridine nucleotide-thiol bond of glyceraldehyde-3-phosphate dehydrogenase[30] or the —S—S— form of lipoic acid[31], which may be opened by the entry of the reactant approaching from outside the membrane and closed again by coupling with oxido-reductions when in contact with the inner medium.

Such a close linkage of membrane-transport with metabolism would explain the long-standing anomaly[32] of the low physical permeability of cell membranes and the comparatively easy accessibility of the metabolic systems to the nutrients of the medium.

In view of the facts discussed in this article, I suggest that, since it has not yet been strictly defined, the word 'permease' (by analogy with hydrolase) should be reserved to describe protein catalysts of facilitated permeation or diffusion which might, for example, play the part of the hydrolytic or dissociation-type carrier of Ussing's exchange-diffusion system. If a word outside the normal nomenclature of enzymes should be desirable to describe the type of translocation catalyst considered here, it would be appropriate to use the term 'translocase' (by analogy with transferase); for the reaction catalysed is the translocation across the membrane of a covalently-bound group which is in equilibrium, not with its hydrolysis or dissociation products (as is the bound group in facilitated permeation or diffusion), but with the metabolic intermediates that give rise to the active transport.

I am indebted to many colleagues for valuable discussion, criticism and encouragement, especially to Prof. J. F. Danielli, Miss J. Moyle, Dr. J. M. Mitchison and to the head of this Department, Prof. M. M. Swann. It is also a pleasure to acknowledge support by grants from the Scottish Hospital Endowments Research Trust.

The Units of Time and Length

SINCE the atomic standard of frequency was put into operation[1], a number of comments have been published[2–10] concerning the possibility of using the standard to define the unit of time; but two queries initially raised by Dr. G. M. Clemence[2] have not yet been fully answered.

The discussion has been somewhat obscured by the fact that some contributors regard units as abstract ideas which are invariable, and others as the practical realization of these ideas which are not invariable. All physical measurements are made in terms of the practical units, and the concept of ideal invariable units does not seem to be necessary although some physicists have found it useful. It is certainly confusing when the same name is used for both the ideal and the practical units, and in my view it is preferable to restrict the term 'unit' to those practical quantities in terms of which the results of measurements are expressed. They are chosen so that they can be regarded as constant for most purposes, which is indeed essential if they are to serve as the foundation of a reliable structure of physical measurement. But if the precision of measuring a quantity in terms of the appropriate unit is equal to or greater than that with which the unit itself can be defined, then the possibility of variations of the unit must be considered.

When this position arises, it often, but not always, means that the quantity which can be measured with the higher precision could be used for defining a more precise unit. For example, variations of the mean solar second have been established by both the atomic standard and by quartz standards; but whereas the atomic standard could be used to define the unit, quartz standards are quite unsuitable for this purpose. In a strictly formal sense, the value of a unit remains constant in that its value is, by definition, taken as unity in quantitative results. Thus as long as the mean solar second was used as the unit of time, the rates of pendulum, quartz and atomic clocks all varied in a periodic manner. The simpler assumption is that the unit is varying, and from the beginning of 1957 a new unit of time, the second of the time-scale U.T.2, has been employed; and if the correction used in deriving this new unit is valid, all these periodic variations will have disappeared. Although, therefore, the second can be regarded as a constant unit of time for almost all purposes, for the most precise measurements its constancy cannot be taken for granted, and it must be carefully labelled if experimental results are to be interpreted correctly.

The consequence of the adoption of atomic units which seems to cause physicists the most concern is the constancy of the velocity of light. This is regarded as a limitation; but a little consideration shows that it is an essential feature of any system of units incorporating the wave-length standard of length. For although the wave-length standard can be defined and used without reference to any physical laws, it is important to consider the laws governing the emission and propagation of electromagnetic waves. The quantum mechanical law of emission can be written:

$$\nu = (E_2 - E_1)/h$$

where ν is the frequency of the radiation, E_2 and E_1 are two energy-levels of the atom and h is Planck's constant; and the law of propagation is simply $v = \lambda\nu$ or, in a vacuum, $c = \lambda\nu$, where λ is the wave-length and c is the velocity of light. As there is no reason to believe that there is a close relationship between the two laws, the wave-length of the radiation is constant only if both ν and c are constant. A self-consistent system of units can therefore be obtained only by choosing the unit of time so as to maintain the constancy of these two quantities. The only way of achieving this is to use ν, the frequency of the radiation, to define the unit of time.

Practical considerations, however, make it inconvenient to adopt this ideal system, because there is at present no technique for measuring the frequency of a light-wave, and the techniques of using radio-waves, the frequencies of which can be measured, for length measurement are not yet sufficiently highly developed. The present choice would therefore be to use a radiation such as that of the cæsium line for defining the unit of time, and the radiation of a suitable light-source for defining the unit of length. The resulting system, which was suggested in principle by Drs. Huntoon and Fano[11] in 1950, is self-consistent so long as the ratio of the frequencies of the two radiations remains constant. The units of length and time are no longer independent in the proposed system, the two independent quantities being the frequency of the emitted radiation and the velocity of light. Of the three quantities concerned, any two can be given arbitrary values in order to define the units of measurement, although, of course, in practice, discontinuities in physical measurements will be avoided by choosing the 'arbitrary' values so as to preserve the existing values of the units within the accuracy with which they are known.

The second point raised by Dr. Clemence[2] is the difficulty of ensuring that two atomic clocks indicate the same time (epoch) and of ensuring continuity of operation. It has already been indicated briefly[7] that quartz clocks and astronomical measurements together can be used for this purpose; but it may be useful to discuss the problem in a little more detail. Quartz clocks directly controlled or monitored by the atomic standard provide a time-scale, in steps of 10^{-8} sec., extending over periods of years, and this scale is adequate for all physical measurements that can be envisaged. In general, only time-interval is required in such measurements, epoch being of no significance. For astronomical measurements and for civil time, it is convenient to define epoch in relation to the position of the Earth relative to the Sun, but the precision required is relatively low and will always be limited by that of the astronomical measurements. Thus if epoch is defined as a certain number of completed revolutions of a solar body together with fraction of a revolution expressed in seconds, the precision is limited by the difficulty of determining the beginning and end of a revolution, and any small difference there may be between the fraction of a revolution as expressed in terms of the atomic or astronomical unit of time is quite negligible. Any changes in the phase of the atomically controlled quartz standard which may be necessary to synchronize atomic and astronomical time will be noted, so that a continuous record of the relationship between the two systems will be preserved, and any interval, however long, can be expressed in terms of the atomic unit. A time system of this kind, in which interval is based on the atomic unit but epoch on astronomical measurements, has been provided by the National Physical Laboratory for the past two years. It has caused no difficulties and has already been used for measuring the variations in the period of rotation of the Earth[12].

These problems have been discussed with my colleagues, Drs. H. Barrell and L. Hartshorn and Mr. J. V. L. Parry, and the form in which my views are presented owes much to these discussions. This communication is published by permission of the Director, National Physical Laboratory.

Delayed Signals in Ionospheric Forward-scatter Communication

IT has been reported[1] that long-delay multipath effects were observed when pulsed transmissions on 37 Mc./s. from Gibraltar were received in the United Kingdom during very high frequency forward-scatter propagation measurements. Delayed signals at multiples of approximately 20 msec. up to 80 msec. and traces of later components with about 130 msec. delay were detected. It was suggested that these were caused by a combination of reflexions at the $F2$ region and ground back-scatter behind the transmitting aerial, but the possibility of round-the-world propagation was discounted. The earlier delayed echoes were most probably due to the mechanism suggested, but observations at the Radio Research Station have shown that the signal with the longest delay was more likely to be due to round-the-world propagation.

Soon after the start of transmissions in March 1956, a weak pulse of intermittent nature was seen having a delay of about 140 msec. relative to the direct pulse received by E-region scattering. In the autumn, when $F2$ ionization was increasing, the pulse was again detected and was strong enough for its characteristics to be observed (see Fig. 1). Little distortion of the delayed pulse was apparent, showing that ground back-scatter was not involved. Directional measurements indicated that this pulse was arriving from the direction of Gibraltar and close to the great-circle path. The echo was most persistent during 0900–1030 hr. U.T., and at this time the complete great circle path was close to the twilight zone. Repeated echoes at 140 msec. intervals were occasionally seen similar to those observed at lower frequencies[2,3]. All these characteristics indicate that round-the-world propagation was occurring.

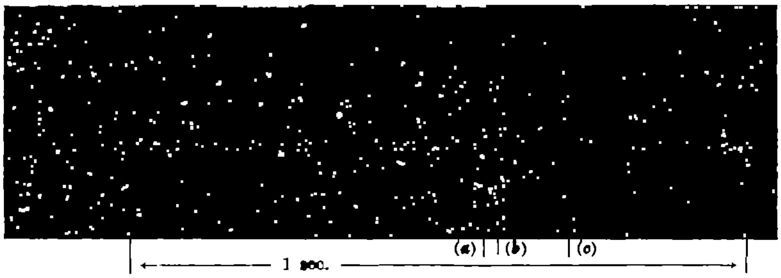

Fig. 1. High-speed record of pulses received at Slough. Time: 0916 U.T., October 18, 1956. (a) E-region forward scatter pulse; (b) $F2$-region and ground back-scatter pulse; (c) round-the-world echo.

Measurements of the time delay of the pulse were made and gave a value greater than that previously reported[3] for frequencies of 10–20 Mc./s.; this suggests that a longer effective transmission path is involved at 37 Mc./s. Possible mechanisms for this type of propagation and its effect on communication by E-region forward scatter are being studied and a full account of the work will be given later.

The work described was carried out as part of the programme of the Radio Research Board. This communication is published by permission of the Director of Radio Research of the Department of Scientific and Industrial Research.

Ionospheric Studies by the Lunar Radar Technique

INVESTIGATION of the ionosphere by the lunar echo technique is now being carried out at the Defence Research Telecommunications Establishment near Ottawa.

The transmitter consists of a klystron power-amplifier capable of delivering to the antenna better than 10 kW., in continuous operation. The exciter, which drives the power amplifier, operates at 488 Mc./s. derived by multiplication from a 1 Mc./s. crystal standard, stable to about 1 part in 10^8. The receiver is fed from a pre-amplifier which has a noise figure of 5 db. and a gain of 20 db. Local oscillator injection-frequencies are obtained from a crystal standard similar to that used at the transmitter. The receiver is a dual-conversion type with intermediate frequencies of 32 and 4 Mc./s. Synchronous detection is employed to give an audio output signal equal in frequency to the Doppler shift of the signal reflected from the Moon. An improved signal-to-noise ratio is obtained by following the Doppler shift with a narrow band-pass filter of variable centre frequency.

The transmitting antenna is a horn mounted at the focus of a 28-ft. paraboloid. The radio-frequency

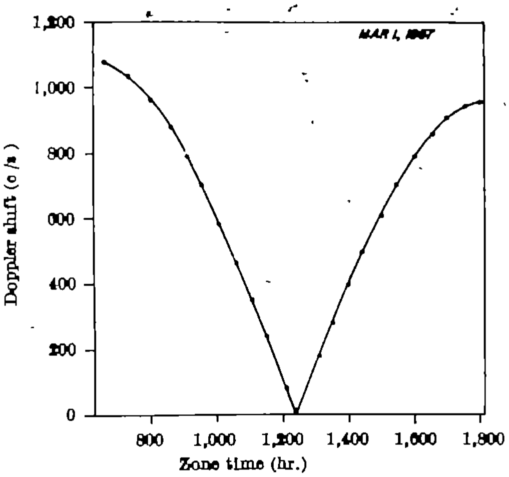

Fig. 1. Experimental measurement of the Doppler shift

feed is 3½ in. coaxial cable. The receiving antenna consists of orthogonal dipoles having 40 db. isolation and a reflector similar to that at the transmitter. The use of specially modified polar drive units permits continuous tracking of the Moon from moonrise to moonset.

At present, the transmitter is keyed 'on' for 2 sec. and 'off' for 4 sec., the receiver being gated 'off' while the transmitter is 'on'. On alternate 6-sec. periods the receiver is switched between the orthogonal dipoles. Lunar echoes are recorded simultaneously on magnetic tape and on a chart recorder.

Fig. 1 indicates the Doppler shift obtained experimentally for a complete lunar day on March 1, 1957. Fig. 2 shows typical lunar echoes recorded with a 40-msec. time constant. The lower trace covers a period of about two minutes, during which time the echoes were significantly different as received on the two orthogonal dipoles. The upper trace shows in more detail some of the fine structure of the echoes. The Doppler shifts are 430 and 900 c./s. for the upper and lower traces, respectively. The post-detection bandpass is approximately 4 per cent of the centre frequency.

Preliminary results indicate the presence of fading due to libration, as well as long-period Faraday rotation, both reported by other workers[1]. In addition, there appears to be a component of Faraday rotation which has a period of a minute or two. This is probably related to ionospheric irregularities. Also, there is a long-term fading not apparently accompanied by any rotation.

It is hoped to adapt the system for continuous-wave operation as well as for operation on a second frequency. Matched receivers will be used for continuous recording of the signals on both dipoles.

I acknowledge the invaluable assistance of Fred D. Green and Harold V. Serson in this project.

A Possible Auroral Enhancement of Infra-red Radiation emitted by Atmospheric Ozone

During the early part of this year, the nocturnal atmospheric emission in the near infra-red (to 15 microns) has been observed at College, Alaska, using a standard Perkin–Elmer single-pass monochromator with a rock-salt prism and thermocouple detector. The instrument was directed toward the southern sky, at about 20° above the horizon, giving an optical path of about four air masses.

The radiation received at 9·6 microns may be considered as due solely to ozone. Small fluctuations in the intensity of this emission are common, but on March 26, 1957, at about 11.55 p.m., an exceptionally large increase, amounting to about 18 per cent, was observed. This increase occurred immediately after the aurora had moved into the region of the sky covered by the instrument. Half an hour earlier, before the aurora had moved so far south, the ozone radiation was normal. This observation suggests that the 9·6 micron radiation may have been enhanced by the aurora, either by an increase in the amount of ozone, or in its temperature. Observations will be continued when the dark nights return. If this connexion between the aurora and radiation from the ozonosphere is confirmed, it will be additional evidence that the atmosphere is affected by the aurora at lower levels than was formerly thought likely.

It is not difficult to see how the effect could be produced. The spectrum of the aurora[1] may be assumed to extend farther into the ultra-violet than is observed from the ground, the short wave-length limit being set by ozone absorption. The Lyman series of hydrogen, for example, must be present, because the Balmer series is observed, and it is to be expected that radiation from oxygen and nitrogen of wave-length less than 3000 A. is also present. Absorption of this radiation by ozone already present could heat the ozonosphere; also some of the radiation might be effective in producing ozone. Van Allen and his collaborators have detected the presence of radiation believed to be X-rays (bremsstrahlung from auroral electrons[2]) near the auroral zone. This radiation was observed from 40 km. up, and its absorption must at least heat the atmosphere.

These relatively low-level auroral influences merit close study in view of their possible meteorological implications.

This work was partially supported by the Geophysics Research Directorate, of the Air Force Cambridge Research Center, Contract Number AF 19 (604) 1817.

Effect of Ionizing Radiation on Solid Catalysts

IT has been recognized for some time that the activity of solid catalysts might be affected by ionizing radiations, and a number of workers have studied the effect of X-rays on catalysts. Clark, McGrath and Johnson[1] observed a small increase in the activity of a platinum catalyst for the oxidation of sulphur dioxide in the presence of water vapour, and Harker[2] reported an increase in the uptake of hydrogen from the gas phase by copper and palladium during irradiation. However, Emmett and Jones[3] found that the speed of reaction of hydrogen and oxygen on a platinum/asbestos catalyst was not affected by irradiation, and Gotzky and Günther[4] obtained negative results for the reaction of hydrogen and chlorine on a variety of catalysts.

Taylor[5], using cobalt-60 γ-radiation, recently reported that the activity of γ-alumina for the hydrogen/deuterium exchange reaction at − 78° C. is markedly increased by quite small doses of radiation, and that the increased activity declined over two to four days at room temperature.

During the past two years, a study of the effect of cobalt-60 γ-radiation on solid catalysts has been in progress at the Fuel Research Station, and in view of Taylor's recent results, it may be of interest to record some of our results. The study has been directed toward finding effects which will persist under the conditions required for reactions of practical interest. It is common experience that the effects of radiation in solids rapidly disappear during quite short periods at room temperature or higher. However, an effect has been found which persists for at least 300 hr. at 280° C.

The main interest in the study has been in the catalytic synthesis of hydrocarbons from carbon monoxide and hydrogen (Fischer–Tropsch process). The synthesis reaction takes place in the presence of cobalt or iron catalysts. It was found that doses of radiation up to 2 × 10^7 r. effected no change in the activity of the catalyst or the composition of the products when using a reduced cobalt/thoria/magnesia/kieselguhr catalyst. Also it was found that irradiation of the reacting system during synthesis at a dose-rate of about 4 × 10^4 r./hr. had no effect on the rate of reaction in a static system. These results are not perhaps surprising in view of the fact that about 60 per cent of the cobalt is present as the metal.

However, a marked increase in activity has been observed when using unreduced iron catalysts. These catalysts are prepared by impregnating iron oxide (mill-scale) with potassium carbonate and calcining for 4 hr. at 1,000–1,300° C. Irradiations were carried out in nitrogen on samples which had been dried by evacuation at room temperature; as soon as the irradiation was completed, the samples were transferred to the catalyst testing units in an atmosphere of nitrogen or water gas, and the testing started. The doses used were in the range 1–5 × 10^7 r.

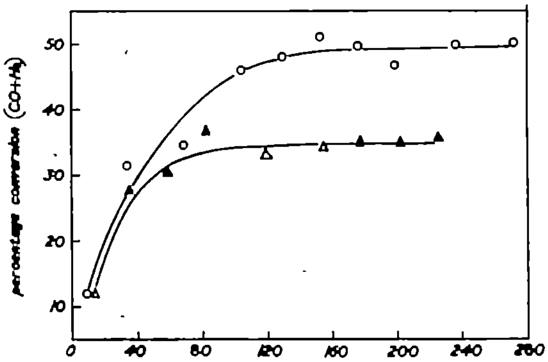

Fig. 1. Effect of irradiation on catalyst *A*. Tests carried out on 41 gm. of 72–170 mesh catalyst, in a fluidized bed system. Test conditions: temperature, 280° C.; pressure, 10 atm; space velocity, 986/hr., inlet gas, water-gas. ▲, Unirradiated; ○, dose 3·6 × 10^7 r.

When particles in the size-range 100–200μ were used for the synthesis in a fluidized system at 10 atm. and 280° C., increases of 10–40 per cent were observed in the rate of conversion of (CO + H_2) as a result of irradiation. This effect was observed with two different catalysts, prepared from different mill-scales and calcined at different temperatures, and in a total of seven experiments with irradiated catalysts, five comparison tests being carried out with unirradiated samples. The duration of the tests varied from 48 to 300 hr., and the high activity of the irradiated samples remained until the end of the tests in all cases. Fig. 1 shows activity plotted against time for a pair of experiments with one catalyst; similar graphs were obtained for the other catalyst tested.

Particles in the size range 0·2–5μ were tested in a system in which the catalyst was suspended in a high-boiling fraction of synthesis product through which synthesis gas was passed. In these experiments, it was possible to measure the yield of products as well as the gas conversions. The results of tests with one irradiated and two control samples are shown in Fig. 2. The increase in activity is larger than that observed using particles of 100–200μ of the same catalyst, being in the range 40–60 per cent.

No increase in activity was observed when catalyst particles in the size range 400–600μ were irradiated with a γ-dose of 4·8 × 10^7 r., or when large particles (1·2–2·4 mm.) were irradiated in the reactor BEPO (10^{18} n./cm.^{2} + associated γ-dose). The pile-irradiated catalyst had to be stored for some weeks at room temperature before testing so that the induced radioactivity could decay to a tolerable level, and thus this experiment is not strictly comparable with the others quoted.

The two main points of interest in these observations are the influence of particle-size and the persistence of the increased activity. Other work in these laboratories[6] on the effect of catalyst particle-size on the synthesis suggests that the active part of catalysts of this type is confined to a depth of 0·075–0·1 mm., that is, particles greater than 0·2 mm. have a region in the centre which is not available for the synthesis. It is interesting to note that the increase in activity

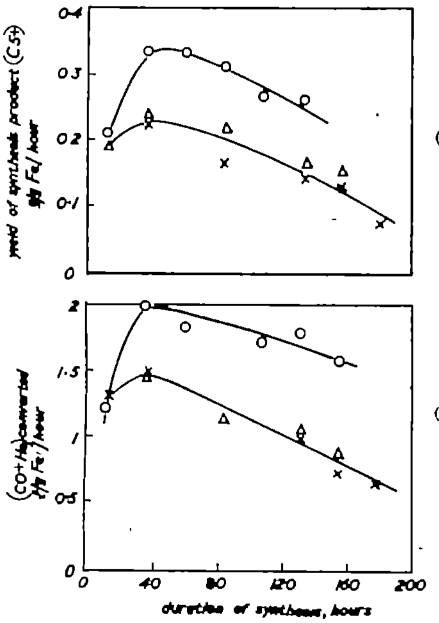

Fig. 2. Effect of irradiation on catalyst *B*. Tests carried out on 50 gm. of finely ground catalyst suspended in a paraffin wax medium. Test conditions: temperature, 285° C.; pressure, 20 atm.; space velocity, approx. 200/hr. based on slurry volume; inlet gas, water-gas. ×, △, Unirradiated; ○, dose 3·6 × 10^7 r.

induced by radiation only becomes apparent when the catalyst granules are less than this critical size.

From a study of the activity/time graphs, it is evident that the irradiated catalyst is not significantly more active than the untreated catalyst during the first few hours under synthesis conditions. It is thus unlikely that the primary changes produced by the radiation (electronic excitation, lattice imperfections) are directly responsible for the increased activity.

It appears rather that irradiation produces changes which facilitate and extend the 'conditioning' of the catalyst (partial reduction and the formation of iron carbides), which always takes place during the initial period of treatment under synthesis conditions, and which is accompanied by a marked rise in activity. This view is supported by the fact that irradiation does not increase the activity of these catalysts (100–200μ) for the decomposition of hexyl alcohol in an atmosphere of nitrogen.

Work is now in progress to examine further the nature of the changes produced and the reasons for the observed increase in the activity of these catalysts.

This work forms part of the programme of the Fuel Research Board of the Department of Scientific and Industrial Research, and this report is published by permission of the Acting Director of Fuel Research.

Molecular Weight Determination in Polyethylene Terephthalate

It has hitherto proved difficult to obtain molecular weight determinations on polyethylene terephthalate because normal values (approximately 20,000) fall in an experimentally difficult region. Recently, however, a method based on deuteration of the end groups has been developed for determining the number average molecular weight of this polymer.

Polyethylene terephthalate is a linear polyester in which the end-groups (shown by infra-red[1] and chemical analysis) are —OH and —COOH groups. Successive immersions of the polymer in fresh heavy water (D_2O) cause these groups to be replaced quantitatively by —OD and —COOD. If the dry polymer is then burnt, the water produced can be analysed for deuterium[2] and the total number of end-groups calculated. The total end-group content of a series of samples was found in this way and in each case the intensities of the —OH and —COOH infra-red absorptions at 3μ[1] measured. From these results a calibration method was devised for determining the total number of end-groups in any sample of polyethylene terephthalate directly from the intensities of the infra-red absorptions. Hence the number average molecular weight can be determined, no cyclic structures being present apart from very small amounts of a cyclic trimer[3].

Measurements have been made on a series of polyethylene terephthalate samples of different intrinsic viscosity. The intrinsic viscosities were measured with an Ostwald viscometer using a 1 per cent solution in *o*-chlorphenol. The results are shown in Fig. 1. It can be seen that there is a reasonably linear relationship between the intrinsic viscosity and the number average molecular weight $\overline{M}_n$. Assuming that $[\eta] = k\overline{M}_n^{\alpha}$, a regression analysis shows that $\alpha = 0{\cdot}77 \pm 0{\cdot}09$ and $k = (3{\cdot}0 \pm 1{\cdot}2) \times 10^{-4}$. Full details of this work are being published elsewhere.

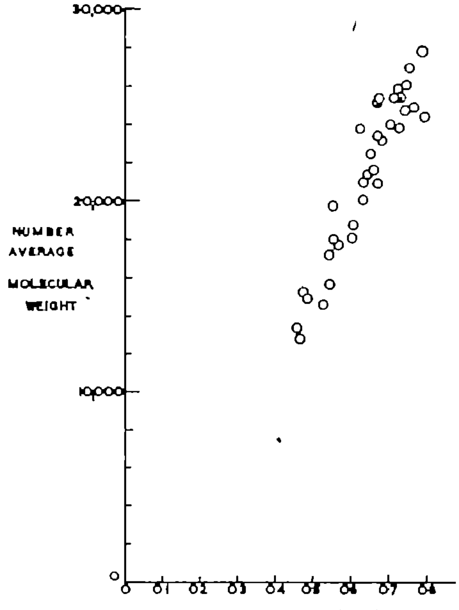

Fig. 1. Graph illustrating relationship between number average molecular weight and intrinsic viscosity for polyethylene terephthalate

Mechanism of Drying of Thick Porous Bodies during the Falling-Rate Period

Experiments carried out in this Department suggest that the mechanisms of drying in the constant and falling-rate periods are essentially the same except in one particular respect, namely, the value of the wet-bulb temperature of the air into which drying takes place.

Fig. 1 shows the usual constant and falling rates of drying obtained on a thick, porous bobbin of woven 'Terylene' with fairly large voids. Fig. 2 shows the temperature attained by four different layers within the bobbin at different times.

It will be seen that initially all layers approached the wet-bulb temperature of the air of 26° C. approximately. At point *A*, which coincided with the end of the constant-rate period, the temperature of the surface layer rose steeply to the dry-bulb temperature of the air. All other layers rose to another plateau of temperature, a 'pseudo wet-bulb temperature', *BCD*. The temperatures of layers of increasing depth within the bobbin left this plateau at different times, as shown at *B*, *C* and *D*. From the weight of the bobbin it appeared reasonable to conclude that the free surface of the water had just receded beyond the depth of the particular layer at the time at which the layer temperature left the plateau to rise towards the dry-bulb temperature of the air. Furthermore, the temperature distribution above each layer appeared to be in accord with this picture; that is, above this particular layer the bobbin was dry. There is a final kink at *E*, when the temperature of all layers rose more steeply than before towards the dry-bulb temperature of the air. This point coincided with the time when the bobbin was 'completely dry'.

The explanation appears to be as follows. A short time after the beginning and until *A*, water, with a surface temperature equal to the wet-bulb temperature of the air, is evaporating into the air stream. Between *A* and *B*, or thereabout, the first falling-rate period is a period of adjustment when the free surface of the water is receding into the interior of the bobbin while its temperature is rising to a new equilibrium temperature. The rate of drying should increase because of this rise in temperature; but, on the other hand, it decreases because the surface of the water is receding from contact with a moving air stream into contact with a stationary air pocket within the bobbin. The net result is a decrease. This period is short, and equilibrium is reached after point *B*. The surface of the water is now at the pseudo wet-bulb temperature. This temperature is the result of the equality of heat input due to the temperature gradient and heat output due to evaporation in precisely the same way that the ordinary wet-bulb temperature is attained in the presence of a moving air stream. It is in fact a wet-bulb temperature in stagnant air. As evaporation into stagnant air is less than that into moving air for the same surface temperature, both the heat input required by the surface and the drop from the dry-bulb temperature are smaller than before. Accordingly, the pseudo wet-bulb temperature is higher than the ordinary wet-bulb temperature.

As the free surface recedes beyond each layer, the temperature of the layer rises to a value intermediate between the dry-bulb temperature of the air and the pseudo wet-bulb temperature in accordance with the principles of heat conduction. The thermal con-

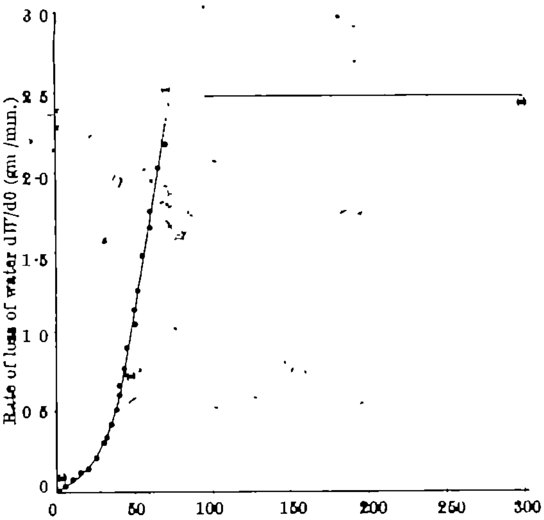

Fig. 1. Air speed, 435 cm./sec.; air temperature, 50·0° C

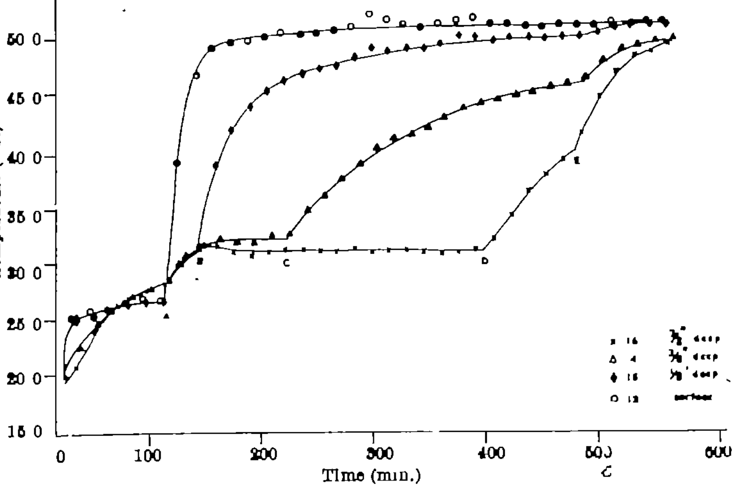

Fig. 2. Air speed, 435 cm./sec.; air temperature, 50 0° C.

ductivity of the wet portion is much higher than that of the dry material, so that all layers below the surface of the water are at practically the same temperature, both when the wet-bulb and when the pseudo wet-bulb temperatures are attained by the free surface. Finally, when the free surface of the liquid disappears, the stabilizing effect of evaporation disappears and the whole body behaves as a dry solid under a temperature gradient. This happens at *E*, when, it will be observed, there is a simultaneous kink in all temperature curves except that of the surface of the bobbin.

It is hoped to publish a more detailed account of this work elsewhere.

Para-Localization Energy (Free-Electron Molecular-Orbital) and Polarographic Half-Wave Potential of some Polynuclear Hydrocarbons

In a recent communication, Fernandez-Alonso and Domingo[1] have reported some numerical disagreements in their *para*-localization energy calculation with those of Basu[2]. In Fernandez-Alonso and Domingo's calculation the box dimension for ethylene was taken as equal to one bond-length (as well as half bond-length) more at each end. In Basu's calculation the box dimension was taken to be equal to the length of C—C double bond.

In the conventional free-electron approximation, the length of the box is extended half a bond-length at each end for aliphatic conjugated compounds in order to get agreement with their absorption spectra. This assumption, however, is not valid for ethylene, since this gives a resonance energy of benzene which is six times too high. This point has been discussed by Basu[3,4] in two subsequent papers. There is no physical reason for extending the box dimension more than half a bond-length in the case of ethylene alone. Because of this uncertainty the box dimension was not adjusted in Basu's calculation. The conclusion arrived at by Basu is necessarily limited by the basic assumptions made, and is not expected to be valid if the initial conditions are changed.

The *para*-localization energy of naphthalene recorded as 4·00 is due to a typographical error (the value refers to benzene)[5]. A fairly linear plot is obtained with *para*-localization energy values uncorrected for overlap. It is only an average linear plot that is expected in this type of calculation. In the calculation of *para*-localization energy with two electrons fixed on two carbon atoms, it is not known what changes are introduced in the bond-lengths of the rest of the molecule. So the introduction of overlap correction alone in this type of calculation is not very well justified. This is the reason why $E_{1/2}$ was not plotted against overlap corrected *para*-localization energy, although the values are given in the same table of Brown[4] from which Basu and Bhattacharya's data were collected, and although in the first free-electron calculation Basu[2] compared his values with the overlap corrected values of Brown.

Inactivation of Antihæmophilic Globulin by Thrombin

Normal plasma defibrinated by addition of 'Thrombin Topical' (Parke Davis), 5 units per ml., loses its antihæmophilic activity[1]. In the experiments described here, each of the reagents in the thromboplastin generation test[2] (platelets, serum, plasma adsorbed with barium sulphate and *M*/40 calcium chloride) in turn was incubated at 37° C., for periods of three minutes and longer, in the presence of thrombin, and then used in the thromboplastin-generating mixture. Initially 'Thrombin Topical' was used, generally in concentrations of the order of 0·15 unit per ml. In every case, the expected acceleration of thromboplastin generation was observed[3]. However, while this treatment of the platelets, serum and calcium had no effect on the potency of the thromboplastin eventually generated, the 'thrombinized' and pre-incubated adsorbed plasma consistently yielded a much weaker thromboplastin than the control. Thus, pretreatment of the adsorbed plasma with 'Thrombin Topical' converted a normal thromboplastin generation curve into one resembling that found in hæmophilia. This effect was found to be irreversible and unaffected by dilution.

Since adsorbed plasma contributes two essential constituents of blood thromboplastin, factor V (Ac-globulin, pro-accelerin) and antihæmophilic globulin, further experiments were carried out using mixtures of normal, hæmophilic and factor V-deficient adsorbed plasma, untreated or pretreated with thrombin, in various combinations. The results showed clearly that the factor inactivated was antihæmophilic globulin and not factor V.

The experiment was repeated using very fresh serum (at most five minutes old) as the source both of thrombin and of the serum thromboplastin constituents; that is, the fresh serum was diluted and incubated with normal adsorbed plasma for three minutes before platelets and calcium were added. The resulting thromboplastin generation was greatly impaired (Fig. 1). As the thrombin activity of the serum declined, so did its ability to inactivate the adsorbed plasma.

When heparin in a concentration of 0·075 unit per ml. was included in the incubated mixture of adsorbed plasma and thrombin (or very fresh serum), the inactivation of antihæmophilic globulin was prevented. In this case, evidently, heparin was acting as a true antithrombic agent in a concentration too low to prevent thromboplastin formation (0·025 unit per ml. in the final mixture).

These findings support Alexander's suggestion that the disappearance of antihæmophilic globulin during

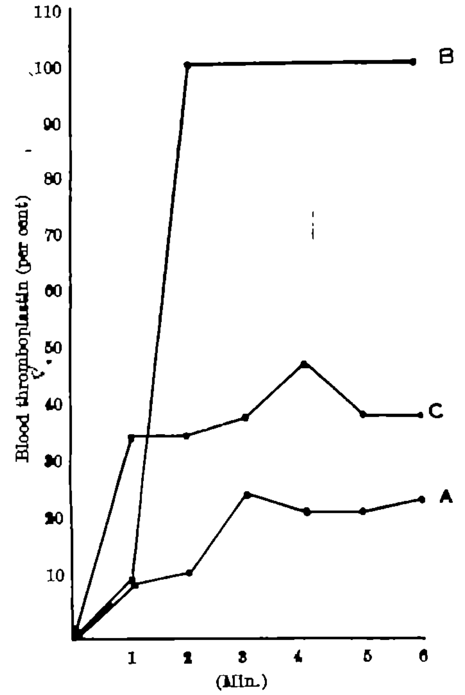

Fig. 1. Thromboplastin generated from normal platelets mixed with *A*, normal adsorbed plasma pre-incubated for 3 min. with normal, very fresh serum; *B*, same as *A*, but mixture recalcified without pre-incubation, *C*, same as *A*, serum having stood 20 min.

clotting is caused by thrombin. Indeed, the concentration of thrombin was too low, in all the above experiments, to affect any other clotting factor, including fibrinogen. This action of thrombin may have a physiological significance meriting further investigation.

Insensitivity of Chicken Cholinesterase to Specific Inhibitors of True- and Pseudo-Enzyme

The classification of cholinesterase as pseudo- or true-enzyme does not necessarily imply that the components of each group have identical properties. Experimental evidence has been given suggesting the different sensitivity to inhibitors of the enzymes belonging to the same group[1,2].

While we were looking for further experimental support for this evidence, we studied the sensitivity of the most commonly employed enzymatic preparations to three characteristic inhibitors of cholinesterase: eucupine (*iso*amylhydrocupreine hydrochloride), physostigmine (salicylate) and *C.T.*3318 (*bis*(piperidinomethyl coumaranyl-5)ketone diiodomethylate). It has been demonstrated that eucupine is a preferential inhibitor of pseudo-cholinesterase[3], whereas *C.T.*3318 is a selective inhibitor of true-cholinesterase[3,4]. Cholinesterase activity was evaluated titrimetrically[5]. Sera were diluted with saline until they were able to destroy approximately one-third of substrate in 3 hr. at 37° C. Brain preparations were obtained from the whole brain of small animals or from basal nuclei of big animals, grinding the tissues with saline. The emulsions so obtained were diluted until destruction of one-half of the substrate occurred in 3 hr. at 37° C.

Rat	$>1·3 \times 10^{-6}$	$>0·7 \times 10^{-4}$	$0·24 \times 10^{-5}$
Dog	$0·34 \times 10^{-6}$	$>0·7 \times 10^{-4}$	$0·38 \times 10^{-6}$
Brains:			
Horse	$0·27 \times 10^{-7}$	$>0·7 \times 10^{-4}$	$0·43 \times 10^{-5}$
Hog	$0·3 \times 10^{-7}$	$0·32 \times 10^{-4}$	$0·24 \times 10^{-6}$
Rabbit	$0·65 \times 10^{-7}$	$0·52 \times 10^{-4}$	$0·24 \times 10^{-5}$
Chicken	$>1·3 \times 10^{-5}$	$>0·7 \times 10^{-4}$	$0·13 \times 10^{-6}$
Duck	$>1·3 \times 10^{-6}$	$>0·7 \times 10^{-4}$	$0·48 \times 10^{-6}$
Pigeon	$>1·3 \times 10^{-5}$	$>0·7 \times 10^{-4}$	$0·15 \times 10^{-5}$
Guinea pig	$0·65 \times 10^{-7}$	$>0·7 \times 10^{-4}$	$0·53 \times 10^{-6}$
Rat	$1·3 \times 10^{-6}$	$0·23 \times 10^{-4}$	$0·6 \times 10^{-6}$
Dog	$0·17 \times 10^{-7}$	$>0·7 \times 10^{-4}$	$0·24 \times 10^{-6}$

The results given in Table 1 show the 50 per cent inhibiting concentrations of the drugs. These indicate that the cholinesterase activity of chicken's, duck's and pigeon's blood serum and brain and that of rat's blood serum is scarcely affected by either eucupine or *C.T.*3318. This is not a result of general insensitivity of chicken enzyme to all inhibitors; for the enzyme is inhibited by physostigmine. Moreover, sensitivity to inhibitors is not conditioned by a particular substrate; all the above-mentioned peculiarities persist when acetylcholine is substituted for acetyl-β-methylcholine as substrate.

Because it was possible that the presence of an antagonist could be responsible for the insensitivity of chicken cholinesterase to *C.T.*3318, in Table 2 are given the results of an experiment in which I used mixed rabbit's and chicken's blood sera; it is apparent that only the rabbit's enzyme has been antagonized. Therefore we can assume that the enzyme(s) found in the avian tissues used, like those of rat's tissues, differs as regards sensitivity to eucupine and *C.T.*3318 from classical pseudo- and true-cholinesterase. It is clear from these results that crude preparations of

Table 2. Sensitivity of Rabbit's Blood Serum Cholinesterase to *C.T.*3318 in Presence of Chicken Blood Serum

Phoenix Heat Resisting glass tubing "does the job" better. Electrically melted, its pliability is unrivalled. It can be shaped —safely—with no fear of fleddage or distortion. The low coefficient of expansion of Phoenix prevents thermal shock and overcomes the vulnerability of this medium in working.

The mechanical and thermal strength of Phoenix workable glass tubing possesses immutable advantages which meet the widest possible range of industrial conditions. Phoenix, produced by the latest machine methods, ensures true diameter, true bore and roundness. The clarity of this heat resisting glass provides an easy check on flow and density. The technician *knows* the advantage of Phoenix.

AVAILABLE IN 14 lb. STANDARD BUNDLES

Phoenix Heat Resisting glass tubing is packed in 14-lb. standard bundles—useful for the small and large user. While standard sizes are available ex stock, special requirements can be dealt with promptly. May we send you our catalogue ?

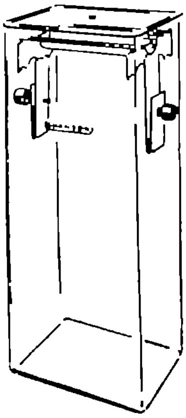
SHANDON

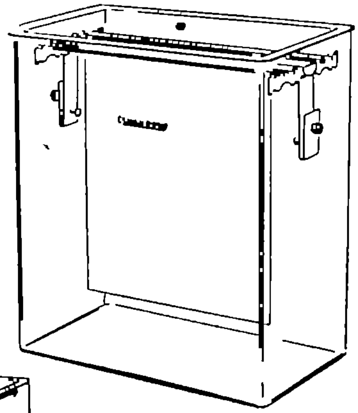
A COMPLETE RANGE OF ALL-GLASS TANKS FOR PAPER CHROMATOGRAPHY



The finest range of tanks available for this specialised analytical technique. All models have precision ground edges and plate glass lids with frosted borders. Internal fittings are instantly removable and fully interchangeable.

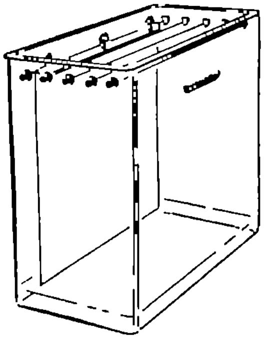
9″ and 12″ Universal Strip Chromatanks

2110 and 2120. 9″ and 12″ long × 7″ wide × 22½″ high for both ascending and descending chromatography.



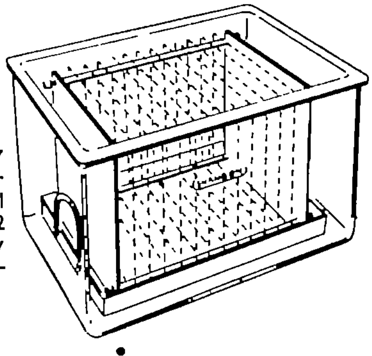
20″ "Two-Way" Chromatank

2130S. The largest one-piece glass tank available for one- and two-dimensional chromatography. 20″ long × 8″ wide × 20″ high. Takes filter paper sheets up to 18¼″ × 22½″.



13″ Universal Sheet Chromatank

2160S. 13½″ long × 7″ wide × 14½″ high, takes paper 31·5 × 33·5 cm. (about 12½″ × 13″). Easily adaptable for either ascending or descending techniques.



Multi-Sheet Frame Chromatank

2150. 15″ long × 11″ wide × 10″ high. For ascending 2-dimensional chromatograms of 2 sheets simultaneously and under identical conditions.

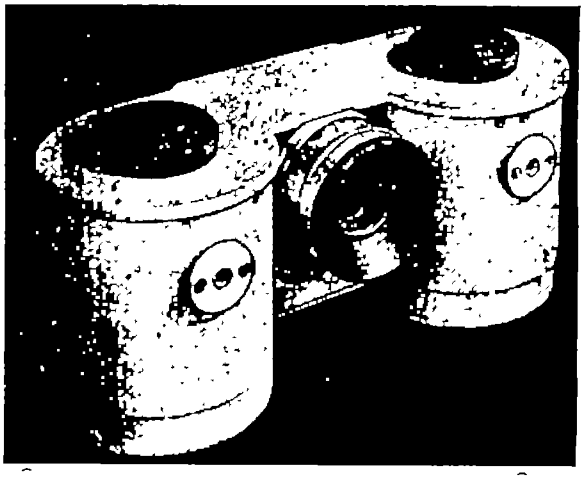
automation in photographic recording



The Shackman Autocamera is a recording instrument designed to cover a wide field in industrial and scientific work where the automatic production of micro-films is required. It is a precision instrument suitable for all purposes where long periods of visual observation and manual recording are impracticable, such as Oscilloscope Recording, Process Timing, Photomicrography and Instrument Recording. It can be fully automatic in its operation, requiring only a short single electrical impulse to operate the shutter and transport the film. A full range of accessories is available including control units and intervalometers. The Autocamera is adaptable also for industrial photography, stereoscopy, document copying and many other special applications.

Effect of Contrasted Planes of Nutrition on the Carcass Composition of the East African Dwarf Goat

The classic studies of Hammond[1] on the mutton qualities of sheep initiated a great volume of work on the problems associated with the production of high-quality meat. The chief technique used in this field has been that of 'quantitative growth analysis'. By this means, changes due to different genetic factors between breeds within a species[1,2] and changes due to different patterns of growth have been studied, and the results interpreted in terms of the theories of allometric and heterogenic growth and centripetal development first postulated by Brody[4] and Huxley[5].

The majority of past experiments has been conducted on a basis of quantitative analysis of carcass composition of animals from different treatments slaughtered at equal live-weights. Large and statistically significant differences between the composition of high- and low-plane nutrition wet carcasses have been found.

A series of replicated experiments has recently been carried out at the Serere Experiment Station, Uganda, on the effect of plane of nutrition on the goat, and the material has been examined on a basis of slaughtering in a manner such that the mean dead-weights were equal after all dissectable fat had been removed. Two dissection stages were employed, the first at 16-lb. dissectable fatless dead-weight (point of inflexion of the exponential growth curve) and the second at 30-lb. dissectable fatless dead-weight (mean weight at sexual maturity). Three goats selected at random from each treatment and each sex were dissected at each stage.

The overall picture was one of marked similarity in carcass composition between the four treatments employed, high–high, low–low, high–low, and low–high planes of nutrition. The difference in the weight of muscle, and the small differences demonstrated in the weights of the rumen, reticulum, omasum, abomasum, heart, pancreas, kidney, spleen and thymus were only statistically significant at the 16-lb. stage when the heterogenic changes in these organs were most pronounced. The only organs to demonstrate statistical differences between treatments at the 30-lb. stage were the liver and the male gonads. Differences were also found in certain bone measurements but not in bone-weights. The extent of the large treatment differences on the growth-rates of the experimental kids can be seen in Fig. 1.

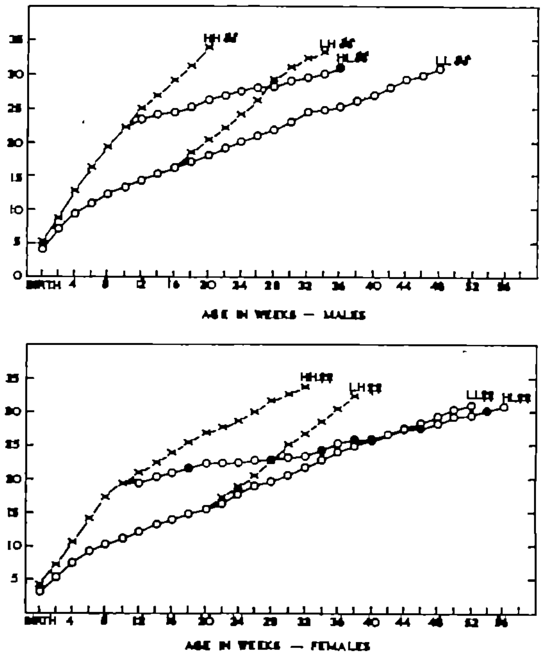

Fig. 1. Effect of plane of nutrition on growth curves of kids

Table 1. Percentage Composition of the Goat Carcass Minus Dissectable Fat on a Wet-Weight Basis at the 16-lb. Stage

The division of the carcass into its saleable and non-saleable portions showed that there were no statistically significant differences of agro-economic importance at the mature dissection stage of 30 lb., although such differences were apparent at the immature stage of growth. The effect of sex and treatment on the major tissues is summarized in Tables 1 and 2. These results show that the large differences found by other workers in the carcass proportions of mature animals reared on different planes of nutrition must be largely ascribed to the differences which such treatments exert on the percentage of fat in the body. In addition, within any given treatment and for any given sex, the amount of fat in the carcass has a higher standard error than any other organ or tissue, and hence the statistical precision can be greatly increased by working with the vital organs and tissues only, on the basis of bodies of equal weight after all dissectable fat had been removed. It is the effect of treatment on the vital organs of the body which is of the greatest biological significance, and the present work shows that this effect is much less in the mature animal than past work has indicated.

Detailed results of the experiments are being reported elsewhere.

I thank Dr. John Hammond and Dr. E. G Holmes for their interest and advice throughout the course of this work, and the Makerere College Research Grants Committee for financing the project.

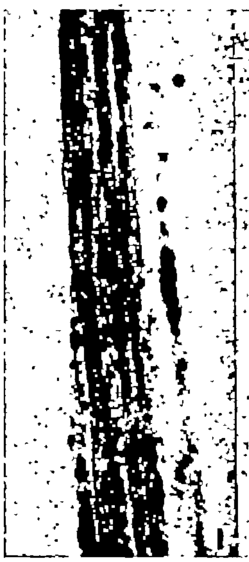
Temperature Effects in Mammalian Nerve Regeneration

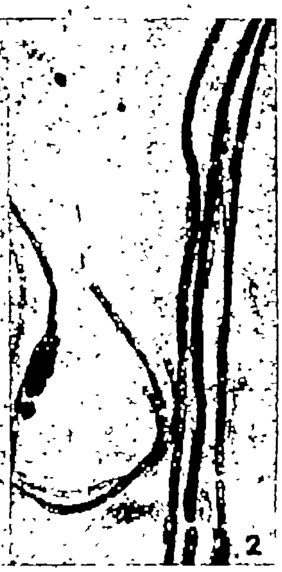
Many attempts have been made by the use of various drugs and hormones and by electrical stimulations to influence the rate at which mammalian nerve fibres regenerate after injury. None of these has been successful. It has, however, recently been shown that in poikilothermic animals such as the frog[1] and the lizard[2], nerve regeneration following upon injury is greatly affected by the temperature of the environment in which the animals are kept.

In 1908 Dieneka[3] investigated the effect of temperature upon the early stages of axonal regeneration in a mammal; he concluded that regeneration in animals kept at 30° C. had progressed in three days to a stage reached only after seven to eight days in others kept at 12–14° C. His animals (rabbits) were kept no longer than twelve days following operation, and he was unable to state, therefore, whether the effect of temperature extended beyond the preliminary stages of axonal outgrowth.

Experiments have been carried out on the ventral nerve in the tail of the rat which supplies both the skin and the short intervertebral muscles. It is obvious to the touch that the rat's scaly and almost hairless tail is considerably affected by the temperature of its surroundings, and it has been shown by Huggins, Blocksom and Norman[4] that temperatures here, even within the vertebral bodies, may be considerably below that of the peritoneal cavity. The nerve was crushed aseptically under ether anæsthesia and the animals kept afterwards for various periods in either a cold room at 2–2·5° C. or in a normally warmed room at 18–21° C.



1



2

In animals kept at 2–2·5° C., no normal axons could be seen after ten days, and although a few myelin sheaths appeared normal over full internodal lengths, most were represented by strings of vacuoles or 'digestion chambers'. After twenty-two days, all myelin sheaths as well as axons had degenerated, and up to thirty-five days (Fig. 1) no evidence of the presence of regenerating fibres could be found.

In animals kept for ten days at 18–21° C. myelin sheath degeneration was complete, as was axonal degeneration in the more distal part of the stump. But a large number of fine fibres, presumably regenerating axons, were present immediately distal to the crush, lying in the Schwann tubes together with Schwann cells and the debris from the original axons. In animals kept for twenty-one days at the same temperature, only scattered droplets of degenerated myelin were found, and in the first and second centimetres below the level of the crush, fine lightly myelinated fibres were present; fine axons (unmyelinated) extended at least 7 cm. below the crush. In Fig. 2 similar lightly myelinated fibres from an animal in which the nerve had been crushed thirty-five days before death are shown. The condition of the nerve contrasts strongly with that from an animal kept for the same period at 2–2·5° C. (Fig. 1). After forty-eight days, myelination was found as far as 6 cm. below the crush level.

There seemed to be no doubt that the fibres which were found subsequent to crushing in animals kept at 18–21° C. were regenerating axons, in many of which remyelination was fairly advanced. This was confirmed by measurements of internodal lengths. All internodal lengths were short and relatively uniform as compared with those of fibres from the normal nerve. Vizoso and Young[5] have shown that short and uniform internodal lengths are characteristic of regenerating fibres, and fibres showing nodes of any kind were absent in animals kept in an environmental temperature of about 2° C.

These experiments show that regeneration in a mammalian nerve can be completely inhibited by an environmental temperature near freezing point for at least thirty-five days, although by that time all fibres show advanced degenerative changes: at environmental temperatures near 20° C., regeneration proceeds rapidly. It is not yet known what temperature may be optimal for this process.

It is perhaps relevant that Barcroft and Edholm[6] have recorded temperatures in the deep muscles of the limbs of man and have shown that these may be as much as 6° C. below rectal temperature after exposure to cool air, and as much as 17–18° C. below rectal temperature after exposure to cold water. Taken in conjunction with the present findings, this suggests that environmental temperatures may be of considerable general significance in affecting the rate of recovery after nerve injury.

Lampbrush Chromosomes in Insects

The lampbrush chromosomes have been described in the male germ-cells of Orthoptera[1] and more widely in vertebrate eggs. Recently, in this laboratory also, these have been observed in the male germ-cells of not only the short-horned grasshoppers but also the gryllids. Our preparations were made after excellent fixation in Sanfelice and Bouin–Allen fluids, and these were stained with 0·5 per cent iron hæmatoxylin.

Apart from their morphology, the appearance of lampbrush chromosomes, in these insects, is correlated with the growth of the auxocyte. The premeiotic resting cell enters the leptotene stage directly without any significant growth in size. During pachytene, the cell enters the growth period and simultaneously the autosomal bivalents assume the lampbrush form, which persists until late diakinesis, when the cell has grown to its full size. In the normal mitotic cycle, the growth of the cell, which usually takes place in the resting period, is accompanied by practically the complete depolymerization of the nucleic acids, with the despiralization of the chromonemata. The lampbrush appearance of the chromosomes in the germ-cells of these insects may be physiologically correlated with the cellular growth and depolymerization, unaccompanied, however, by the complete suppression of the progressive meiotic changes in the chromosomes. The same is, perhaps, true of the oocytes.

The diffused or confused stage of Heteroptera, which usually interrupts the diplotene stage at its very beginning, may be regarded as representing a still further step. Similarly, the complete 'resting' condition of the diffused nucleus in most heteropterans represents the growth of the cell with complete depolymerization of the nucleic acids, unaccompanied by the complete suppression of the progressive meiotic changes in the autosomes. Consequently, as they reappear out of the confused stage, they have already undergone a good deal of contraction, with the terminalization of most of their chiasmata. The representation of the diffused lampbrush elements in some pyrrhocorid bugs studied by us points to the common nature of growth both in Heteroptera and Orthoptera, which, in the former, is accompanied by the more or less complete depolymerization of the nucleic acids and, in the latter, by its incomplete depolymerization and consequently the lampbrush appearance of the chromosomes. The approach to a state of complete depolymerization of the nucleic acids and very slight growth of the auxocyte at the early diplotene in the grasshopper, *Poecilocerus pictus*, result in a comparatively rare occurrence of the lampbrush fibres in that species.

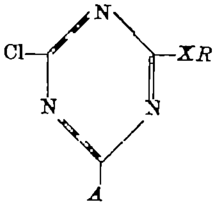
New *s*-Triazine Herbicides

In the course of investigations on *s*-triazines, we have discovered a new synthesis of 2-alkoxy- and 2-alkylthio-4,6-dichloro-*s*-triazines. These substances can be obtained by the reaction of an alcohol or a thiol with cyanuric chloride and 2,6 *α* collidine as the acid acceptor. The yield was approximately 80–90 per cent. In a further systematic investigation, we found that in these compounds the chlorine atom can be specifically substituted in good yield by an alkylamino, alkyloxy or alkylthio group.

Compounds with the structure:



in which X is —NH—, —O— or —S—, R is an alkyl group and A is chlorine or YR(Y may be only —O— or —S—), exhibited strong phytotoxic activity on many plant species (patents applied for)

Illustrative for this action is Fig. 1, which shows the results of spraying chickweed, beet, tomato, oats and beans (from left to right) with 1 per cent solution of 2-pentoxy-4,6-dichloro-*s*-triazine (*TR* 110) in a quantity corresponding to 10 kgm. per hectare. 2-*n*-Butoxy-4,6-dichloro-s-triazine (*TR* 14) and 2-*n*-butylthio-4,6-dichloro-s-triazine (*TR* 35) gave similar results. Fig. 2 shows a control series of pots.

By varying the alkyl group R, we found that the triazines with a side-chain of three to six carbon

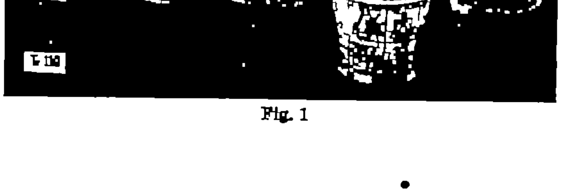


Fig. 1

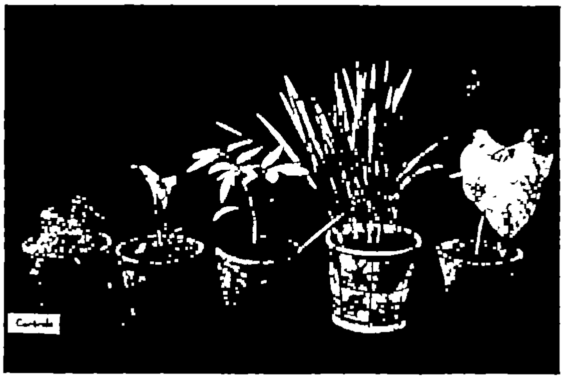

Fig. 2

atoms had the highest activity. The herbicidal activity was determined in small field-trials of 1 m.[2]. In this field there were growing lambs' quarters (*Chenopodium album*), chickweed (*Stellaria media*), small nettle (*Urtica urens*) and blue grass (*Poa annua*). The weeds were sprayed with 1 per cent solutions of *TR* 14, *TR* 35, 2-*iso*propylamino-4,6-dichloro-*s*-triazine (*TR* 31) and 2,4-*bis*(diethylamino)-6-chloro-*s*-triazine (Geigy 444 [1-3]), in a quantity corresponding with 10 kgm. per hectare. With this concentration Geigy 444 caused only slight damage to the plant growth. With the other s-triazines mentioned, all the weeds were killed with the exception of blue grass, which recovered after a time.

The new triazines are promising as pre-emergence herbicides. Further extensive field-trials will be attempted. A more detailed account of this work will be published elsewhere.

A New Thiol in Legumes

A NEW thiol has been found in the red kidney bean, *Phaseolus vulgaris*, and in certain other legumes. The thiol is the principal non-protein thiol of these plants. Glutathione, when present, occurs at much lower concentrations. A provisional name, 'phaseothione', has been assigned to this compound, pending the determination of its chemical structure.

In a survey (unpublished work) of the non-protein thiols in plants, conducted by means of a very sensitive paper chromatographic procedure[1], a major unknown thiol component, 'phaseothione', was detected in extracts of *Ph. vulgaris* leaves. About 1 μmole of phaseothione was present per gram of leaf; lower concentrations were detected in the roots, stems and pods. A trace of glutathione was sometimes identified by precipitation with mercuric nitrate and subsequent chromatography, but the concentration was less than 5 per cent that of phaseothione. The new thiol was also found in the leaves of the lima bean (*Ph. limensis*), the soy bean (*Glycine max*), and white clover (*Trifolium repens*). In the leaves of other legumes, however (*Albizzia julibrissia*, *Arachis hypogea* and *Pisum sativum*), glutathione was found at concentrations typical of leaves generally. No phaseothione was found in these legumes or in twenty-one other species and genera. The results of analyses on several legumes are shown in Table 1.

Table 1. MAJOR NON-PROTEIN THIOL COMPONENTS OF SEVERAL LEGUMES

Presence or absence of glutathione was determined by co-chromatography (cf. Fig. 1). Quantities estimated by visual comparison with known amounts of glutathione; quantity of phaseothione estimated by assuming the specific intensity of colour development was identical with that of glutathione. Limit of detection: 0·05 μmole per gm wet weight

Plant	Estimated quantity of thiol component in μmole/gm. wet weight	
	Glutathione	Phaseothione
Albizzia julibrissia Durazzini (mimosa tree)	0 5	0
Arachis hypogea L (peanut)	0 5	0
Glycine max (L.) Merr (soy bean)	0	0 5*
Phaseolus limensis Macfad. (lima bean)	0	0·2
Phaseolus vulgaris L. (red kidney bean)	0	1
Pisum sativum L (pea)	0 4	0
Trifolium repens L. (white clover)	0	0 5

* Glutathione not detected; interfering substances hindered colour development in region of phaseothione

Analysis of phaseothione indicated that it contained an amino-acid group, and, as shown in Fig. 1, often

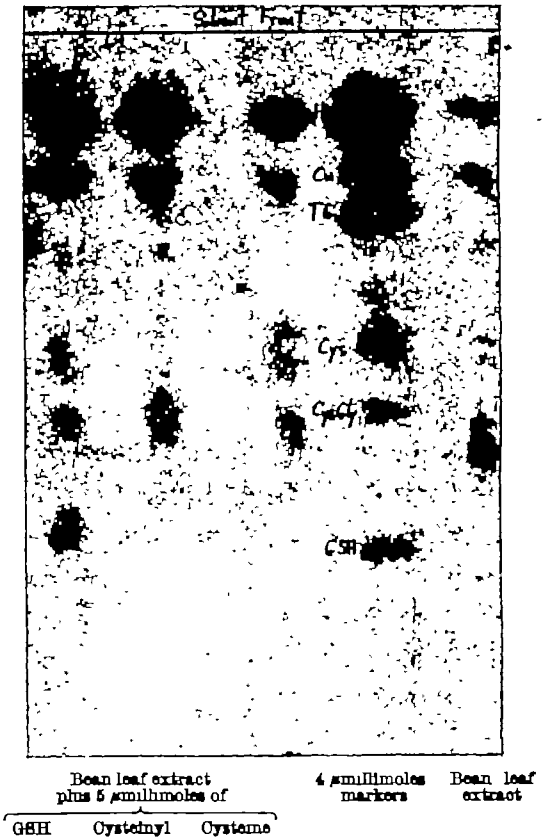

Fig. 1. Co-chromatography of bean leaf thiol. Authentic thiols and leaf extract of *Ph. vulgaris* were treated with N-(4-hydroxy-1-naphthyl)-*iso*maleimide, chromatographed in *iso*-propanol/*n*-butanol/*N*-acetic acid (75 : 10 : 15), and the thiol components detected with a diazo reagent (ref. 1). HNI, the *iso*maleimide reagent; Cn, an unidentified contaminant (ref. 1) in the reagent; TG, thioglycollate; Cys, cysteine; CysGly, cysteinyl glycine; and GSH, glutathione. The amount of the leaf extract applied to the paper corresponded to 2 mgm. wet weight of tissue

ran with an R_F nearly equal to that of cysteinyl glycine. In *iso*-propanol/*n*-butanol/*N*-acetic acid (45 : 40 : 15 v/v), however, the R_F of phaseothione was 0·66 and that of co-chromatographed cysteinyl-glycine, 0·70. In water-saturated butanol, the R_F values were 0·15 and 0·19, respectively. Phaseothione is apparently not identical with, but may be similar to, cysteinyl glycine. Glutathione, added to bean leaves and extracted, yielded glutathione unchanged on the chromatogram.

Glutathione, determined by the glyoxalase assay, was previously reported[2] in *Ph. vulgaris* hypocotyls at a concentration of 0·4 µmole per gram. Chromatographic analysis of hypocotyl tissue in our hands showed phaseothione at approximately this concentration. Phaseothione, therefore, may be in that class of cysteine-containing thiols with appreciable glyoxalase coenzyme activity[3].

It had been generally assumed that glutathione is ubiquitous in living tissues[4]. Apple fruit constituted the single exception[5]. Since phaseothione may occur in several legumes in place of glutathione, information on the enzymatic functions of the substance, possibly analogous to those of glutathione[6], will be of special interest.

Part of this study was conducted in the laboratory of Prof. A. C. Leopold, Horticulture Department, Purdue University, to whom I am most grateful. Support was provided by a research grant, *C*-2204, from the National Institutes of Health, U.S. Public Health Service, to Prof. Leopold, and by the Milton Fund of Harvard University.

Phosphorylase Inhibitor in Potato : Separation from Activator and Possible Relation to Chlorogenic Acid

In a previous study of the factors in ethanolic extracts of potato which influence the activity of potato phosphorylase, it was found that although the observed shortening of the amylose chains synthesized by this enzyme could, in part, be attributed to the presence of inorganic orthophosphate in the extracts, the latter did not cause an inhibition of phosphorylase as measured by the rate of liberation of phosphate from glucose-1-phosphate in the presence of starch primer[1]. However, demonstration of primer (activator) activity of such extracts after de-ionization with ion-exchange resin implied the presence of true inhibitory activity in the extracts. Presumably this inhibitory action is obscured by the presence of activator (primer). Since no inhibitory activity could be demonstrated in the acid or alkaline eluates from cation-exchange columns after chromatography of the potato extracts, it would appear that the inhibitor is acidic. However, attempts to recover inhibitory activity in acid eluates from anion-exchange chromatography of the extracts was complicated by the appearance in these eluates of trace amounts of material, derived from the columns, which in themselves possessed considerable inhibitory activity. In the case of weak phenolformaldehyde resins, the inhibition was traced to the inactivating effect of formaldehyde, whereas polystyrene-quaternary amine resins yielded a green non-fluorescent material devoid of nitrogen which also exhibited inhibitory activity. Pretreatment of the resins under a variety of conditions did not eliminate subsequent elution of inhibitory material.

An alternative route to the separation of activator from inhibitor was afforded by the finding that addition of ethanol to 90 per cent (v/v) at 4° C. to concentrated extracts precipitates most of the activator but not the inhibitor activity. (Further activator activity can be precipitated from aqueous solutions of the inhibitor with ammonium sulphate.) After the removal of the ethanol and tyrosine, which remains undissolved when the supernate from such treatment is dried and taken up in water, further purification of the inhibitor could be achieved by a brief treatment with activated charcoal, followed (after appropriate dilution) by ion-exchange chromatography on 'Dowex-1-acetate' columns by a procedure similar to that developed by Palmer[2]. Upon elution with increasing concentrations of acetic acid, most of the inhibitory activity (determined after vacuum distillation of the acetic acid and neutralization to *p*H 6·0) was found to come through with the eluate fractions between 0·33 *M* and 1 *M* acetic acid.

The inhibitory activity derived from the resin already mentioned could be separated from that derived from the potato extract by taking advantage of the observation that 'true' but not the artefact inhibitory activity is insoluble in absolute ethyl alcohol. Between 25 and 85 mgm. of this final fraction was obtained from 1 kgm. of peeled potatoes, corresponding to 22 gm. of solids in the original crude ethanolic extract. 2 mgm. of this fraction per ml. of enzyme standard incubation mixture[1] inhibited 5 units of phosphorylase to the extent of 66 per cent. (One unit of enzyme will release 1 µequiv. of inorganic phosphate in 30 minutes in 1 ml. of digest containing 11 µequiv. glucose-1-phosphate and 100 µgm. of soluble starch in 0·2 *M* acetate buffer, *p*H 6·0, 37° C.) This purified inhibitor preparation, when neutralized and dried, lost activity and turned brown when stored at room temperature. It contains very little organic phosphorus and nitrogen and is not soluble in acidulated ether and most other organic solvents.

Although the chemical nature of the inhibitor has not been elucidated, the observations described above and the following properties indicate that we may be dealing with a compound or compounds related to chlorogenic acid. Thus the inhibitory activity of preparations obtained from peelings of potatoes is several times that obtained from extracts of peeled potatoes. According to Johnson and Schaal[3], chlorogenic acid is concentrated in the periderm layer of the potato tuber. Preparations derived from peel turn deep orange when treated with acid molybdate; this reaction has been found to be characteristic for *o*-diphenols but not for monophenols. This was true to a lesser extent of preparations from peeled tubers.

Finally, it has been demonstrated that chlorogenic acid itself is a fairly potent inhibitor of potato phosphorylase. Thus 10^{-3} *M* chlorogenic acid caused 50 per cent inhibition of enzyme activity in a standard assay system containing 2·4 units of phosphorylase[1]. Apparently most of the inhibition is related to the caffeic acid moiety of chlorogenic acid, inasmuch as the degrees of inhibition obtained under the same conditions in the presence of 0·05 *M.* concentrations of acids were as follows: chlorogenic, 93 per cent; caffeic, 85 per cent; quinic, 12 per cent. The mechanism and possible metabolic importance of this inhibition await further investigation.

Germination of Oospores of *Phytophthora erythroseptica*

GERMINATION of comparatively young oospores of *Phytophthora erythroseptica* has been obtained following passage through the digestive tract of the garden snail, *Helix aspersa*. These oospores were produced in oat agar cultures maintained at 20° C. for 4–6 weeks. Portions of the culture were fed to snails, and the excreta collected and kept in a moist atmosphere at room temperature. The old oogonial and antheridial walls appeared unaltered by this treatment, and within a few days germination of a number of oospores was observed.

Oospores germinated by germ tubes, which sometimes terminated in a sporangium, or branched to form more than one sporangium. In many of the germinating spores varying degrees of thinning of the endospore prior to the emergence of the germ tube were observed. Fig. 1 (left) shows a germinated oospore with a partially digested endospore. In several instances, however, germination apparently occurred so rapidly that the germ tube penetrated the thick oospore wall. This can be seen in Fig. 2 (right), in which the constriction of the germ tube throughout the thickness of the wall may be noted.

A similar stimulation of germination has been observed in preliminary experiments with oospores of *Phytophthora cactorum*.

It is well known that snails secrete large amounts of cellulase. Whether the stimulation of germination obtained in these experiments is due to the activity of this enzyme on the oospore wall or to the action of micro-organisms present in the snail intestine is being investigated.

Tsunamis

THE term 'tidal wave' is often used for long, high waves which follow a major earth movement or intense atmospheric disturbance affecting the sea. This term is very misleading as the waves are only very rarely connected with tides, and so oceanographers have begun to use the Japanese word 'tsunami' for this phenomenon. It has been suggested, however, that this merely means 'tidal wave' in Japanese so that its use is no more logical.

This view is, however, mistaken; for although the word is used in Japanese in a colloquial sense to describe a tidal wave, the original roots of the word do not have any reference to tides. The word has not always been used in Japanese but has become part of the language in the course of centuries and is spelt by using Chinese characters called Kanji. Japanese words spelt in this way have evolved in rather a curious fashion; the sounds of the words are mainly original to Japanese, but the letters or characters had to be borrowed from the classical Chinese language spoken nearly two thousand years ago. Chinese characters denote short words rather than letters and so each has a definite meaning. On translation to Japanese, these characters can: (1) preserve the same meaning but become associated with a different sound, (2) have a similar sound but now a different meaning, or (3) remain more or less unchanged in sound and meaning. As some words are combinations of these short words, all three types can occur in one word. In the construction of new Japanese words, the last type is generally aimed at; Chinese characters with the appropriate meanings are found and then pronounced after the Chinese manner.

The word 'tsunami' appears to belong mainly to the first type. It consists of the two letters 'tsu' and 'nami'. The part 'tsu' has identical characters with the Chinese 'shin', which can have several meanings but of which only three—a ferry, a harbour, a beach or coast—have any reference to the sea. A survey of place-names suggests, however, that the sound 'tsu' must have been used in ancient Japanese for 'harbour', for there are examples like Tsu (Honshu), Abura-tsu (southern Kyushu) and Naniwa-tsu, which is the old name of a harbour in Osaka Bay. All these places are, or have been, harbours. The sound of the second part of the word, 'nami', has always been used in Japanese for 'waves'; but in Chinese the characters used to indicate the sound would be pronounced 'rou' (or 'lou') or occasionally 'ha', but the meaning is still 'waves'.

The most likely meaning of 'tsunami' is thus a harbour wave, which appears to be a not unreasonable appellation for a 'tidal wave' as these waves affect harbours but not ships at sea. It may be interesting to note that the Japanese for tide or a genuine tidal wave is 'chō-seki'.

FORTHCOMING EVENTS

Thursday, July 25

Royal Society of Tropical Medicine and Hygiene (at the Hospital for Tropical Diseases, 4 St. Pancras Way, London, N.W.1), at 7.30 p.m.—Clinical Meeting. Chairman: Brigadier J. S. K. Boyd, O.B.E., F.R.S.

Friday, July 26

Society of Chemical Industry, Food Group (joint meeting of the Food Law Institute of the United States, the Society for Analytical Chemistry, and the Association of Public Analysts, at the Royal Institution, Albemarle Street, London, W.1), at 10 a.m.—Conference on "The Control of Chemical Additives in Food".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Operational Research Scientists (with a good honours degree in engineering, physics, mathematics or statistics, the ability to handle data, to think objectively, and to exercise a high degree of imagination and initiative) in the N.C.B.'s Field Investigation Group, based in London, to study a wide variety of projects in planning, production and in human problems—The National Coal Board, Staff Department, Hobart House, London, S.W.1, quoting X/756/2/B (July 25).

Adult Laboratory Steward (with experience in the organization of laboratories, stores or workshops, and preferably some skill with hand tools and model making)—The Principal, Derby and District College of Technology, Normanton Road, Derby (July 27).

Assistant Lecturer (preferably with a special interest in some aspect of social geography) in Geography—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (July 27).

Demonstrator in the Department of Physical Chemistry—The Registrar, The University, Leeds 2 (July 31).

Head (with good qualifications, administrative ability, and the capacity to further the development of courses in the application of mathematics to industrial problems) of the Department of Mathematics, including Industrial Statistics—The Registrar, College of Technology and Commerce, Leicester (July 27).

Senior Lecturer in Electronics; a Senior Lecturer in Metallurgy; a Lecturer in Metallurgy; an Assistant, Grade "B", in Chemistry; an Assistant, Grade "B", in Biology; an Assistant, Grade "B", in Metallurgy; an Assistant, Grade "B", in Mathematics and a Lecturer in Physics—The Clerk to the Governing Body, Brunel College of Technology, Woodlands Avenue, Acton Hill, London, W.3 (July 27).

Zoologist (graduate in zoology of a British university) at the Dove Marine Laboratory—The Registrar, King's College, Newcastle upon Tyne (July 27).

Assistant Lecturer (with a qualification in bacteriology and suitable postgraduate experience) in Bacteriology—The Secretary, North of Scotland College of Agriculture, 41½ Union Street, Aberdeen (July 31).

Lecturer in Organic Chemistry—The Secretary of University Court, The University, Glasgow (July 31).

Lecturer in the Department of Electronics—The Registrar, The University, Southampton (July 31).

Research Assistant (with a good honours degree and some postgraduate experience in sedimentary petrology, or palæobotany, or stratigraphical work) in the Department of Geology, to work under the supervision of Prof. F. W. Cope, on a detailed study of the upper coal measures of North Staffordshire—The Registrar, University College of North Staffordshire, Keele, Staffs (July 31).

Dairy Chemist (with an honours degree in chemistry and preferably experience of dairy chemistry) in the Dairying Department (at Auchincruive), for investigational work and the supervision of routine analyses—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (August 1).

W. T. Henley Fellow (with a good university degree in electrical engineering or in physics), for research work in electrical engineering—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (August 1).

Biochemist (male or female, with an appropriate science degree or the A.R.I.C., or other approved qualifications) in the Pathology Department—The Group Secretary, Southport and District H.M.C., Promenade Hospital, Southport (August 3).

Chair of Education—The Secretary, The University, Exeter (August 3).

Physical Chemists (with an honours degree or equivalent, and experience in corrosion or a related field) at the Central Electricity Authorities' Research Laboratories, Leatherhead, Surrey, for work on corrosion problems arising in nuclear and conventional power stations—The Director of Establishments, Winsley Street, London, W.1, quoting Ref. N/296 (August 3).

Senior Lecturer or Assistant Lecturer in the Department of Physics—The Registrar, The University, Manchester (August 12).

Research Chemists (2) (with a university honours degree in science with chemistry or organic chemistry as major subjects together with some years of postgraduate research experience) in the C.S.I.R.O. Wool Textile Research Laboratories, Geelong, Victoria, Australia, to carry out investigations on chemical problems associated with the wet-processing of wool—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Ref. No. 462/99 (August 17).

Student for research on the kinetics of gaseous oxidation reactions—The Registrar, The University, Hull (August 17).

Junior Lecturer (young graduate in engineering or physics, interested in heat, light, sound and ventilation) in the Department of Applied Physiology—The Dean, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1 (August 30).

Lecturer (with an honours degree in engineering, an interest in research, and some experience in the fields of nuclear engineering and/or of the compression ignition engine) in Mechanical Engineering—The Registrar, The University, Edgbaston, Birmingham 15 (August 31).

Professor of Farm Management; a Professor of Agricultural Chemistry; a Professor of Chemical Engineering; and a Professor of Celtic Archæology—J. P. MacHale, Secretary and Bursar, University College, Dublin (September 15).

Assistant Professor (preferably graduate with soil science specialization and having Ph.D. degree or equivalent training) of Soil Science—C. F. Bentley, Department of Soil Science, University of Alberta, Edmonton, Alberta, Canada (October 31).

Director of the Commonwealth Institute of Entomology, London—The Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Bucks (October 31).

Analytical Chemist (male or female), for work on gas analysis of hydrocarbon mixtures by physical and classical methods—Prof. H. Ford, Mechanical Engineering Department, Imperial College, London, S.W.7.

Animal Attendant (with previous experience)—The Secretary, Royal Veterinary College, Royal College Street, London, N.W.1.

Assistant Experimental Officers (chemists, physicists, mathematicians, civil and mechanical engineers) at the Road Research Laboratory (D.S.I.R.), Harmondsworth, Middlesex, for varied and interesting work on materials, methods of construction, traffic and safety—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.195/7A.

Assistant Experimental or Experimental Officer in the Microbiology Unit to work on legumes and root nodule bacteria and/or microbial decomposition of grass leys—The Secretary, The Grassland Research Institute, Hurley, near Maidenhead.

Assistant Lecturer in Organic Chemistry—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8.

Assistant Lecturer or Lecturer in Pure and/or Applied Mathematics—The Secretary of the Trustees, Magee University College, Londonderry, N. Ireland.

Assistant Recordist (education to G.C.E. standard and preferably previous experience in electro-encephalographic recording) in the Department of Applied Physiology, Maida Vale Hospital, London, W.9—The Secretary, The National Hospitals for Nervous Diseases, Queen Square, London, W.C.1.

Chemist or Biochemist, Senior Scientific Officer or Scientific Officer grade, to study the uptake and metabolism of radioisotopes by plants, by field and laboratory work—The Group Recruitment Officer (823/34), Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Deputy Director; and a Lecturer or Assistant Lecturer on the Staff of the Computational Unit which is about to be set up and will be equipped with a Ferranti Mark II Mercury electronic computer—The Secretary of the Senate, University of London, Senate House, London, W.C.1.

Electrical Engineer (preferably with an honours degree and an elementary knowledge of feedback engineering) in the Plant Engineering Division, for development work having the primary objective of automating steelworks plant—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "E.7".

Geologists (with a first- or upper division second-class honours degree in geology) with the Government of British Guiana, for general geological mapping and mineral investigations in the interior of British Guiana—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.105/30/02.

Head (with high academic qualifications in mathematics, with teaching and research or industrial experience) of the Department of Mathematics—The Principal, Technical College, Queen Street South, Huddersfield.

Hospital Biochemist (with an honours degree, preferably in biochemistry or chemistry), to participate in research into the biochemical aspects of fungal diseases of the skin—The Group Secretary, Huddersfield Hospital Management Committee, The Royal Infirmary, Huddersfield.

Junior Lecturer in Entomology—The Dean, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1.

Librarian (with a working knowledge of at least one foreign language, and preferably experience of scientific literature)—The Secretary, Research Station (University of Bristol), Long Ashton, Bristol.

Mineralogist (with a first- or upper division second-class honours degree in geology, with specialization in mineralogy and some experience in X-ray crystallography) in the Geological Survey Department, Government of Tanganyika, to work chiefly in the Geological Survey Laboratories on the identification and study of minerals being investigated by the Department—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD. 105/8/04.

Physical Chemists and Metallurgists, for the study of problems of corrosion of metals in water and steam at elevated temperatures arising from development of new alloys for use in high temperature pressurized water reactors—The Group Recruitment Officer (830/2), Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Post-doctoral Research Fellow in Upper Atmosphere Physics, for investigations of the spectrum of the aurora and airglow in the PbS region—Dr. A. Vallance Jones, Department of Physics, University of Saskatchewan, Saskatoon, Saskatchewan, Canada.

Professor (Nuclear Engineer) in Applied Science, to take charge of a new course for highly selected engineering graduates leading to a Master's degree, to co-ordinate instruction in the several departments, to be responsible for setting up demonstration equipment, such as a subcritical assembly, and to teach the principles of nuclear engineering in at least one department—Dean H. G. Conn, Queen's University, Kingston, Ontario, Canada.

Research Assistants (2), for work on the action of gamma radiation on organic compounds and reactions—The Registrar, King's College, Newcastle-upon-Tyne.

GRIFFIN'S STATISTICAL MONOGRAPHS & COURSES

Edited by M. G. KENDALL, Sc.D.
Professor of Statistics in the University of London

This Series has been planned to meet the need for a form of publication, at moderate cost, which makes accessible to a group of readers specialized studies in statistics or special courses on particular statistical topics. Appearing in a standard cover, the text printing method used for each volume will suit the complexity or otherwise of the subject.

No. 1. *Just published*

MULTIPLE TIME-SERIES ANALYSIS M. H. QUENOUILLE, M.A.

CONTENTS: Preface — Introduction — Specification — Identification — Preliminary Investigation — Practical complications — Estimation — Significance and Goodness-of-Fit Tests — Practical Examples: U.S. Hog Series — List of Symbols — References.

108 pages. 8½″ × 5½″. 24s. net, Postage 6d.

EDUCATION FOR MANAGEMENT

A FEATURE of recent debates in Parliament on technological and on university education in Britain has been the attention given to training for management; and the emphasis placed on a broad general education, both in these debates and in discussions elsewhere, arises in part from the desire to secure a continuing succession of able administrators and managers both in industry and in the public services, competent to deal with the technical as well as the human issues with which they will be confronted. This concern has been equally manifested in many discussions and debates on technological change and on automation, and particularly in Parliamentary debates on nuclear energy and the Electricity Bill. There, however, the focus of attention was not so much on the educational aspect, as on whether the changes proposed in the structure of the electrical industry would limit the opportunities for its technical staff, and indeed whether this and other nationalized industries could offer the conditions and the opportunities which would attract and hold talent of the highest ability.

Although it is now generally recognized that it is of the utmost importance to ensure a sufficient supply of managers and administrators of the highest ability competent to handle the growing complexity of problems which confront the manager and the administrator to-day, the full implications are far from being appreciated. Quantitatively they were scarcely noted in the report on Scientific and Engineering Man-power in Great Britain last autumn, and the survey of graduate employment undertaken by Political and Economic Planning threw little light on this aspect. Yet, as Sir Edward Appleton noted in his Reith Lectures, to attract able young minds to such careers is an essential part of the problem, and the question of motive might well repay further study. Too much emphasis in this connexion could be placed on the scientific and technical aspects of management problems. There is a moral or altruistic appeal, which has attracted men of the character and intellect required into the professions and into the public service, and which might equally attract such men and women into industry if a little care were taken to show the satisfaction which can be found in co-operation and in tackling the intricate problems of labour relations, design, research and production which management may involve.

These are problems upon which the universities as well as industry should be thinking hard. They affect the content of university education as well as the extent of its expansion, though the fact that the manager and administrator could be drawn from arts graduates as well as from those in science or technology complicates the estimate of demand for particular categories. There is, however, welcome evidence that this is being done. Apart from recent references made to this matter by the chairmen of several leading industrial firms in addressing the annual meetings of shareholders, three recent books* have dealt with various aspects of the problem from what may be described as the employment side; and from the point of view of the educationalist, Dr. B. V. Bowden, while disclaiming any idea that the Manchester College of Science and Technology should prepare ordinary undergraduates for degrees in industrial administration, has set forth clearly the way in which a university department could assist, both in the provision of competent managers and in the study of the enduring difficulties which confront them.

Dr. Bowden suggested that there were six fields of teaching and study in which a university department of industrial administration could help. It should explain to undergraduates in science and engineering something of the social and managerial problems of productive industry. In particular, it could help the technically qualified student who had already entered industry, but who was attending courses at the college on a part-time basis. The third possibility lay in offering a short full-time course for rather older men who had already achieved a position of responsibility, but might be fitted for higher posts. The courses given at the Administrative Staff College at Henley represent a fourth approach to raising the standard of management and preparing men for positions of responsibility on policy-making boards. Then there were courses for foremen, though much of this work might be more suitable for the technical colleges. Lastly, he pointed out that no British university appears to be studying or preparing for the implications of automation, particularly those involved in the application of digital computers.

A survey of company executive development schemes, described in the first of the recent books on management alluded to earlier, was made by the Manchester College of Science and Technology jointly with the British Institute of Management. This survey originated from discussions in the education committee of the British Institute of Management on courses and facilities for education and training for management. Steps taken by individual companies for training their own staff within their own establishments have as great a contribution to make in developing the managers of the future as have courses provided by external educational associations, but whereas fairly full information is available about these latter courses, much less is known about what industry itself is doing. This pilot inquiry was undertaken to ascertain what proportion of companies in the chosen area did systematically provide for managerial succession, and to study in detail a few good schemes in various industries and in firms of various sizes.

---

* (1) Company Executive Development Schemes: a survey in North-West England made by the British Institute of Management and the Manchester College of Technology. Pp. vi+164. (London: Management Publications, Ltd., 1957.) 10s. 6d.

(2) Vitality in Administration. By Herbert Morrison, Basil Smallpeice, Sir Alexander Fleck, Sir Wilfrid Neden, A. D. Bonham-Carter and Major-General G. N. Russell. Pp. 78. (London: George Allen and Unwin, Ltd., 1957.) 8s. 6d.

(3) The Making of an Administrator. Edited by A. Dunsire. Pp. xv+125. (Manchester: Manchester University Press, 1956. Published on behalf of the Royal Institute of Public Administration, South West of England Regional Group.) 10s. 6d. net.

The statistical part of the survey was limited to firms employing more than five hundred people, and of the 112 firms interviewed about 36 per cent claimed that they had a definite training scheme; but the interviewer was sometimes left with an impression of vagueness regarding the assessment of managerial requirements and that he had been told what the firm felt it should be doing rather than what it actually was doing. Again, while 74 per cent of the firms claimed that personal audit by higher management was regularly practised, the investigator was again often left with a strong impression that the potential value of this feature was not appreciated. The survey well remarks that the real significance of this statistical study is that the proportion of firms claiming a definite training scheme, even if all such claims could be fully justified, is far too low for so vitally important a matter as ensuring managerial succession.

This position strengthens the argument of Dr. Bowden and others for greater attention to education for management outside industry as well as for co-operation between the universities and colleges of technology and industry. Clearly, for the present, over a large proportion of industry the improvement of management depends on the quality and interest of those entering industry, and on the provision of adequate opportunity for those within industry to return either to a university, a college of technology or to such an institution as the Administrative Staff College at the appropriate moment in their careers. It should be noted, moreover, that in the conclusions drawn from the case studies which occupy the greater part of the book, it is emphasized that, however well conceived a training scheme may be, its ultimate success depends upon the integrity, loyalty and leadership in the existing management. These are essential prerequisites of high morale, which is something to be deliberately evoked and maintained. The value of a sound executive development scheme may be nullified if the trainee has legitimate ground for thinking that management practice is falling far short of the standards which formed the basis of his training, and here the importance of learning by doing rather than observing is stressed. While the trainee needs to acquire a wide perspective of the organization in a short time, he is in danger of becoming frustrated by too long a spell without a job or responsibility of his own in which some initiative may be shown.

This emphasis on the importance of the active interest of the senior management in any such schemes is reflected in the six essays which the Royal Institute of Public Administration has published under the title "Vitality in Administration". In one of these essays, which are derived from a series of lectures which the Institute arranged in London in the spring of 1956, Mr. Basil Smallpeice, managing director of the British Overseas Airways Corporation, makes the bold claim that one nationalized industry at least possesses the vitality of administration which enables it to meet the challenge of intense and unceasing competition, and he suggests that the vitality of an administration is to be judged by the manner and speed with which it responds to the challenge of the changing situations that confront it. Sensitivity of perception, enabling the administration to recognize quickly the existence and nature of a situation calling for action; the ability to decide swiftly the precise action required; and prompt, energetic and efficient execution of the decisions reached are the three characteristics which Mr. Smallpeice considers as essential in any vital administration, and it is obvious that they demand qualities which are essentially personal and largely independent of a particular discipline or field of knowledge in which the administrator may have been trained.

It may be recalled that the Fleck Committee, which two years ago reported on the organization of the National Coal Board, was highly critical of the management of that industry, and was emphatic that, in the main, the industry should throw up its own leaders, and that positive measures should be pursued to that end. The Committee was clearly of the opinion that the industry had not been obtaining its due share of the nation's brain-power and executive ability, and its review brought out particularly the demand made on management for human understanding and for the moral qualities which leadership implies. Sir Alexander Fleck reiterates the emphasis laid in this report on the need for leadership, particularly at the highest level, in the essay on the pressure of technical change which he contributes to this series, and in which he illustrates how vitality in administration is secured and technical change is met in Imperial Chemical Industries, Ltd. Sir Alexander's concept of vitality is essentially creative: it is concerned with new concepts and new policies. The right choice of man, the establishment of mutual confidence, loyalty and discipline, involving close contact and collaboration between policy makers and executive, are primary factors in securing uniformly good management; the establishment of appropriate standards of performance for assessing the quality of management and ensuring that the benefits of a large organization are obtained are the qualities the exercise of which develops and maintains vitality.

Sir Alexander's stress on the need for constant vigilance on the human aspect rather than on organization is of the more interest to scientists in view of the high proportion of scientific and technical staff in Imperial Chemical Industries at every level: of the 7,800 male managerial staff, 5,800 are of this type, and the proportion is growing year by year. Sir Wilfred Neden, looking at human relations in industry as a whole, brings out the positive contribution which such enlightened and vital administration can make particularly in a time of technological change, as indeed was well shown in the study, "Technical Change and Industrial Relations", made by the Department of Social Science of the University of Liverpool. Mr. A. D. Bonham-Carter's essay on "The Motive Power of Higher Management" is concerned mainly with the means by which top management is kept at the highest efficiency, with particular reference to Unilever, Ltd., while in the last essay, entitled "The Challenge of Organization", Major-General G. N. Russell, general manager of British Road Services, describes the steps taken to forge the human links upon which effective communication really depends.

While these essays display very clearly the qualities which the administrator and the manager is required to exercise, and indicate that in some industries great care is already being taken in the selection of men for positions of high responsibility, they do not on the whole offer much guidance as to the training of a manager or administrator. It can be seen that a scientific or technical training is no bar to advancement to positions of the highest responsibility, and may indeed be a definite asset. Equally it is evident that the manager and administrator need a wide general education which develops not simply technical competence but also human insight, sympathy and judgment.

More light is thrown on the problem of education for management by the five essays delivered at Exeter to commemorate the centenary of the Northcote–Trevelyan report on the organization of the Civil Service, which have now been published under the title "The Making of an Administrator". Of these essays, one by Mr. D. K. Clarke, director of research at the Administrative Staff College, Henley, is concerned with educating the administrator and describes the way the Administrative Staff College works, emphasizing once again that to raise the level of administration it is not enough to add to the knowledge of the administrator: it is necessary to develop the man as a whole. In that essay, however, as well as in others, notably those of Sir Edward Bridges and Lieut.-Col. L. F. Urwick, support can be found for Dr. Bowden's views on the varied courses which universities or colleges of technology could offer; indeed, one valuable feature of all these books is their contribution to clarifying the function of the university in this field. The appropriate courses cannot be devised without clear ideas not only as to what is required but also when they are to be given, and at what stage in the student's career.

Sir Edward Bridges looks at administration from the point of view of the Civil servant, but his picture of the qualities required is valid for the administrator of any large organization, and although he believes that certain lessons can only be learnt on the job, he is less dubious than Sir Harold Banwell as to the possibility of administration being taught. Col. Urwick, on the other hand, is emphatic that there is a new body of knowledge greater than is commonly realized in industry or elsewhere which can and should be applied to problems of administration. Existing disciplines are not being applied to practical problems as they should, and he instances those which could be used in dealing with the individual task, the adjustment of the individual, the correlation of group-tasks, or the energizing of groups, so that facts are assessed objectively before conclusions are reached and judgments are based on facts rather than on prejudices or personal preferences. We have created an adaptive society, he argues, and we cannot live in it with the notions of political and social organization appropriate to a static and established society.

Col. Urwick agrees that leadership can only be learnt by experience and example, by being actually responsible for the work of others under wise and sympathetic guidance, and that this experience, in its initial stages, must come while the individual is young and impressionable. He believes that the demands upon administrative leadership are incomparably greater than they were a century ago, and that there is in consequence an irresistible drive towards larger units of control, with more numerous and multifarious relations with other units and institutions. Educational institutions are, in fact, failing in their task if they do not to some extent assist their students towards that more intricate social discipline which these larger units demand of those who participate in them.

There, indeed, is the core of the reason why technical colleges as well as universities cannot ignore the challenge which training for management offers them. No one pretends that even carefully and elaborately devised training can instil the spark of artistic genius which, in the good administrator, seems to be inborn. Nevertheless, as Mr. A. Dunsire remarks in the comment on the five lectures with which the book concludes, much can be done to produce a satisfactory level of competence in the young administrator in a reasonably short time, by making available the findings of previous practitioners about ways of doing and of acting that they have proved efficacious, and by providing wherever possible facts and figures to supplement the personal experience which he picks up on the job.

What stands out from these studies is the urgency and importance of the problem of improving the standards of management generally, and of ensuring that those with first-rate administrative ability have full opportunity to use and develop their gift. It is a field which offers large possibilities for co-operation between industry and the universities and technological institutions. Training methods may, as Mr. Dunsire notes, be considerably affected by new discoveries about administrative behaviour. While knowledge gained by personal experience may well remain the indispensable groundwork of the success of the administrator, we are far from having exhausted the means of supplementing it. There is a field for research here which university departments as well as the Administrative Staff College might well explore, and the question of training methods and courses in the broad field of management at various levels is one for which due provision must be made in plans for the expansion of British technological education in particular. Similarly, the expansion of university education must take account of the ways and means in our age by which the universities can continue to equip men and women able to face the problems of to-day, and to supply the leadership which is demanded by an age of rapid technological change. Even if judgment cannot be taught, it can at least be fostered, and the immense social importance of sound judgment would in itself justify every effort to encourage its development were it not also true that in fact certain university courses are already noted for their capacity to develop judgment, as well as the vision and understanding that the manager and administrator need in increasing measure to-day.

HOMINIDS AND 'HUMANS'

The Osteodontokeratic Culture of *Australopithecus prometheus*

By Prof. Raymond A. Dart. (Transvaal Museum Memoir, No. 10.). Pp. viii+105. (Pretoria: Transvaal Museum, 1957.) n.p.

Over the past thirty years the fossil Australopithecinae from the Early Pleistocene of South Africa, because of their remarkably primitive characters, have naturally provoked a good deal of discussion. The continued accession of much more complete skeletal material from limestone deposits in the Transvaal, however, has served to dispel earlier doubts which had been expressed about their taxonomic position; and the general consensus of opinion to-day has been fairly represented by the American palæontologist, Dr. G. G. Simpson, in a recent article (*Science*, April 26, 1957) in which he expresses the opinion that "the accumulated evidence is now overwhelmingly in favour of hominid affinities". But while the australopithecines may be accepted as early representatives of the family Hominidae, it does not necessarily follow that such terms as 'human' or 'man' can properly be applied to them. It is important to emphasize this distinction, for much confusion has unhappily been introduced into discussions on hominid evolution by the careless use of these colloquial terms. If it is agreed that the term 'man' should be reserved for those more advanced stages of hominid evolution characterized by the ability to fabricate tools, it is clearly not applicable to such primitive hominids as the australopithecines unless it can be demonstrated that they were tool makers.

The evidence which has so far been adduced for such a conclusion has either proved to be faulty, or, at the most, no more than suggestive. Prof. Dart, in his monograph on the bone breccia from the australopithecine deposits at Makapan, insists that it is much more than suggestive, for he claims that the rich assortment of animal remains from this breccia bears witness to an elaborate bone culture. But it is one thing to show, as Dart endeavours to do, that these fragments of bones and jaws could have been used as tools and weapons, and quite another thing to prove that they were used as such. Without doubt, Dart goes far beyond the legitimate limits of his evidence in propounding these claims, and it is a pity that this should be so, for his undue emphasis on this aspect of his studies obscures the more important parts of his monograph. It is unfortunate, also, that this over-emphatic style of writing must inevitably prejudice the reader against some of his quite legitimate inferences. The latter are concerned with the general nature and composition of the bone breccia. In the first place, Dart casts serious doubt on the suggestion that the accumulation of animal bones could have resulted from the activities of hyænas in occupation of the Makapan caves, or that they were carried in by porcupines. Here his argument is based on observations on the natural habits of these creatures to-day—there is no good evidence that they ever accumulate bony fragments of the kind, or in the number, found in the Makapan breccia.

Could the latter then be the relics of the hunting activities of the australopithecines? This is Dart's contention, and he seeks to test his conclusions by a most interesting analysis of the composition of the bone breccia in terms of the comparative frequencies of different skeletal elements of different animals. For example, he finds that 92 per cent of the total fragments recovered are those of Bovidae, and of 163 vertebral fragments of these animals 56 per cent are cervical vertebrae (as against 44 per cent of the thoraco-lumbo-sacral series). Moreover, about half the cervical vertebrae are the first and second (atlases and axes). From such data he infers that the bovid heads with a few of the adjacent cervical vertebrae must have been severed from the body before being carried off to the cave. Again, he finds great discrepancies numerically in the limb fragments—for example, 336 humeri as compared with 56 femora—and argues that this implies a selection of limb parts for the use which could be made of the bones as weapons. The quantities of bone flakes, many of them sharply pointed, he attributes to deliberate and systematic manufacture for use as flake tools, if only because there does not appear to be any other ready explanation for them.

Similar interpretations based on similar bone deposits have been put forward on previous occasions by archæologists. For example, Abbé Breuil, writing in the *Bulletin of the Geological Society* of China in 1931, supposed the bone flakes found in association with the remains of Pekin man at Choukoutien to be evidence of a bone-flake culture. In this case, however, some critics suggested that, before accepting such a conclusion, it would be well to examine bone breccias formed under conditions which would exclude all possibility of human agency, and no doubt the same criticism might be advanced in reference to Dart's conclusions. But if Dart, in pointing the way to the study of bone breccias by a statistical analysis of their composition, stimulates comparable studies on an extensive scale, his monograph will have served a most useful and important purpose. It may be, indeed, that the results of such comparisons will add support to his contentions that the australopithecines were sufficiently advanced to have established a veritable bone culture. For the moment, however, such a claim is surely premature.

W. E. Le Gros Clark

THE NEW PHYSICS

An Approach to Modern Physics

By Prof. E. N. da C. Andrade. Pp. ix+232+16 plates. (London: G. Bell and Sons, Ltd., 1956.) 25*s*. net.

Physics has advanced a long way since Andrade's book, "The Mechanism of Nature", first appeared in 1930. Then was a time of rapid advance, based on the new fundamental principles of the quantum theory, which had become sufficiently clarified in 1925 to bring order into much that had been chaotic. Now is a time of scarcely less rapid advance, relying for the most part on the same principles, no longer new, but still vital. Prof. Andrade's new book, "An Approach to Modern Physics", reflects the change. It is based on the earlier book, incorporating new material on such branches of physics as nuclear structure, elementary particles, and solids and liquids, in which considerable advances have been made in the past thirty years.

The scheme of the book is to single out a few of the basic conceptions of physics, and to devote a chapter to each. This approach gives a broad historical perspective of the development of physics without being circumscribed by chronology. The many interrelations between the ideas of the different chapters are admirably worked in. It starts and ends with philosophical chapters. "What is physics ?" is the question answered in the first chapter. The leading ideas of nineteenth- and twentieth-century physics —the nature of heat and of light, waves, electricity and atoms, quanta, the structure of the nucleus— are then introduced. The later chapters become more factual (for example, there is an account of the working of nuclear reactors), more concerned with reporting recent advances, and less reflective. The final chapter ("Uncertainty") is metaphysical, and an affirmation of a personal faith into which is interwoven a somewhat perfunctory discussion of the philosophical problems raised by quantum physics.

It is a pleasure to be able to read a popularization of physics so well thought out and written. It demonstrates that science and literature can still be combined in one work. The approach is often fresh, and the language always simple and graceful, without giving false impressions. The standard of excellence is by no means uniform, however, and one cannot resist the impression that the later chapters have received less polish than the earlier ones, letting in a few mis-statements and some rather facile judgments not in keeping with the standards of the earlier part.

I recommend the book both to the layman and to the student of science. The one will find in it a very readable account of the important concepts of physics; and the other will be made to see familiar ideas with a sharpened perception. M. H. L. PRYCE

THE HARVEY SOCIETY OF NEW YORK

The Harvey Lectures, Series 50 (1954–1955)

Delivered under the auspices of the Harvey Society of New York. By Dr. Vincent du Vigneaud, Dr. Richard J. Bing, Dr. J. L. Oncley, Prof. André Lwoff, Dr. Ephraim Shorr, Dr. George O. Gey, Dr. Bernard D. Davis, Dr. David Shemin, and Dr. Eugene L. Opie. Pp. viii+421. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1956.) 8 dollars.

THE Harvey Society of New York was founded fifty-two years ago with the object of fostering "the diffusion of scientific knowledge in selected chapters in anatomy, physiology, pathology, bacteriology, pharmacology, and physiological and pathological chemistry, through the medium of public lectures by men who are workers in the subjects presented". These laudable aims have been faithfully pursued, and realized, since the foundation of the Society, as testified by a complete list of the lectures in each year since 1905, which is included in the present volume. The Society has been admirably served by men of eminence in the various fields, and the titles of past lectures form an interesting reflexion of the climate of thought in the medical sciences over a period of great activity and progress. The collected lectures for 1954–55 illustrate the wide field covered by the Society, and in this series the emphasis rests to a considerable extent on metabolic and biochemical aspects, with considerable attention to bacteriological and cytological aspects. Specifically, the contents contain accounts of lectures on the hormones of the posterior lobe of the pituitary gland, heart metabolism, lipoproteins of human plasma, viral diseases of bacteria, metabolism of ferritin, continuous culture of normal and malignant cells, biochemical applications of bacterial mutants, porphyrins, and the conditions determining water movements into and out of cells. In addition, an address on the Harvey Society, on the occasion of its fiftieth anniversary, is included in this series. It would perhaps not be ungracious to note a slight geographical inaccuracy in the text, in which Lord Adrian is described as Master of Trinity College, Oxford. The format is attractive, there are adequate numbers of diagrams and illustrations, and although the material is, in places, highly concentrated, the spirit of the original lectures would appear to have been retained.

To the busy worker in a particular field, the accessibility in one volume of a wide variety of authoritative reports of recent work is an encouragement to wider appreciation of selected fields of effort, which is regrettably becoming progressively more difficult to realize. W. BURNS

LOVE AND SOCIETY

The Direction of Human Development

Biological and Social Bases. By Prof. M. F. Ashley Montagu. Pp. xi+404. (London: C. A. Watts and Co., Ltd., 1957.) 28s. net.

THE study of human behaviour and the structure of human societies, in ways that are in keeping with the requirements of scholarship and scientific inquiry, has always tended to be overshadowed by the speculations of those who feel themselves burdened with a mission for the reformation of the world around them or possessed with an insight which gives them a unique clue to the springs of human behaviour. Sometimes, indeed, the social 'scientist' becomes a propagandist or a prophet, and a muddle is thus created which may cause confusion in the minds of his colleagues and students. Another example of this kind is now presented to us in the work of Prof. Ashley Montagu, director of research, New Jersey Committee for Physical Development and Mental Health. His book is based on lectures given in 1944, in what has since become the Harvard University Department of Social Relations. In the course of delivering them, Prof. Montagu found that human nature became understandable to him for the first time; after ten further years of deliberation he has produced what is stated on the dust cover of the book to be an approach to "a scientific validation of the importance of love in all human affairs". His end is propagandist, but his method is pseudo-scientific; he faces himself with the task of distilling a value-judgment from scientific work and, needless to say, he fails to do so. He seeks to show that "human beings are born good", and he does so by defining 'good' as the "need to be loved and to love others".

There is, Prof. Montagu recognizes, nothing new in this formulation. What is new, according to him, "is that the meaning of love should have been rediscovered in the twentieth century by scientific means". But he proceeds, not by demonstration, but by circular definition. For 'love' is, for him, the "form of behaviour that contributes to the healthy development of both the lover and the loved", while 'health' consists in "the ability to love and the ability to work".

Furthermore, he faces himself with the problem that if men are born good, how is it that the societies in which they live (notably, according to Prof. Montagu, the American society) are so bad ? His answer is no more satisfactory than those of the array of philosophers who have broken their intellectual teeth on this in past ages. He argues that men are made bad by miseducation, adding a brief jeremiad directed against the American system. The social millennium might be produced, he suggests, if children were educated in the arts of human relations, in ways which remind one somewhat of the precepts of Mr. Dale Carnegie. "To produce loving human beings should be the primary purpose of education." But how are human beings, who have been miseducated into error, to educate their children into the way of truth, even when fortified by Prof. Montagu with the knowledge that "Love is God" ? That is a problem that can only be tackled by persons possessing a greater measure of sophistication than is at his command.

T. S. SIMEY

SUBJECTIVE PROBABILITY

Risk and Gambling

The Study of Subjective Probability. By Prof. John Cohen and Mark Hansel. Pp. x+153. (London: Longmans, Green and Co., Ltd., 1956.) 14s. net.

THAT 'probability is the guide to life' is now being taken seriously by psychologists. Ever since, and no doubt before, Sir Ronald Fisher's pronouncement that "inductive inference is the only process . . . by which new knowledge comes into the world" it might have been clear that inductive logic and probability theory should be serious candidates for forming the basis of learning theory. In fact, the major theories of learning have only introduced probability considerations as an afterthought, their preoccupation being with such concepts as drive, goal-seeking, reward and punishment. The experimental study of learning has—at least in animals—developed from physiology, and here the conditioned reflex of Pavlov has had a not altogether happy pre-eminence. It early became clear to students of behaviour that the classical Pavlovian situation, in which dogs were allowed only minimum freedom of movement and all distraction was avoided, could not afford a complete paradigm, where exploration was evidently so important.

The learning theorists of this period tended to regard Pavlovian conditioning as somehow the essential physiological basis of all learning, but requiring extra concepts, such as drive states, to describe the animal outside Pavlov's laboratory. J. B. Watson, of behaviourism fame, attempted to describe human learning in terms of chains of conditioned reflexes, all ultimately links from, and extensions of, a few innate and primary reflexes such as fear of falling and fear of loud sounds. Although influential, this failed if only because it could not explain increasing variety of effective stimuli ('stimulus generalization') for a given response, or learning by example.

If learning is regarded not as the building up of reflexes, or of 'links', but rather of conditional probabilities, then at once we have a simple formal language which seems appropriate for describing basic learning phenomena, including conditioning. The frequencies of 'input' and 'output' events can be described with the familiar probability calculus and we all know what we are talking about. We can also perhaps usefully compare animals and men with practical inductive machines, such as 'totes'. A. M. Uttley has built a special inductive machine which demonstrates many features of learning, and brings out some of the necessary logical and engineering conditions for a practical conditional probability inference device which might be accepted as a true 'learning machine'.

Once we have such a simple picture of learning as essentially gambling, then we may readily imagine an 'ideal learner', and this we may use as a reference for estimating the efficiency and the failures of actual animals, men and machines. Thus the study of subjective probability (or the probability or betting behaviour of men and animals making decisions) is highly important. The tragedy of the present book is that the live and fascinating issues in contemporary behaviour theory are not mentioned, and neither is the now large experimental literature. All that is given is an account of some experiments undertaken over the past few years by the authors themselves. Some of these are ingenious and apparently well planned, but they are given in a vacuum—a vacuum that might well be abhorred by Nature.

One of the most interesting experiments described concerns the behaviour of pedestrians at road crossings under various traffic conditions—an ideal life-and-death decision situation where the experimenter does not influence the situation since he can observe from some upper window—but the Road Research Laboratory has undertaken a long series of similar experiments, with most interesting results, and these receive no mention in this book. The book is perhaps intended for a non-serious audience, but the experimental data are given in numerous tables. These are very difficult to interpret or evaluate, for no statistical details are provided, mean values apparently being considered sufficient. The result is a lack of even tentative conclusions.

It is to be hoped that there may soon be a book summarizing the rapidly growing experimental literature, and relating this work with behaviour and learning theory and, perhaps, with the mathematical theory of communication. It is to be hoped that this new book might mention J. S. Mill, and Baye's axiom, as well as some of the experiments of at least B. F. Skinner, E. Brunswik, J. S. Bruner, W. K. Estes and J. W. Whitfield. One chapter might describe the changes produced in the old stimulus-response model by probability considerations.

R. L. GREGORY

The Birds of the British Isles

By Dr. David Armitage Bannerman. Illustrated by George E. Lodge. Vol. 6: Ciconiidae, Ardeidae, Phoenicopteridae, Anatidae (Part). Pp. x+326+26 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1957.) 63*s.* net.

In this volume Dr. Bannerman maintains the quality and interest of his text, and the pictures by the late George Lodge have their usual excellence. The first part gives an account of the storks and their allies, including only one common British bird, the heron, and one locally breeding species, the bittern. All the rest—herons and bitterns of other species, egrets, storks, glossy ibis and flamingo—have only a vagrant status in our area: a few are found in the nearer Continental countries, but the others are scarce or rare wanderers from southern Europe, or perchance from Africa, with one from America. Nevertheless, each is dealt with in full, the author drawing both on the literature and on his own extensive experience abroad. It may well be from some West African swamp that he has taken his true-to-life description of the squacco heron—inconspicuously buff at rest, but suddenly exploding into white as it opens its wings.

The second part of the volume covers a larger number of familiar species—albeit many of them only winter visitors—in the swans, geese and shelduck. The account of the barnacle goose in its native Arctic quotes at length (by permission) from Salomonsen's book on the birds of Greenland, a work to which many ornithologists in Britain do not have ready access; and the habits of other northern species are likewise fully described from various sources. The section on the shelduck includes an essay, contributed by Mr. R. A. H. Coombes, on the remarkable pre-moult migration which takes the majority of British adult birds to the sandbanks of the Heligoland Bight in late summer. LANDSBOROUGH THOMSON

Times and Places

By the late Harold Peake and Herbert John Fleure. (The Corridors of Time, Vol. 10.) Pp. xv+336. (Oxford: Clarendon Press; London: Oxford University Press, 1956.) 42*s.* net.

The author of this book has set himself a more than difficult task, and the measure of his success is the measure of his great knowledge and skill. The "Corridors of Time" consisted of a number of slim volumes, each devoted to a particular period of prehistoric development, written by the present author and the late Harold Peake. In the nature of the case, some volumes covered a larger geographical area than others, according to what archæological information was available at the time of printing. Of course, even then all that was known could not be included for lack of space, and the general picture given was what had grown up in the authors' minds. Much has happened since the first "Corridor of Time" was published—indeed, since the last saw the light of day. Not only has information come in apace, but also the general outlook on prehistory is rapidly changing.

In the first part of the present book Prof. Fleure makes a gallant attempt to bring a former volume dealing with the evolution of man and the cultures of the Old Stone Age up to date; the second half consists of a number of chapters devoted to the later prehistory of various geographical areas—South-West Asia, North Africa, the Mediterranean region, India, China and the Pacific. America is intentionally omitted and South African prehistory is barely mentioned. The result is a book which is very readable and, so far as it goes, one which gives an excellent summary of past ages over large areas in the old world. For the specialist, however, it is to be feared that the days of such a general survey are past; too much is now known to make such a work really possible. But for the intelligent amateur "Times and Places" is to be recommended. M. C. BURKITT

Physical Organic Chemistry

By Prof. Jack Hine. Pp. xiv+497. (London: McGraw-Hill Publishing Company, Ltd., 1956.) 67*s.* 6*d.*

This book gives a clear and detailed account of a field of work which has been attracting attention both from the theoretical and experimental aspects. Much of the work is modern and it is very useful to have such a summary of it. The experimental material is adequately surveyed, and there are many useful tables and curves. More than half the book deals with polar reactions, but free-radical reactions are included, and there is a separate treatment of four-centred reactions. The author has adopted the plan of treating a selected number of reactions in detail, but the concise discussion of others and the abundant references to literature make the book complete in its field. It is addressed to advanced undergraduates, graduate students, and industrial chemists, and it should fulfil its purpose in providing such readers with an intelligible account of an important aspect of modern organic chemistry. It emphasizes the mechanisms of organic reactions and the effect of structure on reactivity. Physical chemists will also find the accounts of the theory of acids and bases and general and specific acid-base catalysis of interest. This book can be recommended both to students and teachers as a very good survey of its field. The elegant style in which the equations and formulæ are set out makes the book pleasant to read.

J. R. PARTINGTON

Seeds of Life

The Story of Sex in Nature from the Amœba to Man. By John Langdon-Davies. Pp. xix+172. (London: C. A. Watts and Co., Ltd., 1957.) 12*s.* 6*d.* net.

His many friends will be disappointed by John Langdon-Davies's latest book. This, despite the fact that the theme is well chosen, the text well planned and written with that skill and fluency for which the author is well known. It is over the manner of presentation that the reader will be unenthusiastic. The book contains no diagrams, no photographs and no index. It may well have been the publisher's intention to present the absorbing story of sex in animals and man as a simple narrative; his wisdom in so doing without any visual aids to understanding can fairly be questioned. The purpose of a book of this kind should be to leave the reader with a sense of beauty and of wonder, and a body of knowledge. There is much evidence to show that one clearly labelled diagram conveys more information about the reproductive cycle in man than many pages of text to be found in a book such as this. Presumably, the form of the book has been dictated by economy; one fails to see how the publisher hopes to sell it in competition with the well-known cheap paper-backs which are copiously illustrated.

T. H. HAWKINS

THOMAS YOUNG AND THE THEORY OF DIFFRACTION

By Prof. A. RUBINOWICZ

Institute of Physics, Polish Academy of Sciences, Warsaw

> "He [Thomas Young] was one of the most acute men who ever lived, but had the misfortune to be too far in advance of his contemporaries. They looked on him with astonishment, but could not follow his bold speculations, and thus a mass of his most important thoughts remained buried and forgotten in the Transactions of the Royal Society until a later generation by slow degrees arrived at the rediscovery of his discoveries, and came to appreciate the force of his arguments and the accuracy of his conclusions".
>
> (H. Helmholtz, Popular Lectures)

WHEN Helmholtz[1] wrote the above words in 1868, he probably did not expect that after almost a century there would still be some of Thomas Young's scientific attainments which were not generally recognized. Of all the great discoveries we owe to Thomas Young and which have not been duly appreciated by succeeding generations, it was his diffraction theory which had to wait longest to become fully and entirely acknowledged.

Unfortunately, this fact seems not to have become sufficiently known. I was indeed greatly surprised to read, in a recently published biography which contained a deep appreciation of the work of this great discoverer and scientist, that Young's diffraction theory was untenable (Wood[2], p. 166), and that Fresnel's views must be regarded as superseding Young's explanation (Wood[2], p. 195). The same opinion is also expressed in almost all text-books on experimental physics. Only a few text-books on theoretical optics (see, for example, reference 3) give appropriate recognition to Young's contributions to the theory of diffraction. Since for some time past, and particularly recently in connexion with the preparation of a monograph[4] on the subject, I have been interested in the theory of diffracted waves, I should like to outline the origin of Young's ideas and their importance to the modern theory of diffraction.

Young's greatest contribution to diffraction theory lies in the fact that he was the first to give an explanation of the phenomena of diffraction on the basis of the wave theory of light. He started (Works[5], 1, p. 80) from the fact, known already to Newton, that an illuminated edge of a diffracting screen shines, and is thus a source of wave motion. He assumed that the diffraction phenomena arise as the result of the interference of two waves. The first, which may be termed the direct incident wave, is found at all points of space in which light is present according to the laws of geometrical optics, where it is described by the same wave function as in the case of undisturbed propagation of light. This wave motion is discontinuous across the boundary of the geometrical shadow, since there is a sudden change from light to darkness. The second wave motion, termed the diffracted wave, is represented by a wave diverging from the illuminated edge of the diffracting screen. Young[5] (1801) assumed that this wave motion is continuous everywhere, even across the boundary of the shadow.

This splitting of the light into two parts can be found already in Newton's[6] theory of diffraction, constructed on the basis of his corpuscular theory of light. The direct incident light is, according to Newton, due to the light corpuscles which, at any distance far from the diffracting edge, are not deflected by it, but move undisturbed along straight paths. On the other hand, the diffracted wave consists of the light corpuscles which pass in the immediate neighbourhood of the diffracting edge, and are thus deflected by it from their initial paths.

That Young's explanation suggests itself, so to speak, is shown by the fact that Fresnel[7] (1816), in his first paper on diffraction, independently hit upon it himself. However, already in 1816, in an appendix to that paper, Fresnel came to the conclusion that this explanation could not be upheld by the experimental facts. He therefore replaced it by a combination of the interference principle with Huygens's envelope principle. According to Fresnel, it may be imagined that the wave motion arises as a result of interference of secondary waves diverging from all points of a surface extending over the diffracting aperture. It is seen that a wave motion arising in this manner is continuous everywhere, and therefore across the boundary of the shadow too. As is known, Young himself finally came to the conclusion that Fresnel's views were superior to his own and communicated this to Fresnel in a letter dated October 16, 1819 (Works[5], 1, p. 393).

Young and Fresnel agree that the wave motion in the incident wave, as well as in the secondary waves, is given by an elementary law. If, however, we suppose that the motion of light must be described not by an elementary law, but by a partial differential equation, then we must regard only Fresnel's, and not Young's, point of view as justified. In the field of partial differential equations every discontinuity is caused by a physical factor; in the case of the scalar wave equation such factors are simple and double sources. But it is impossible on these lines to give a reasonable physical explanation for the discontinuity of the incident wave which appears at the boundary of the geometrical shadow in Young's theory of diffraction.

Thus it is understandable that when Kirchhoff[8] in 1882 set about building up a theory of diffraction based on the scalar wave equation, he quite automatically arrived at a development of Fresnel's ideas. The Kirchhoff–Huygens principle may be regarded as a matching of Fresnel's ideas to wave equation theory. In this manner the fate of Young's views was sealed for many years to come.

However, even in Kirchhoff's own works[9] we find, in connexion with the diffraction by a screen in the shape of a strip, the remark that "the position of the maxima and minima of the inner fringes (i.e., in the shadow of the strip) is the same as if they were caused by the interference of the rays diverging from the points at both edges of the screen. From this comes the first, indeed imperfect, attempt by Thomas Young to explain the phenomenon which we are considering".

A change in the appreciation of Young's views was brought about by the doctorate thesis of Eugen Maey[10]

(Konigsberg, 1893). Starting from Kirchhoff's theory, he established, in the special case of diffraction on a straight edge, the existence of a diffracted wave diverging from points on the edge. He proved theoretically and confirmed experimentally that the incident light is reflected by the straight edge into light cones, in the same way as from a straight cylindrical rod according to geometrical optics.

Next, in 1896, A. Sommerfeld[11], who studied at Königsberg at the same time, obtained an exact solution of the boundary problem for the diffraction of electromagnetic waves by a perfectly conducting half-plane, and in this way became the founder of the exact theory of diffraction. In accordance with Thomas Young's ideas, even the exact solution of Sommerfeld can be split into an incident wave, defined in the sense of geometrical optics, and a diffracted wave diverging from the edge of the screen. Sommerfeld formulated the problem of diffraction as a boundary problem in the field of Maxwell's equations. This explains why, in his theory, discontinuities at the boundary of the geometrical shadow could not occur, since there they would have to be interpreted as electric and magnetic charges and currents. Sommerfeld's diffracted wave must therefore compensate for the discontinuity of the incident wave at the boundary of the shadow, and thus must be discontinuous there, contrary to Young's assumption.

The question of the correctness of Young's views was clarified when it proved possible to split, in an exact way, the wave motion given by Kirchhoff's diffraction theory—that is, by his surface integral over the diffracting aperture—into an incident wave defined in the sense of geometrical optics and a diffracted wave diverging from the edge of the screen (reference 12). If Kirchhoff's diffraction theory is regarded as a precise formulation of Fresnel's ideas, then the transformation given must be regarded as a precise formulation of Young's views (cf. v. Laue[13]). Therefore, the views of Young and Fresnel are fully equivalent: neither can be given a privileged position. It is clear that the transformation of the Kirchhoff integral, as well as the Kirchhoff integral itself, provides a wave motion that is continuous everywhere in space except at the source of light. Hence, the diffracted wave in this case also must compensate for the discontinuity in the incident wave across the boundary of the shadow.

Using the traditional form of Kirchhoff's diffraction theory, the physicists restricted themselves to the calculation of Kirchhoff's surface integral for such special diffraction problems as diffraction at a slit, strip, circular aperture, or a circular screen. Since the diffracted wave is given by a line integral taken along the diffracting edge, and since a line integral is, in general, much easier to evaluate than a surface integral, it proved possible[14] to find the properties of the diffracted wave, and thus also to explain the nature of the diffraction phenomena for a very broad class of diffracting screens. Accordingly, light falling from a source on some definite segment of the diffracting edge may be regarded as reflected in reflexion cones. The diffraction phenomenon arises, at a given point of observation, as a result of the interference of the incident wave (if it exists there) with the diffracted waves diverging from those points of the diffracting edge which reflect the incident wave towards the observation point in question. These points on the diffracting edge, which we shall call 'active points', are so situated that the sum of the two distances from light source to active point and from active point to observation point has an extreme value. Thus the Fermat principle is valid here, just as in the case of reflexion by a plane in geometrical optics. It must be noted, however, that exactly as in the case of a wave reflected by a plane, the contribution to a reflexion cone comes not only from the active point itself, but also from the immediate neighbourhood of this point. We shall call this neighbourhood the 'active region' of the active point.

Since the diffracted wave must compensate for the discontinuity occurring across the boundary of the shadow, it is clear that its amplitude there must achieve the same order of magnitude as that of the incident wave. Calculation shows that the absolute values of the amplitudes of the diffracted wave on either side of the boundary of the shadow are equal to half the amplitude of the incident wave. In order that the discontinuity of the incident wave be compensated, the phases of the incident and diffracted waves must be opposite when approaching the boundary of the shadow from the side of the light cone, and must be equal when approaching from the side of the shadow. Therefore, the diffracted wave suffers at the boundary of the shadow a sudden change in phase of magnitude π.

In agreement with the fact that the diffraction phenomena are most marked at the boundary of the shadow, the amplitude of the diffracted wave falls off rapidly with the distance from the boundary of the shadow. The above-mentioned phase difference π between the two parts of the diffracted wave on either side of the boundary of the shadow is also maintained in these points of space.

If the part of the diffracting edge, containing the active region of an active point, is sufficiently straight, then the intensity distribution on the reflexion cone is given by the well-known Fresnel integral. This explains why it is met so frequently in diffraction theory.

Experiment confirms all these properties of the diffracted wave. That there indeed exists a wave motion diverging from the diffracting edge is confirmed by the shining of the diffracting edge when it is observed from the shadow or from the light cone. In the latter case, however, the eye must be protected against the direct incident light wave. A very elegant objective proof of the existence of the diffracted wave was given by Kalaschnikow[14] in 1912. He observed on a photographic plate the shadows of appropriately situated wires produced by the light of the diffracted wave coming from a diffraction edge. The positions of the shadows showed that the light responsible for them came from the diffracting edge.

The existence of active regions on the diffracting edge is corroborated by the experimental fact that, for a given point of observation, the only regions of the edge which shine are those about the points for which the above-mentioned sum of the distances has an extreme value[14]. Assume, for example, that the screen is circular and the light source is situated on the straight line perpendicular to the plane of the circle and passing through its centre. There may then be seen two shining points which are situated at each end of a diameter, and which correspond to the maximum and minimum values of the sum of the distances.

The existence of a change in phase of magnitude π between the parts of the diffracted wave in the light cone and in the shadow, respectively, can be confirmed by obtaining an image of the diffracting edge by means of the entire diffracted wave, with the direct incident light excluded. Since the parts of the diffracted wave cancel each other by interference, the diffracting edge appears as a dark line (reference 16). A suitable arrangement for such an experiment is afforded by Toeplers's method of striæ. This method makes it possible to eliminate the direct incident light and to observe the physical processes in the light of the diffracted wave.

All these are facts which are not easily explained from the Fresnel point of view, but which follow directly from Young's theory. They provide unequivocal evidence of the correctness of his hypothesis.

The last stage in the history of incorporating Young's ideas into the theory of diffraction phenomena has only begun. It will have to deal with the question of how far Young's diffraction theory can be justified by the exact theory of diffraction. The fact that the solution of Sommerfeld's diffraction problem is completely in accord with Young's theory is rather an exception. In general, we can merely expect approximate agreement. One may hope that this expectation will be fulfilled in the case of the diffraction of electromagnetic waves, at least for perfect or nearly perfect conductors. The integral equations which can in this case be given for the surface currents may be solved by approximation methods. The wave motion corresponding to this current distribution can be approximately represented[17] by a Fresnel integral, which can be regarded as an infallible sign of the existence of the diffracted wave.

The reality of the diffracted wave can thus be regarded as confirmed, both theoretically and experimentally. The structure of the diffracted wave, it is true, is not exactly like that imagined by Young. Nevertheless, it does not diminish Young's great achievement in the theory of diffraction, namely, to have shown that the diffraction phenomena can be explained at least in outline by the diffracted wave and the interference principle. Every great idea is subject to a process of development in the course of time. The fact that Young's idea could be developed without losing its original character is proof of its strength. The seed which Young has sown in diffraction theory has given a rich harvest.

SIR DAVID PRAIN, 1857–1944

By Dr. GEORGE TAYLOR

Director, Royal Botanic Gardens, Kew

THE centenary of the birth of Sir David Prain fell on July 11, and it is appropriate to recall the great services to botanical science of the fourth director of the Royal Botanic Gardens, Kew—a post which he held for nearly seventeen years. Prain's choice of a botanical career, which brought him such eminence, was largely influenced by Prof. J. W. H. Trail, who was professor of botany at Aberdeen. Trail had advised him during his arts course to register as a medical student and he did so without any intention at that time of proceeding to a degree. In 1878 Prain obtained the degree of M.A. with honours in natural science and for the next two years he was a schoolmaster at Ramsgate. In this period, with typical Scottish prudence, he saved enough money to enable him to return to his *alma mater* and to obtain full medical qualifications in 1882.

At this stage Trail again took a hand in shaping the destiny of his student by recommending Prain to Sir George King, superintendent of the Royal Botanic Garden, Calcutta, who happened to be on leave and asked Trail if he knew of any medical graduates with a bent for botany who would be inclined to join the Indian Medical Service. Thus it was that Prain entered the competition, was successful, and left to take up his medical appointment in 1885. This led eventually in 1898 to his succession to King as superintendent of the Calcutta Botanic Garden and also in the posts of quinologist, professor of botany at the Medical College in Calcutta, and director of the Botanical Survey of India.

So Prain followed the well-worn and traditional path from medicine to complete dedication to botany. Among his predecessors as head of the Calcutta Garden, each with a similar medical background, were his fellow-countrymen Roxburgh, Buchanan-Hamilton, Thomson and King. Prain held his offices in Calcutta for some seven years and, judged from the number of publications which he produced despite his heavy administrative duties, it was a period of great activity, though he did surprisingly little travel. He was able, however, to visit southern India and was also fortunate enough to collect around Khambajong in 1903 on the Tibetan plateau, where Sir Francis Younghusband was encamped while waiting to negotiate with the representatives of Tibet. On this visit Prain arranged for collecting to be continued by Col. Waddell and Capt. Walton, and the material, the first to reach Britain from the Indo-Tibetan marches, was extremely rich in new species. During his twenty years service in India, Prain did not allow administrative duties unduly to hinder his systematic studies on the flora, and his publication record during this period is most impressive. He had certain preferences, and the family Papaveraceae with the closely associated Fumariaceae engaged much of his attention. Other groups to which he had a predilection were the Scrophulariaceae, Labiatae and Leguminosae. Economic crops also interested him and he made notable contributions on Indian hemp, wheat, the mustards and pulses, and on the species of indigo.

Prain was appointed director of the Royal Botanic Gardens, Kew, on December 15, 1905. He took up his duties at a very difficult period when there was considerable discontent among the staff and much criticism about the state of the Kew publications. Before long he had eased the publication position and won the respect and esteem of his colleagues. As director he soon became immersed in committee work which, alas, is concomitant with the tenure of such responsible office. In spite of his considerable administrative load, Prain applied himself unsparingly to the continuation of his scientific work, and in this he was assisted by wise delegation of duties. He was not a familiar figure in the Gardens, preferring to be guided on horticultural matters by his able curatorial assistants. When he retired in 1922 the staff recorded their thanks "for his consummate tact and patience through years of unparalleled difficulty".

Naturally, with his distinguished record, many honours came his way. He was elected a Fellow of the Royal Society in 1905, president of the Botany Section of the British Association in 1909, president of the South-Eastern Union of Natural History Societies in 1912, and president of the Linnean Society in 1916. He was knighted in 1912 and was also honoured by the King of Sweden and the King of the Belgians. He received the degree of LL.D. from St. Andrews in 1911 and was awarded the Victoria Medal of Honour of the Royal Horticultural Society in 1912 and the Linnean Society's Gold Medal in 1935.

Though on retirement Prain shed his heavy administrative duties and many of the advisory responsibilities linked with the directorship, he readily assumed fresh and important obligations; some, such as membership of the Council of the Zoological Society and appointment as a trustee of the British Museum, seemed somewhat outside his normal interests, but these offices were a tribute to his sound judgment and understanding. The two World Wars dealt harshly with Prain. In the first his only son was killed near Armentières and in the second his home in the Caterham valley was so badly damaged by bombs as to become uninhabitable. After the death of his wife in 1942, his health declined and his appearances in London became rarer. He died on March 16, 1944 (see *Nature*, 153, 426; 1944). Sir David Prain is still remembered with affection and gratitude by some of his former colleagues, happily still working at Kew.

THE NEW RADIO RESEARCH STATION, DITTON PARK, SLOUGH

By Dr. R. L. SMITH-ROSE, C.B.E.

Director

On June 20, in the presence of a distinguished company, the new and permanent buildings of the Radio Research Station, at Ditton Park, Slough, Buckinghamshire, were opened by Sir Edward Appleton, principal and vice-chancellor of the University of Edinburgh. It was very appropriate that this ceremony should be performed by Sir Edward; first, because he has been very closely associated with the programme of the Radio Research Board for some thirty-six years; and secondly, because it was during his term of office as secretary of the Department of Scientific and Industrial Research that the post-war plans of the Department were drawn up. Among these plans was one which provided for the establishment of a Radio Research Organization which was to absorb and expand the work previously conducted in the Radio Division of the National Physical Laboratory. The plans being followed for this development, and a view of a model of the new building now formally opened, have been described in *Nature* (175, 921; 1955). The present contribution reviews briefly the historical development of the Radio Research Station, and summarizes its present national programme of research as a prominent part of a wider, international range of activities.

Historical

It was realized at the outset that the new organization would require a large area of ground on which to erect its aerial systems and conduct experimental work, in addition to the provision of suitable laboratory buildings for development work and certain types of investigation and measurements. After considering the merits of a number of sites, including some disused airfields and other fields in the vicinity of the new towns being developed around London, it was decided that the new organization should have its headquarters at Ditton Park, near Datchet. In many ways this was a very suitable choice since various types of experimental work had been in progress in these grounds for many years past.

It was after the formation of the Radio Research Board in 1920 that a search was made for a suitable field in which to conduct some experiments on the variation of the direction of propagation of radio waves. As the first chairman of the Board was Admiral of the Fleet Sir Henry Jackson, it was perhaps natural to find that the requirements could be met in the grounds of the Admiralty Compass Observatory in Ditton Park. So a start was made with experiments in radio direction-finding, to which were added, in succession, a study of field strengths from long-wave or low-frequency transmitting stations, investigations in atmospherics, the establishment of an ionospheric observatory, and the study of the modes of propagation of waves of high and very high frequencies.

From 1933 onwards, the Radio Research Station was regarded as an outpost of the Radio Division of the National Physical Laboratory, and while this Division was formally terminated in July 1952, the association of some of the staff with the National Physical Laboratory has continued in a gradually attenuated form until the new building became ready for occupation a few months ago.

Past Radio Research

In looking back over the past thirty-five years or so, we find that the staff of this station, together with research workers at universities associated with the Radio Research Organization, have made great contributions towards fundamental knowledge of the propagation of radio waves at all frequencies and under all conditions of transmission. A considerable series of publications described the results of the various investigations conducted under the auspices of the Radio Research Board before the Second World War. The work on direction-finding already mentioned was extended to cover a very wide range of frequencies and was applied to the location of the sources of atmospherics as well as of radio transmitters. The demonstration of the use of spaced aerial systems to give the highest attainable accuracy in direction and of the twin-channel amplifier with cathode ray tube presentation has formed the basis of industrial development and its practical application over the past twenty years. A radio sounding balloon was developed, which led up to the present method of sounding the atmosphere for meteorological purposes. In combination with a direction finder for following the course of the free balloons, the direction and speed of winds could be determined.

Intensive research was carried out on the factors which determine the variation of radio field-strength with distance from the transmitter; and the results obtained over a wide range of frequencies have formed the foundation from which has evolved much of the planning of communications, broadcasting and radio navigation services.

At the beginning of the International Geophysical Year, it is appropriate to refer to the Second International Polar Year of 1932–33, when radio was used for the first time as a tool for exploring the physical characteristics of the upper atmosphere. Under the auspices of the Radio Research Board an expedition, including members of the staff of the Station, went to Norway to investigate ionospheric conditions in northern latitudes. It was on their return that the need for regular soundings of the ionosphere became apparent, and there was established at Slough the first ionospheric observatory in the world. From a modest beginning with occasional soundings on special days, there has grown the organization existing to-day, in which a world network of one hundred or more observatories record conditions in the ionosphere at every hour of the day and night. Automatic equipment developed at the Radio Research Station is used at more than twenty of these observatories, six of which are manned by personnel either belonging to, or trained at, the Station. This continuous worldwide study of the ionosphere has provided considerable knowledge used by engineers responsible for the planning and operation of long-distance radio communication and broadcasting services. These services are also assisted by the regular supply of forecasts of the transmission conditions prepared at the Station six months in advance.

All the work referred to so briefly above culminated a few years before the War in the demonstration of the detection at the ground of echoes of radio waves reflected from aircraft. Following this, a group of staff from the Station formed the nucleus of the team which developed the technique of radar up to the stage at which it was taken under the wing of the Air Ministry. This team had the advantage at the outset of being able to apply quickly to a practical objective the techniques of pulse transmission and echo reception, and of direction-finding in both horizontal and vertical planes, which had already been developed for the purpose of fundamental scientific research.

Radio Research

The present programme of the Radio Research Organization is designed to assist in the solution of some of the problems which confront the various users of radio waves and radio-frequency techniques, whether for civil, military or industrial purposes. The major portion of the work for the past few years has been concerned with meeting the needs of the communication, broadcasting and radio navigation services by studying the propagation of radio waves along the ground and through the lower and upper atmospheres, and taking account of the various types of disturbance caused by atmospherics of natural origin and by interference due to electrical equipment. Other portions of the programme include an investigation of the physical properties of certain materials, such as semiconductors and ferromagnetic compounds, which are of special interest in the radio field. The measurement of power and field-strength, particularly in the upper bands of radio frequency, is also the subject of study and development.

Measurements are being made of the speed with which radio waves travel over land and sea, and the results correlated with geological structure and ground conductivity. The effects on wave transmission of irregularities in the ground and the presence of natural or man-made obstacles, such as hills, trees and buildings, are studied with a view of determining, for example, the probable service area of new television stations at increasingly higher frequencies.

The transmission of very short waves to distances beyond the horizon is largely determined by the vertical gradient and regularity of temperature, pressure and humidity in the lower atmosphere or troposphere. A long-term investigation is in progress on the relationship between radio and meteorological conditions in order to obtain the information required in assessing the performance of communication, broadcasting and television services; and especially for the future planning of such services, including radio links, at wave-lengths from a few metres down to a few centimetres.

The Radio Research Station is responsible for the maintenance of six observatories, two in the United Kingdom and four on British territory overseas, which make a continuous study of the characteristics of the ionosphere by the vertical sounding technique. The results obtained at these observatories and at some seventy-five others maintained by other countries are used in the preparation of forecasts of radio transmission conditions all over the world, six months in advance. These forecasts are used on a wide scale by organizations operating broadcasting, communication services and by air and marine navigation authorities.

The technique of sounding the ionosphere has recently been extended to points remote from the observing station by measuring the characteristics of echoes received by a combination of ionospheric reflexion and back-scattering from the ground at distances up to 10,000 km. (6,000 miles) or more. The study of the nature, time and direction of arrival of such echoes is greatly increasing our knowledge of the manner in which radio waves are transmitted to large distances around the world.

The scope of the various radio services is frequently restricted by the background of noise against which the signals have to be observed. Much of this noise is due to atmospheric disturbances arising in thunderstorms and lightning flashes. Measurements of the intensity of this noise are made in various parts of the world with a uniform type of apparatus designed at the Radio Research Station. The characteristics of this disturbing noise are also under continuous investigation in order to develop means of mitigating its effects. Other apparatus for locating the sources of these atmospheric disturbances has been developed and is used by the Meteorological Office to supply information on the position of storm centres for use in weather forecasting. An equipment for counting lightning flashes is under development in order to assist the meteorologist to supply information on the frequency and distribution of thunderstorms—information which is also required by the radio scientist.

Most of the apparatus required for these and similar investigations is of a highly specialized nature, and has been developed entirely at the Radio Research Station. In some cases, where the equipment is of interest to other users in Britain or abroad, a commercial firm has been assisted in reproducing it. Instances of such manufacture are the ionospheric recording equipment, which is entirely automatic in operation, the cathode ray direction finder for locating sources of atmospherics and the apparatus for measuring the strength of atmospheric noise on high and medium radio-frequencies.

In 1922, Admiral Sir Henry Jackson, chairman of the Radio Research Board, attended the first meeting of the International Scientific Radio Union (U.R.S.I.) in Brussels. In his report to the Board, he stated that all the suggestions which had been worked out in Britain as the basis of future radio research had been accepted internationally. This was the beginning of an association which rapidly developed on an international basis between the staff of the Department of Scientific and Industrial Research employed on radio research and their contemporaries in other countries engaged on similar problems. Many of these problems have involved close collaboration in, for example, the provision of programmes of transmissions, and the standardization of measurements on the ionosphere and of the terminology used in connexion therewith. Sir Edward Appleton attended the next meeting in Washington of the International Scientific Radio Union, of which he was president during 1934–52, and members of the radio staff of the Department of Scientific and Industrial Research have attended all subsequent meetings of the Union, and played a prominent part in promoting international research in scientific radio. At the present time, the writer is a vice-president of the Union, and chairman of Commission II dealing with "Radio and the Troposphere".

In a corresponding manner, the director and staff of the Radio Research Station have for many years past worked in co-operation with the Post Office delegation on the more practical problems studied by the International Radio Consultative Committee (C.C.I.R.), which is a technical advisory body of the International Telecommunications Union. Particularly in the field of radio wave propagation, much of the graphical and other results put forward by Britain have been adopted internationally as the basis for planning new radio communication and other services.

International Geophysical Year

The Radio Research Station is closely connected with the activities of the International Geophysical Year in the fields of the ionosphere and atmosphere. The observatories at Slough, Inverness, Singapore and Port Stanley are being provided with increased staff and facilities for conducting intensive programmes of measurement of heights, critical frequencies, absorption and drift in the ionosphere on the Regular World Days and Special World Intervals associated with the International Geophysical Year. Corresponding observations will also be carried out by a group attached to the Royal Society's expedition to Halley Bay on the Antarctic continent. Measurements of the level, characteristics and direction of arrival of atmospheric noise will be made at Slough, Singapore and Ibadan, Nigeria, where in addition intensive ionospheric observations will be made in co-operation with this Department.

In addition to this direct measurement work, the Radio Research Station has been designated as one of the four world centres for ionospheric and atmospheric noise data. Under this scheme about one hundred observatories associated with the western European nations will send to the Station tabulated and graphical results and also copies of the original ionograms. These will be exchanged with the other world data centres in the United States, U.S.S.R. and Japan, so that each centre will have a complete set of all the observational material obtained during the International Geophysical Year, and will hold this available for supply to research workers in any country in the region. The classification and indexing of the material will be co-ordinated by the secretariat of the International Geophysical Year in Brussels.

Publications and Staff

It has been evident for many years that the publication of papers and reports was not the only means by which the knowledge gained by those associated with the Radio Research Organization is to be made available to those anxious to apply this knowledge. A considerable dissemination is also achieved by the direct contact through committee or individual meetings. But over the years there have been demands for the loan or transfer of members of the staff to other organizations, where they become leaders of small groups or large departments as the case may be. The Radio Research Station has also been used both as a recruiting base and training ground for the staffs of the corresponding radio research organizations in Australia and New Zealand.

During the War, several members of the Department's staff served in succession as radio officers in the British Commonwealth Scientific Office in Washington, and several others have visited both the United States and Canada from time to time on special missions connected with research work of mutual interest to Britain and North America. More recently some members of the staff have been appointed to senior positions in government establishments and in industry in Britain and other countries. While these movements of staff may be somewhat disturbing to those left behind to continue the research programme, the demand for such experienced men must be regarded as a compliment, and a testimonial to the success of the Radio Research Station.

The scope for research in the field of telecommunications continues to expand, providing problems worthy of study by the ablest physicists and electrical engineers. Many of the techniques developed for the rapid communication of information are equally applicable to line or cable and to radio transmission: and there are many fruitful fields of research in which it is confidently expected that the new organization will play its part in giving direct assistance to trade and industry.

THE NATIONAL PHYSICAL LABORATORY

OPEN DAYS

THE National Physical Laboratory held two open days on May 22 and 23, instead of one as has been its practice for some years. More than two hundred and fifty exhibits, more than half of them new, were on view to 3,600 guests of the Laboratory who came from industry, the universities and government departments.

A problem of particular importance in the design of aircraft is that of instability in flight. The Aerodynamics Division has recently developed a general theory for wings oscillating at any frequency in a subsonic stream. A separate investigation of the aerodynamic forces on control surfaces at low speeds is in progress using the DEUCE high-speed digital computer which has been programmed to carry out the complex calculations. Experiments are under way to establish the theory and to investigate special cases, such as the transonic region, where the theory is inadequate. Equipment developed for measuring the oscillatory forces on model wings with trailing-edge flaps was demonstrated. As the inertial forces are very large compared with the aerodynamic forces, they are balanced against spring reactions in a system excited at its natural frequency by an electrical feed-back loop. The direct aerodynamic moments are derived from measurements of driving power and of the change in frequency due to the wind forces, while the lift forces are measured by capacity pick-ups supporting the oscillatory system. Oscillatory pitching and hinge moments have been measured in the subsonic range and the results agree well with theory.

Another aerodynamic oscillatory phenomenon is a type of control-surface oscillation called 'buzz'. Buzz has been experienced on some aircraft at speeds approaching that of sound, and can be so severe that failure of the control surface or its operating mechanism may occur. It is essentially an aerodynamically excited oscillation in a single degree of freedom, the flap vibrating with an angular motion about its hinge against the stiffness of its control circuit, usually with a frequency between 10 and 40 c./s. An experimental apparatus to reproduce buzz and to study the flow conditions in which it occurs was demonstrated in one of the high-speed tunnels. Schlieren investigations have shown that at least one buzz phenomenon starts when separation of the flow at the foot of the shock wave on the upper surface of the aerofoil takes place. High-speed ciné films of the interaction between flow and flap motion have been taken to assist in this study: some of these were on show.

The Control Mechanisms and Electronics Division displayed the new automatic computing engine (ACE) at present under construction. The design of this machine is a result of the experience gained from the ACE pilot model during its four years computing service at the National Physical Laboratory, and from the engineered version of the pilot model, DEUCE, at present in service. ACE will be a much more powerful computing tool than its predecessors because of its increased speed, larger memory and other additional functional facilities. In a typical day's working it will average 20,000 three-address operations per second: its speed is estimated at eight times that of DEUCE. Its large memory store, 1¼ million binary digits, will allow very complex problems, hitherto beyond the capabilities of computing machines, to be solved. The new ACE will soon be ready to execute its first test programmes.

The Division demonstrated a new digital plotting table. This has an accuracy of better than 0·01 in., and it plots at the speed of two points a second. It is a very simple design and embodies transistors and printed circuits. It is expected to satisfy an important need for a machine which will plot graphs from digital information on punched cards or punched paper tape.

The Electricity Division demonstrated how the National Physical Laboratory atomic clock is being used to check the drift rates of precision quartz clocks and the variation in the rate of rotation of the Earth. Compared with the atomic clock, the Earth gains in the northern hemisphere summer and loses in the winter, the maximum deviation being 40 milliseconds. Due to improvements in the electronics associated with the atomic clock, frequencies can now be determined with an accuracy of one part in 10^{10} in a measurement lasting only a few minutes. A new atomic clock designed to give even greater reliability, higher accuracy and increased simplicity of operation is under construction.

The most spectacular item on view was the new one-million volt testing transformer. This replaces three air-insulated transformers installed more than thirty years ago. It is a single unit rated at 700 kVA. designed to give a single phase output of one million volts when supplied at 1,200 volts. The winding is oil-immersed in a steel tank, the assembly weighing 55 tons. It is supported from earth on porcelain columns so that the tank can be connected to the centre point of the high-voltage winding—the columns can withstand half a million volts without flashover. The transformer is located in the open air, but the output can be fed into the main high-voltage laboratory through a porcelain wall-bushing 36 ft. long weighing 4 tons (Fig. 1).

The Light Division has collaborated with the Control Mechanisms and Electronics Division to develop a machine-tool monitor. The particular device demonstrated was a screw-cutting lathe controlled from a diffraction grating. A moiré

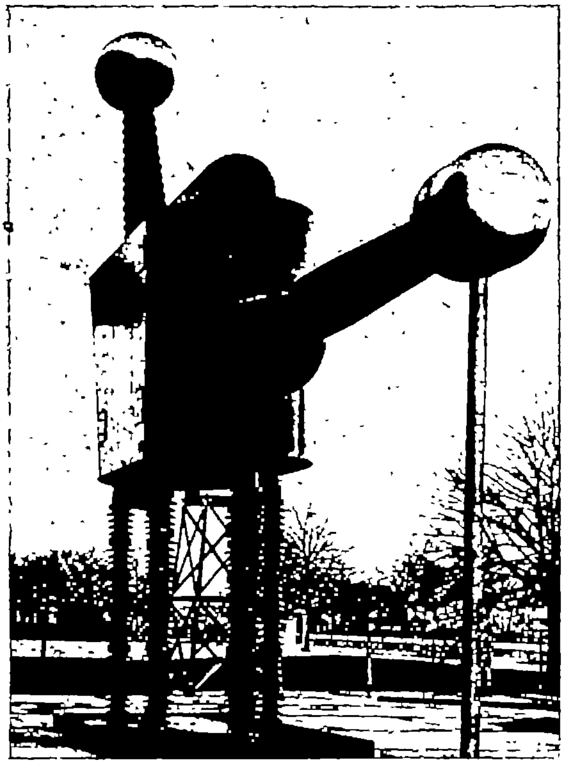

Fig. 1. New one-million volt testing transformer. Crown copyright reserved

system was set up using two diffraction gratings, one fixed and the other attached to the saddle of the lathe. The two gratings were chosen to have the same pitch as the thread being cut, so that one pulse per thread was produced from a phototransistor viewing the moiré pattern. In general the grating would be an integral multiple of the screw pitch. A potentiometer driven by the lathe spindle produced a sawtooth voltage which was sampled by the phototransistor. This sample voltage was obviously a measure of the angle of the lathe spindle at the instant when the pulse occurred. If the thread were perfect, this voltage would be constant; variations in it provided a measure of the errors of the system with micro-inch accuracy. It is intended to use the error signal to move the cutting tool relative to the saddle and so cut a nearly perfect screw thread. If this thread were then used as the lead screw in another monitored lathe, another even better thread could be cut and so on, improving the breed all the time. This is an attractive prospect for the production of machine tools with a new standard of precision.

The Light Division has also developed an automatic recording saccharimeter. This instrument matches two polarized beams using a photomultiplier and employs a Faraday cell as a compensator. The reading is taken off in terms of current and continuously recorded. Having no moving parts, its sensitivity is very high and very short path-length samples can be used.

The Mathematics Division demonstrated some of its powerful computing machines including DEUCE, a differential analyser and punched card equipment.

The Metallurgy Division has continued its research on the mechanical properties of single crystals of iron. The presence of 0·05 per cent nitrogen raises the yield and cleavage strength and increases the likelihood of brittleness, whereas nitrogen in the form of iron nitride has an even greater effect on yield strength and brittleness without affecting the cleavage strength. Using a radioactive technique, it has been found that the concentration of phosphorus at the grain boundaries, in an alloy of iron and 0·09 per cent phosphorus, can be fifty times as great as the grain interior concentration; the grain boundary layer may be thicker than has hitherto been supposed. This work may throw light on the question of temper-brittleness in low-alloy steels.

There have been important developments in micro-focus X-ray diffraction techniques. A new low-angle scattering camera has been built which focuses the X-ray beam by reflexion from two curved mirrors. This is being used to continue the study of progressive changes occurring in the low-angle scattering pattern when the specimen is subjected to increasing amounts of fatigue.

The Metrology Division demonstrated a 1,200-ton compression testing machine. This is to be used in the Division's programme for the development of precision load-measuring devices to extend the National Physical Laboratory standard for compressive loads to 1,000 tons. The new machine is hydraulically operated and can accommodate instruments of a maximum height of 80 in. on a 26 in. square platen. The machine will be used to standardize load-measuring units by building them up from 50-ton units initially standardized in the Laboratory's 50-ton deadweight standard machine.

For the first time the British national copy of the metre was on show. Like the International Prototype Metre, it is a bar of 90/10 platinum–iridium alloy of a special winged *X*-form which exposes the neutral plane and gives optimum rigidity in relation to the weight of the metal used. Last year, by arrangement with the International Bureau of Weights and Measures, it was re-polished and re-ruled with three fiducial lines about 0·005 mm. wide. These are disposed in the neutral plane so that the metre length is represented at both 20° and 0° C.

Following the development of a comparator for measuring the pitch errors of fir-tree root serrations (see *Nature*, 175, 1102; 1955), a similar device has been produced to measure the pitch errors in the roots of gas turbine disks. The tolerances on pitch are very close, so a high accuracy of measurement is required. The apparatus demonstrated measures to ± 100 micro-inches (± 2·5μ), very rapidly by comparison with a composite slip-gauge standard.

The Physics Division displayed two excellent examples of the application of simple scientific principles to complex problems. One of these was a thermal comparator for the rapid determination of thermal conductivity. This instrument is based on the well-known phenomenon that two substances may feel warm or cold to the touch depending on their thermal conductivities. Two balls are heated, one being pressed against the specimen to be tested. A differential thermocouple system measures the temperature difference between them after ten seconds; by comparison with a known specimen, this figure can be converted directly into thermal conductivity. The readings are affected by the surface finish of the specimens and this effect can be exploited to make the instrument function as a surface finish comparator. The other example of a novel use of a scientific principle was a demonstration of an investigation carried out on a 425-ft. chimney stack. In order to study its structural damping without having to wait for a suitable wind to excite oscillations, thrust units were attached to the top of the chimney and fired. The vibrations induced were measured in two perpendicular planes by means of piezo-electric accelerometers.

The Division's work on the establishment of standards of high pressure continues, and the new method of eliminating errors due to distortions of the pressure balances has now been used up to 3,000 atmospheres. This technique enables high pressures to be measured to an accuracy of a few parts in 100,000.

The Ship Division has extended its study of the conditions in which cavitation occurs from propellers to other hydrofoil devices like stabilizers and hydrofoil vessels. The Lithgow water tunnel has been modified for this purpose and force and acoustic measurements are now being made in it on a model of a fin for a ship roll-stabilizer. A new three-component balance has been developed and the model is mounted on this. Acoustic measurements are made with a hydrophone placed in a water-filled chamber in contact with a side window of the tunnel, the output being fed through an amplifier to a harmonic analyser for frequency analysis of the acoustic spectrum.

In order to calculate the motions of a ship in rough water, the values of certain coefficients are needed. The entrained water coefficient and the damping coefficient are functions of the hull shape and can be estimated theoretically, but there are few experimental results available to check the accuracy of the estimates. The Division is carrying out experiments to measure these coefficients for a number of different hull forms. The problem is simplified by restricting the motion to one plane and force-pitching the model in calm water by a system of rotating weights. A known cyclic variation of pitching couple produces an angle of pitch and a coupled vertical motion of the centre of gravity. Measurements are made of the angle of pitch, the heave of the centre of gravity and the phase relationship between these motions and the applied couple. These are recorded continuously throughout an experiment. The frequency of the applied couple is variable over a wide range and includes the resonant frequency. A. J. GARRATT

OBITUARY

Prof. Marinus Van den Ende

At the time of his death on June 4, at the early age of forty-five, Marinus Van den Ende was professor of bacteriology and dean of the Faculty of Medicine in the University of Cape Town, where he had earlier studied and graduated. He had come to England in 1937 with a John Lucas Walker Studentship, to work in the Department of Pathology at Cambridge, where Prof. H. R. Dean introduced him to me in the autumn of 1938. Even my short talk with him, at that first meeting, had made me glad to be able to respond to a suggestion that he might move to the National Institute for Medical Research, then at Hampstead, for the remainder of his second year.

Early in 1939, when he had been with us there for only three or four months, he had won such high regard from all by his character and personality, as well as by the brilliant promise which he showed in research, that a proposal to keep him, if possible, as a member of our staff was received with general enthusiasm. He felt at that time that his first duty was to South Africa; but he was able to obtain leave to extend his stay with us until the end of that year. In the last week of August the news of the Russo-German pact drove a number of us hurriedly home from the European Continent. Van den Ende had meanwhile married a young lady from South Africa, whom he had met again in London; but I found him now waiting anxiously for my return, in order to offer himself for the position on our staff which he had earlier felt obliged to refuse. He and his young wife had seen clearly what was coming, and both were eager to be with us in the coming world conflict. So he stayed throughout the War, doing splendid service, some of it involving serious personal risk.

Van den Ende first became an active member of a team working on methods for preventing aerial cross-infections in hospitals. Then, with Dr. Christopher Andrewes and the late Dora Lush, he was engaged in researches undertaken with some urgency, and having as their object the production of a safe and effective method of vaccination against typhus—an enterprise in the course of which every member of the team suffered, sooner or later, from an attack of the disease. Later he visited the armies in North Africa, with the rank of major in the R.A.M.C., to make a controlled trial of certain potential chemotherapeutic agents for the treatment of typhus. His final and most distinguished contribution to the war effort was the organization and direction, on behalf of the Medical Research Council and the War Office, of a special research unit, created on the Wellcome Foundation's farm estate at Frant, in Kent, for the production of a vaccine against the very dangerous 'scrub typhus', which the armies had encountered in the jungles of Burma and the Far East.

In 1945 he was free at last to return to Cape Town, where he was appointed professor of bacteriology, and where, in the years that followed, he made a rapidly growing reputation as a coming leader in research on the viruses, and as an influential teacher and an able organizer. He was on a visit to Melbourne some four years ago, to work for six months with Sir Macfarlane Burnet, when signs appeared of the illness which, though its progress was retarded by an operation and other forms of therapy, advanced to its inevitable end. With astonishing courage he used the intervals of temporary relief, between successive courses of prostrating treatment, to carry on his researches and his teaching, to such effect that his reputation in the world as a virologist continued still to grow, while he was persuaded further to accept the duties of dean.

Looking at what Van den Ende had thus achieved in a life cut short so early, and so marred by illness in what should have been its crowning years, his friends are left wondering what heights he might have attained had fate been kind, and mourning the loss to the world and to the community of science. Their sympathy goes to his widow, facing the situation with a courage worthy of him, and to their four children. H. H. DALE

NEWS and VIEWS

Textile Technology at Manchester:

Prof. W. E. Morton

PROF. W. E. MORTON, who has been head of the Department of Textile Industries at Manchester College of Science and Technology for thirty-one years, has been appointed vice-principal of the College and Arkwright professor of textiles, and will be taking up his duties at the beginning of the Michaelmas term. In November he is to receive the Warner Medal of the Textile Institute for his outstanding publications in the field of textile science and technology.

Prof. J. J. Vincent

MR. J. J. VINCENT, at present head of the Weaving Department at the Shirley Institute, has been appointed to succeed Prof. Morton in the chair of textile technology at the Manchester College of Science and Technology. Mr. Vincent graduated in mathematics at University College, London, and after obtaining his M.Sc., joined the staff of the Shirley Institute in 1929. During the War he was engaged in operational research for the R.A.F. and for a time was head of the Operational Research Section of Transport Command. In 1945 he returned to the Shirley Institute as head of the Weaving Department. He was made a fellow of the Textile Institute in 1950. When he started to work at the Shirley Institute, Mr. Vincent had the ambition to turn the design and setting of the loom from a craft to a science by applying mechanical principles and ideas underlying all engineering, and this idea can be seen in all his work. He has written papers, both alone and in association with others, on shuttle velocity, and under his influence 'systematic loom overlooking' has become a realized fact. In recent years, not only has he performed all the duties involved in the running of a large research department, but he has also contributed in detail to recent far-reaching developments that have occurred in the equipment for and the techniques of warp sizing—notably in the development of the 'Shirley' automatic size box and the use of sizing slurries. It can be confidently expected that under Mr. Vincent's direction textiles at the Manchester College of Science and Technology will continue to progress both as a science and as a technology.

Anatomy at Emory University, Georgia:

Dr. G. H. Bourne

DR. GEOFFREY BOURNE, reader in histology in the London Hospital Medical College since 1947, has been appointed professor of anatomy in Emory University, Georgia. He entered the University of Western Australia in 1928, studying comparative anatomy and histology, and soon turned his attention to the mammalian adrenal gland, on which he made a wide comparative and histochemical study. It was on this organ that he developed a histochemical technique for demonstrating vitamin C in tissues. Appointments in Australia included biologist in charge of experimental work, Australian Institute of Anatomy (1935), and the making of a survey for the Commonwealth Government of the nutritional value of Australian food (1937). Earlier, he had worked for a year in Melbourne under Prof. F. Wood-Jones.

A Beit Memorial fellowship took him to Oxford in 1938, where he was demonstrator in physiology (histology) and also held a Mackenzie Mackinnon research fellowship. During the latter part of the Second World War he was in charge of development of rations and physiological problems for Special Forces, South-East Asia. Later, with the rank of lieutenant-colonel, he was nutrition advisor to the British Military Administration, Malaya. He returned to Oxford in 1946 to continue research on wound healing and on localization of enzymes, particularly phosphatases, in hard and soft tissues. He has edited and written a number of books, "Cytology and Cell Physiology" (1942) and "Biochemistry and Physiology of Bone" (1956) being the best known. He will be chairman of the Anatomy Department at Emory University.

U.S. National Science Foundation:

Dr. E. A. Eckhardt

DR. ENGLEHARDT AUGUST ECKHARDT, formerly vice-president in charge of research for the Gulf Research and Development Co., Pittsburgh, Pennsylvania, has been appointed assistant director of the National Science Foundation, for the Division of Mathematical, Physical and Engineering Sciences. Raymond J. Seeger, who has filled the position in an acting capacity, will continue as deputy assistant director for the Division.

A physicist, Dr. Eckhardt is well known for his work in geophysics, ballistic measurements and building acoustics. He was born in Cedarburg, Wisconsin, and received his bachelor's and doctor's degrees in physics from the University of Pennsylvania. During 1908–17 he served as lecturer and assistant professor of physics at the University of Pennsylvania, except for a period during 1912–13, when he was awarded the Harrison fellowship from Pennsylvania to study at the University of Göttingen. Dr. Eckhardt was employed during 1917–25 as physicist in the Bureau of Standards. In 1925 he became assistant chief of the Research Department, Marland Oil Co., until 1928, when he joined the Gulf Research and Development Co. as assistant director of research, serving as vice-president from 1941 until 1953. During the Second World War Dr. Eckhardt served as deputy chief of the Physics Division and chief of its instruments section in the Office of Scientific Research and Development. Since 1954 he has been a consultant for the Gulf Company. Dr. Eckhardt was president of the Society of Exploration Geophysicists in 1939 and vice-president of the Geological Society of America in 1953.

British National Committee for Non-Destructive Testing

IN recent years the subject of the non-destructive testing of materials has achieved great importance, and at the beginning of 1957 a combined appeal was made by a number of societies to the Joint Committee on Materials and their Testing to foster the establishment of a National Committee to act as a focus in the United Kingdom for interest in the principles and techniques of non-destructive testing. The Joint Committee accordingly set up a sub-committee to examine this request and, as a result of its recommendations, the Joint Committee has approved the constitution, terms of reference and rules for a committee which will be known as the British National Committee for Non-destructive Testing. Membership of the British National Committee is open to institutions or societies with an interest in non-destructive testing: the subscription is 5 guineas per annum. Each member society will be asked to nominate a representative who would take part in meetings of the Committee. Applications, for the time being, should be made to the secretary of the Joint Committee on Materials and their Testing, Mr. R. Main, at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1.

Society of Instrument Technology

The Society of Instrument Technology is setting up a special section devoted to data-processing systems. This section will hold its first meeting in London on October 10, when a paper on "A System for Handling Wind-Tunnel Data" will be presented by J. F. M. Scholes, of the Royal Aircraft Establishment, Bedford. Further meetings will be held on November 14 ("A Digital Plotting Table", by J. Morrison, of Dobbie, McInnes, Ltd.); January 28 ("Digital Codes and Coding", by M. P. Atkinson, of the National Physical Laboratory); and on April 29, when a joint meeting on "Scanning and Logging", with papers by D. H. Whiting and J. Dunkley, of Imperial Chemical Industries, and J. Churchill, of Sunvic Controls, Ltd., has been arranged.

Initial emphasis will be on systems for handling experimental data, and for industrial monitoring and control. The section will be concerned with system design as well as with the detailed design of equipment; it will also deal with the use and organization of systems and with design-study work. The literature on data-processing techniques and application is scattered and much existing knowledge remains unpublished; one of the section's first tasks will be to obtain papers that review the present stage of development, for publication in the quarterly *Transactions* of the Society. Membership of the section is open to all members of the Society, who may also join the other special group, the Control Section. Further information can be obtained from the Secretary, Society of Instrument Technology, 20 Queen Anne Street, London, W.1. The secretary of the Data-Processing Section is Mr. W. T. Bane, 137 Kenilworth Court, London, S.W.15.

Australian Biochemical Society

The Australian Biochemical Society was founded in 1955 under the presidency of Dr. M. R. Lemberg. Its objects are simply the advancement of the science of biochemistry. The first annual conference was held in Sydney in 1956. At the second conference, held at the University of Melbourne during June 5–8, one hundred and fifty members from all parts of Australia attended, and the fifty-three papers presented evoked stimulating discussion. The papers covered a wide variety of topics; the general quality of the work indicated that Australia has undoubtedly kept pace with modern developments and is, in fact, among the leaders in some important fields of biochemistry. University, government, industrial and independent research institutions were well represented in the list of original contributors. A special evening lecture entitled "Phenyl Thiohydantoins in Protein Analysis" was given by Dr. Pehr Edman, formerly of the University of Lund, Sweden, and recently appointed John Holt director of biochemical research at St. Vincent's School of Medical Research, Melbourne. Another evening session was devoted to a general discussion on the role of the clinical biochemist and the organization of biochemistry in hospitals. Prof. V. M. Trikojus, Melbourne, was re-elected president for 1957–58.

Finance for Research on Wool

In the debate in the House of Commons on July 11, when the Draft Wool Textile Industry (Export Promotion Levy) Order, 1957, and the Draft Wool Textile Industry (Scientific Research Levy) Order, 1957, were approved, the Parliamentary Secretary to the Board of Trade, Mr. F. J. Erroll, explained that the purpose of the latter Order was to increase the yield of the research levy from about £155,000 to about £200,000; it is also intended to make some minor changes in the range of persons liable to pay the levy in order to bring it more into accord with present conditions and current developments in the industry. Mr. Erroll said that the additional money is required for capital expenditure by the Wool Industry Research Association and to meet increased costs since the levy was introduced; further, the Wool Textile Research Council also wishes to increase its research grants. In welcoming the two Orders, Mr. H. Rhodes expressed the opinion that methods of research used in the textile industry need re-casting and that there is too much duplication of effort. Research associations, he said, are spending small amounts on the same work because there is not enough liaison. He suggested that the original conception of research, as outlined when the Department of Scientific and Industrial Research was established, is now obsolete and that there is too much complacency. Problems common to the whole range of the textile industry should be investigated in one place with adequate resources, and the research stations should continue their day-to-day work for the firms they serve.

"Chymia"

The publication of "Chymia", an annual devoted to the history of chemistry, will be resumed in the spring of 1958 with Vol. 5. The publication is now sponsored jointly by the Edgar Fahs Smith Collection of the University of Pennsylvania and the Division of the History of Chemistry of the American Chemical Society. The editor-in-chief is Henry M. Leicester, College of Physicians and Surgeons, San Francisco, California, to whom all articles for publication, which must be in English, should be submitted.

University Interchange

The British Council has issued a report on "University Interchange between the United Kingdom and other European Countries, 1948–56" (pp. 56. London: The British Council, 1957). The report traces the development of certain schemes which the United Kingdom has undertaken in order to foster interchange visits between members of British universities and those of other European countries. Among these is the scheme for arranging short visits for university teachers; during the period under review 580 visits were received from foreign scholars, while 405 members of British universities went overseas. More than one-quarter of these were from the University of London; the four Colleges of the University of Wales sent one between them. So that interchange would not take place merely between scholars of established reputation, provision has been made to enable young workers engaged in original research to visit colleagues engaged in similar work in other countries. At present this scheme involves interchange between the universities in the United Kingdom, Belgium, France, Germany and Yugoslavia; it is hoped to include other countries in the scheme very shortly. Of the twenty-four British research workers who visited European universities one-sixth were from Oxford; not one came from Sheffield, Manchester, Liverpool or Edinburgh. The report also contains details of arrangements for longer teaching visits which are to begin in the academic session 1957–58, postgraduate scholarships, and the various awards by international bodies.

Marshall Aid Commemoration Commission

THE third annual report of the Marshall Aid Commemoration Commission (pp. 8. Cmnd. 167. London: H.M. Stationery Office, 1957. 6*d*. net) covers the year ended September 30, 1956, the first academic year in which a full quota of Marshall Scholars consisting of two groups selected in 1954 and in 1955 have been living in the United Kingdom. The work of the Commission has been directed mainly to making the best arrangements possible to enable these students to proceed with their studies and to selecting a further group of scholars to take up courses in British universities in October 1956. A list of these twelve scholars-elect is included in the report. Of the twelve scholars selected for the original awards, seven completed their tenure at the end of the academic year 1955–56, and of these two gained a Ph.D., one an M.Sc.(Econ.) and three a B.A. (one with first-class and two with second-class honours). The one who failed to graduate is being allowed to submit his M.A. thesis in a revised form at a later date, and the remaining four are to continue as students in British universities in 1956–57, three with extensions of their scholarships by the Commission. The remaining scholar had to resign his award for family reasons at the end of his first year. The Commission, while arranging for the proper reception of each group of scholars arriving in Britain, has not felt it necessary or desirable to organize an 'orientation programme' for the party as a whole, but has sought to encourage the newcomers to settle in as soon as possible at their several universities. The Commission acknowledges with gratitude the offers of hospitality to Marshall Scholars by various bodies, such as the English-Speaking Union and the Dominions Fellowship Trust. The Commission is studying the problem of payment of fares of candidates summoned for interviews, with the view of finding some solution which will not upset the distribution of awards between different areas in the United States, but which may prove less expensive in travel costs than the present system. All applicants continue to express strong preference for the Universities of Cambridge, London and Oxford, and in future they will be required to state a second preference elsewhere.

Fresh Water from Salt Water

PRESENT methods of and future prospects for preparing fresh from salt water have been reviewed by D. Neville-Jones, of the Department of Scientific and Industrial Research (*Colonial Plant and Animal Products*, 6, No. 1; 1956). In the near future there is every prospect that electrodialysis will prove the cheapest process for preparing fresh water from salt waters containing four or five thousand, and possibly eight or nine thousand, parts per million of salt. For waters containing more salt than this, and particularly with sea water, some form of distillation remains the only process which can at present be offered with confidence. In an area of high fuel cost, where a compact and self-contained plant is required, the choice would probably lie with vapour compression distillation. Solar distillation may be useful for the provision of small quantities of drinking water in isolated areas of high fuel cost where sunshine is fairly abundant.

Hydraulics Research

SEVENTY years ago Osborne Reynolds was conducting his classical experiments into the behaviour of models of tidal estuaries. Ten years later the first permanent river hydraulics laboratory was set up at Dresden. This was followed by a series of other large laboratories in Germany, the United States, India and Holland. Just after the Second World War, Britain was the only major country which practised hydraulic engineering on a large scale with no adequate laboratory as judged by international standards. In spite of this, valuable work was done, notably at the University of Manchester and the Imperial College of Science and Technology, London. In 1946 a Hydraulic Research Board was set up to organize work on loose boundary hydraulics on a national scale. A site for a laboratory was acquired at Howbery Park, Wallingford, in 1949 and was partially occupied in 1951. This laboratory, the Hydraulics Research Station of the Department of Scientific and Industrial Research, came into full use at its present stage of development last year. This point in the progress of the Station was marked by a visit by H.M. the Queen in November 1956.

The work of the Station during 1956 is recorded in its annual report, "Hydraulics Research 1956" (Report of the Hydraulics Research Board with the Report of the Director of Hydraulics Research. Pp. vi+54+12 plates. London: H.M. Stationery Office, 1957. 4*s*. 6*d*. net). Although the Station was intended for the study of loose boundary hydraulics, it has, in fact, undertaken work connected with other branches of civil engineering. Such work includes the action of sea waves on walls and in harbours, flood-relief schemes and testing of spillway designs. Roughly one-fifth of the effort of the Station is devoted to background research. This is partly exploratory work into loose boundary problems, such as the action of sea waves in scouring and silting beaches, and partly basic research, much of which is done in conjunction with university departments.

Citrus Fruits in Assam

CULTIVATED and wild forms of citrus have been known in Assam from ancient times; indeed, their abundance and diversity are such as to suggest that this region may have been a centre of origin and dispersal of some of the species and varieties. Under the auspices of the Indian Council of Agricultural Research, S. C. Bhattacharya and S. Dutta have produced a comprehensive monograph, with many excellent plates in colour, entitled a "Classification of Citrus Fruits of Assam" (Indian Council of Agricultural Research. Scientific Monograph No. 20. Pp. vi+110+84 plates. Delhi: Manager of Publications, 1956. Rs. 34; 52*s*.). Like other workers in this field, the authors have recognized the acute nomenclatural difficulties and the need for more systematic and other work, the more so as natural cross-pollination has resulted in the production of new forms adapted to the varied environments which the region affords. The present work is based on extensive collections, on long and intimate personal experience on the part of the authors of all the major citrus-growing areas in the hills and on the plains, together with wild specimens from the forest tracts, and on the creation and maintenance of a living museum of specimens, the latter affording materials for detailed studies. The classification adopted is based on standard treatises, but it has been broadened to accommodate the abundant materials found in Assam and, at this stage, is admittedly empirical. In all, some sixteen main species are enumerated.

Transmission of Raspberry Mosaic Viruses to the Strawberry

The disease known as raspberry mosaic is caused by a combination of two viruses, referred to as rubus yellow-net and black raspberry necrosis. In a recent study, R. Stace-Smith and F. C. Mellor (*Canadian J. Bot.*, 35, 287; 1957) have attempted, by means of the leaf-grafting technique, to transmit the two component viruses of raspberry mosaic, separately and in combination, to three strains of *Fragaria vesca* L. Only the rubus yellow-net virus was transmitted to the strawberry and it induced severe symptoms. Neither the raspberry aphid, *Amphorophora rubi* Kalt., nor the strawberry aphid *Pentatrichopus fragaefolii* (Ckll.), transmitted the yellow-net virus from raspberry to strawberry, although *A. rubi* was able to transmit the virus from strawberry back to raspberry.

Scientific Instrument Manufacturers' Association: Officers

Mr. P. Goudime, managing director of Electronic Instruments, Ltd., has recently been elected president of the Scientific Instrument Manufacturers' Association for the year 1957–58, in succession to Mr. G. A. Whipple, chairman and managing director of Hilger and Watts, Ltd., who now becomes a vice-president. Mr. R. Barrington Brock, director of Townson and Mercer, Ltd., has been elected vice-president (president-elect). Other officers for 1957–58 are: *Hon. Secretary*, Mr. L. A. Woodhead (Cossor Instruments, Ltd.); *Hon. Treasurer*, Mr. P. J. Ellis (R. B. Pullin and Co., Ltd.). Representing Sections of the Association are the following new members of the Council: Optical, Mr. G. C. Ottway (W. Ottway and Co., Ltd.), Mr. P. D. Scott Maxwell (Cooke, Troughton and Simms, Ltd.); Surveying and Navigational, Mr. R. Broadbent (Sperry Gyroscope Co., Ltd.); Electronic, Mr. A. W. Jones (Fleming Radio (Developments), Ltd.); Nucleonic, Mr. H. A. Luss (Isotope Developments, Ltd.); Northern Area, Mr. A. Howarth (Fielden Electronics, Ltd.).

The Night Sky in August

Full moon occurs on August 10d. 13h. 08m. U.T., and new moon on August 25d. 11h. 32m. The following conjunctions with the Moon take place: Aug. 4d. 21h., Saturn 0·2° S.; Aug. 27d. 17h., Jupiter 5° N.; Aug. 28d. 01h., Venus 3° N. In addition to these conjunctions with the Moon, Mars is in conjunction with Regulus on Aug. 6d. 15h., Mars being 0·7° N., and Venus with Jupiter on Aug. 22d. 15h., Venus being 0·5° S. Mercury is too close to the Sun for observation during the month. Venus sets about an hour after the Sun, and will be visible as a bright object low in the west just after sunset. Mars and Jupiter are too close to the Sun for observation. Saturn sets at 23h. 55m., 23h. 00m. and 22h. 00m. on August 1, 15 and 31, respectively; it is stationary on August 12, and afterwards moves eastwards among the stars. The stellar magnitude of Saturn is + 0·7 and its distance from the Earth on August 15 is 900 million miles. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Aug. 5d. 20h. 13·9m., ξ Oph. (*D*); Aug. 6d. 20h. 33·9m., 15 Sgr. (*D*); Aug. 19d. 2h. 42·5m., 163 B. Tau. (*R*). *D* and *R* refer to disappearance and reappearance, respectively. The Perseid meteors are active during the first two weeks of August, but conditions are very unfavourable for observation.

Announcements

Dr. D. T. A. Townend, director-general of the British Coal Utilization Research Association, and Dr. A. C. Monkhouse, acting director of fuel research in the Department of Scientific and Industrial Research, have been appointed to the Fuel Efficiency Advisory Committee in succession to the late Dr. G. E. Foxwell and Mr. W. L. Boon.

Dr. William Railston, a principal lecturer in physics at the Royal Military College of Science, Shrivenham, is to be seconded as scientific and technical adviser to the Commonwealth Relations Office with special responsibility for the scientific problems of the Colombo Plan. The appointment is for eighteen months. He will be based in London, but will make visits to India, Pakistan, Ceylon and other eastern countries.

A special one-day course on "Safety and Health in Welding", intended for nurses in industry and safety officers, has been organized by the Institute of Welding, to be held in London on October 12. Inquiries should be addressed to the Secretary, Institute of Welding, 54 Princes Gate, London, S.W.7.

A Faraday Society Discussion on "Interaction in Ionic Solutions" is to be held in the University Laboratory of Physiology, South Parks Road, Oxford, during September 17–19. There will be three sessions, devoted to the general theory of electrolytes, incomplete dissociation, and ion-solvent interaction, respectively. All inquiries should be addressed to the Assistant Secretary, Faraday Society, 6 Gray's Inn Square, London, W.C.1.

The eighth Conference of the Medical Group of the Institute of British Photographers will be held at the Royal Infirmary, Manchester, during September 20–22. It will be opened by Mr. Robert Newell, dean of Postgraduate Medical Studies, Manchester. This Conference is open to anyone interested in medical illustration. Full details can be obtained from the Medical Secretary, Institute of British Photographers, 38 Bedford Square, W.C.1.

The Universities Federation for Animal Welfare is organizing a Summer School designed for undergraduates of all faculties, to be held at Westham House, Barford, Warwick, during September 14–21. The programme will include visits to a bacon factory, an artificial insemination centre, and the animal house of a medical laboratory, with talks, discussions and films on animal welfare problems in Australia, New Zealand, Nigeria and Germany, the supply of laboratory animals, humane pest control, the training of guide dogs for the blind, humane technique in the laboratory, and slaughtering problems. All inquiries and applications to attend should be sent to Miss M. P. Williams, Universities Federation for Animal Welfare, 7*a* Lamb's Conduit Passage, London, W.C.1.

A UNIVERSITY COURSE IN ARTS AND SCIENCE

THE General Board of the Faculties of the University of Cambridge has prepared a report outlining a course whereby students could undertake study of a science subject as well as of an arts subject. At present no firm recommendations have been made to the University; none will be made by the General Board until the Senate has had the opportunity of discussing the important new questions of educational policy raised by the proposals.

The case for a new university course combining science and arts subjects is persuasively argued in the report. It is well known that a large number of graduates do not make direct use, after they leave their university, of the specialized knowledge they have acquired during their undergraduate days. For many such students it is the nature of the education they receive at the university, rather than the content of their courses, which is important; in the wide range of posts which they may be expected to occupy in national and local government, industry and other fields, the factual knowledge which they have acquired at the university will be of less value than the way in which they have been trained to think. The Board considers that although the majority of such non-specialist students will continue to profit from existing courses either in the arts or in the sciences, there are others who would benefit greatly from an opportunity to study both an arts subject and a science subject at the university.

The new course would give students the advantages of training in both arts and science. Arts men are trained not only to collect accurate data and to use them systematically, but also to exercise critical judgment upon matters of opinion where scholars may reach quite different conclusions. On the other hand, the conclusions of the scientist are based on precise observations and measurements, involve exact calculations, and must be tested by experiment or controlled observation; agreement on essential issues can therefore ultimately be reached. With this distinction in mind, the Board thinks the time is opportune for a new scheme, within the Cambridge Tripos system, designed to give undergraduates an opportunity of undergoing both types of discipline, and of learning to appreciate the advantages and limitations of both. The purpose of the scheme is to provide a course that is specially planned for the undergraduate who knows at the outset of his university career that he does not wish to specialize in science, but who nevertheless wishes to gain a measure of insight into the aims and methods of science.

Although the Board's recommendations are based primarily on the scholarly and intellectual merits of the proposed combination of arts and science subjects, it considers that such a combination would have other, secondary, advantages. Those who took the course as a preparation for an administrative career in which they would most probably have to deal with specialist scientists and to make judgments on scientific matters would be better equipped for their work through having made some study both of the humanities and of scientific method and thought. If Cambridge were to provide the kind of course recommended, it might encourage some schools to establish corresponding combined courses in their sixth forms.

The course recommended by the Board would include one specially designed in science, extending over three terms and the preceding long vacation, which could either precede or follow a two-year course for a part of an existing Tripos in an arts subject. In making this suggestion, the Board emphasizes that it considers it to be the most practicable suggestion at the present time, and not necessarily the ideal course or the only course that might eventually be adopted by the University. It also emphasizes that the proposed course is not intended to train persons who could in any way be regarded as substitutes for qualified scientists. The Board realizes that, at the present time, when the demand for trained scientists is constantly increasing, most of those who have specialized in scientific subjects at school will not wish to take a course combining arts and science. It has based its reasoning on the assumption that the greatest need is likely to be for a course in science specially designed for those who have studied arts subjects at school.

Since the aim of the specially designed course would be to teach science as part of a general education, the emphasis would be on those aspects of science which were of importance to students who did not intend to become practising scientists; the parts of science to be particularly stressed should be concerned with methods of thought which are, so far as possible, different from those used in the humanities.

The course would be planned to study a comparatively narrow branch of science in considerable depth in such a way as to bring out the intellectual content of the subject. The acquisition of some detailed scientific knowledge would be second in importance to learning about the methods of investigation and the methods of thought employed in science. The subject selected for study should be a branch of science which is advancing at the present day and which has wide applications. Researches in it should have been in progress long enough for interesting lessons to be drawn from studying its advances. It should involve some exacting processes of thought, if possible with wider philosophical implications; mathematics should be used little in its presentation.

To begin with, the course recommended is one dealing with radioactivity and the atomic nucleus; a course of lectures lasting one academic year, together with a preliminary course of five and a half weeks in the preceding long vacation, could be so planned as to provide a scholarly study of that branch of physics suitable for undergraduates who had obtained honours in an arts Tripos, and leading up to an examination at honours level. The Board hopes that it may eventually be possible to institute a course illustrating the aims and methods of the biological sciences, possibly on some such topic as 'evolution', which would range over several fundamental sciences.

The Board has considered whether some kind of qualifying examination should be held at any early stage of the science course so as to ensure that the course would only be taken by students who were likely to be able to cope with it; it believes that it would be impracticable to set a formal examination soon enough to fulfil this purpose, but it should be possible for the persons responsible for the teaching for the course to devise tests which would enable them to advise tutors at the end of the proposed preliminary long vacation course whether their students were likely to complete the full course satisfactorily.

Practical classes designed to teach techniques to future specialist scientists would not be appropriate in this kind of course. Instead there would be lecture demonstration experiments designed to exhibit phenomena, and whenever possible the students would be encouraged to manipulate these themselves, and sometimes to take numerical readings for the purpose of demonstrating some quantitative law. A few simple quantitative experiments would be performed by the students, and they would be asked to explain the results. The emphasis would be on the explanation and not on the taking of the observations. The total time spent on practical work would be comparatively small.

The proposed course would be of honours standard; students of good quality should be attracted to the course so that potential employers shall be persuaded that the course is a serious one and not a 'soft option'. To this end the Board proposes that the examination to be held at the end of the proposed one-year course in science should be a Tripos examination; any other name would predestine the experiment to failure.

The Board considers that the teaching for the proposed course should be given by experienced University teaching officers from the appropriate department who are actively engaged in work in their own subject and who wish to take part in this particular experiment; some or all of the normal teaching programme of those who take part in the proposed special course should be taken over by one or more University demonstrators who would be specially appointed for this purpose.

VEGETABLE QUALITY

THE Second International Colloquium on Vegetable Quality was held in the Conservatoire des Arts et Métiers, Paris, during April 24–27. It was organized under the auspices of the Confoederatio Internationalis ad Qualitates Plantarum Edulium Perquirendas, the membership of which comprises those interested in the genetics, biochemistry, physiology, ecology, culture and preparation of edible, and medicinally used, plants. The first colloquium, which had been held in Geisenheim am Rhein in 1955, had not attracted such an international interest as the second colloquium, which had an attendance of about one hundred specialists, including German, Italian, Polish, Russian, British and American workers.

After the visitors had been welcomed by Profs. E. Terroine and J. Dufrénoy (Paris) and Prof. L. Genevois (Bordeaux), Prof. W. Schuphan (Geisenheim) opened the colloquium and outlined the various fields of study of vegetable quality. Quality is the sum of the biochemical properties of the plant and may conveniently be classified under the three headings of external features, suitability, and nutritional factors. Prof. Schuphan stressed the importance of obtaining a correlation between the biological values of nutritionally important compounds and their chemical analyses. The life and work of Prof. A. Scheunert, former director of the Vitamin Institute at Potsdam-Rehbrücke, was commemorated by Prof. Schuphan, while an address on Prof. A. Chevalier, founder of the Colonial Agronomy Laboratory of the Museum of Natural History, was delivered by Prof. M. Portères, the present director of the Laboratory.

Forty-eight papers were presented. As it is not possible to summarize all adequately, an attempt will be made to present an impression of the general trends in the various sessions.

Since vegetable protein is the major protein intake in the unsophisticated diets of the bulk of the world population, it was natural that in the session on proteins and amino-acids the major concern should be with nutritional quality, especially with regard to content of essential amino-acids, of vegetable protein. Prof. Schuphan presented two papers on the analysis of essential amino-acids in the *Brassica* family and the influence of genetical factors on the amino-acid composition; ten different *Brassica* spp. show a wide range of biological activities. Dr. W. Postel (Geisenheim), in a paper on the effect of manuring on the essential amino-acid composition of potatoes, showed that, above an optimal concentration of nitrogen in the soil, there was a decrease in the biological activity of the protein in the potato; it was suggested in discussion that this may have been caused by a lack of carbon for synthesis of these amino-acids. Dr. V. L. Kretovitch (Bach Institute, Moscow) described his work on the biosynthesis of amino-acids in plants, most of which are synthesized by transamination of the appropriate keto-acids. However, tryptophan synthesis is stimulated by the addition of indole, serine and anthranilic acid. Asparagine and glutamine are apparently formed directly in the protein by amination of aspartic and glutamic acids, respectively. Mlle. M. L. Champigny (Gif) discussed the formation of amino-acids during photosynthesis in Crassulaceae. Aspartic- and glutamic acids and alanine, which are derived from Krebs cycle keto-acids, are formed first. However, on long exposures to light the alanine concentration diminishes and that of serine is increased. Mlle. Champigny also described how the amino-acid composition of *Chlorella* proteins varies according to whether urea or potassium nitrate is used as nitrogen source. Using potassium nitrate as compared with urea increases the concentrations of aspartic and glutamic acids but the concentrations of serine and glycine decrease. The microbiological determination of tyrosine, tryptophan, methionine and lysine directly in plant proteins was discussed by Prof. Genevois and Dr. J. Baraud (Bordeaux).

The session on vitamin C was devoted to discussions on the methods of determination of vitamin C and a comparison of the vitamin C content of both European and tropical seed and stone fruits, especially in relation to the satisfaction of nutritional requirements for vitamin C by such foods.

Two complementary papers on the biosynthesis of carotenoids were given by Dr. T. W. Goodwin (Liverpool) and Prof. G. Mackinney (Berkeley, California). Dr. Goodwin discussed mainly the structures and metabolism of compounds which might be precursors of the C_5-repeating unit which is the basis of the C_{40}-skeleton of the carotenoids. The pathway of synthesis of this C_{40}-compound is possibly similar to that of cholesterol in animal tissues; it may involve condensation of eight C_6-acids to give a C_{46}-compound which by six simultaneous decarboxylations gives the C_{40}-skeleton. Prof. Mackinney's researches using leucine labelled with carbon-14 indicate that C_4 of leucine is specifically incorporated into carotene by *Phycomyces blakesleeanus*, suggesting that leucine may form an *iso*-C_5 unit which is incorporated into a carotenoid precursor *in toto*. Extended genetical studies in tomatoes suggest that the Porter–Lincoln series is not operative, but that the aliphatic and alicyclic carotenoids are formed in parallel from the same common precursor. Dr. M. Signol (Paris) reported the effect of tetronic acid on the pigmentation of maize seedlings. Paper chromatography shows an increase in the carotenoid hydrocarbon fraction with a disappearance in xanthophylls, chlorophyll and phæophytin; by column chromatography it was found that the major hydrocarbons were now lycopene and γ-carotene.

During the session devoted to the B vitamins and vitamin E, the oxidation of tocopherols in oils from maize and rice was discussed by Dr. G. Zwingelstein (Lyon); the tocopherols in rice are more stable than those in maize under comparable storage conditions; thus, although initially maize has a higher tocopherol concentration, this rapidly drops to a level below that in rice. Mlle. N. Vokral (Paris), discussing the biogenesis of riboflavin by *Aspergillus niger*, showed that it was dependent upon the magnesium concentration of the culture medium; for example, high magnesium concentrations inhibit flavin synthesis.

Aspects of vegetable quality other than nutritional were discussed in the session on tannins and polyphenols.

In a review of anthocyanins and polyphenols (communicated), Dr. E. C. Bate-Smith (Cambridge) dealt with their relationship to appearance, flavour and texture, and described new types of those compounds which had recently been isolated from plants. Appearance and flavour of such processed vegetable products as tea and cocoa were closely connected with the polyphenol content; desirable cocoa flavour is only obtained in a cocoa bean which has been so fermented that the purple anthocyanin colour has been replaced by a brown colour of phenolic oxidation products. 'Stringiness' in beans has always been associated with lignin deposition, but recent results have indicated also the participation of leucoanthocyanins, which are deposited during cell-wall lignification. Soluble leucoanthocyanins are responsible for hazes, sediments and 'body' of alcoholic beverages. The occurrence and identification of catechins, gallocatechins and their gallates in tea, quinic and shikimic acids in apples and *p*-coumaroyl quinic acid in *Antirrhinum* were the subjects of papers by Academician A. I. Oparin (Bach Institute, Moscow), Dr. A. C. Hulme (Ditton) and Dr. H. Böhme (Berlin), respectively. Prof. J. Masquelier (Bordeaux) described the bactericidal action of certain wines which is associated with the pigmented fraction from which the sugar and the alcohol have been removed. Prof. J. Lavollay (Paris) described experiments on the coupled destruction of ascorbic acid by the action of phenolase on certain ortho-dihydroxy flavonoids. The destructive activity does not depend solely on the presence of ortho-dihydroxy groups since phloretin and naringenin, which do not contain such groupings, are very active. Flavonoids such as quercetin are more active as aglycones, the glycosides quercitrin and rutin being almost inactive.

In the session on mineral nutrition, Dr. D. Bertrand (Paris) gave a comprehensive review of metal enzyme systems; other papers were on the influence of mineral elements on plant growth and the effect of minerals in wheat on flour quality (Dr. W. Morgulis, Toulouse).

The proceedings of the colloquium will be published in Vol. 3 of "Qualitas Plantarum et Materiæ Vegetabiles" (Dr. W. Junk, The Hague), which it is hoped will become the official organ of the Confoederatio Internationalis ad Qualitates Plantarum Edulium Perquirendas.

J. FRIEND

RESEARCH DIVISION OF THE CEMENT AND CONCRETE ASSOCIATION, WEXHAM SPRINGS

THE Cement and Concrete Association is the research and information organization of the Portland cement industry in Britain. Its research and development station is at Wexham Springs, Stoke Poges, Buckinghamshire, where on May 1 the Minister of Works, the Right Hon. Hugh Molson, M.P., opened three new buildings.

These buildings comprise, first, a two-story block containing a printing department, canteen and self-contained hostel with lecture theatre and recreation rooms capable of housing about forty students; secondly, a demonstration hall with an unobstructed floor space, 50 ft. × 100 ft., in which building techniques can be demonstrated in full scale, under cover; and thirdly, chemistry and physics laboratories.

The research station is concerned essentially with the utilization of Portland cement, problems of manufacture being studied elsewhere, and it endeavours to promote the more efficient utilization of cement, as well as finding new applications and acting as a technical service unit for all users of cement. Its activities are carried on by a staff of about twenty graduates and some eighty experimental assistants, tradesmen and labourers in five departments, covering chemistry and physics; concrete (materials and methods of preparation); structural engineering; roads and airfields; works and general services.

The Chemistry and Physics Department concerns itself with chemical and physical problems arising in concrete construction, fundamental research on the nature of hardened cement and maintenance of a standards and instrumentation section which provides facilities for making measurements and the construction of special apparatus. The pure research of the Department is directed to the elucidation of the fundamental structure of hardened cement pastes. For this purpose physical methods of analysis are mainly employed, chiefly X-ray powder photography, measurement of dielectric properties and the study of phase equilibria in the system $CaO—SiO_2—H_2O$.

Applied research has embraced a range of problems some of which, such as the study of the durability of concrete exposed to weathering and chemical attack, are long-term and of indefinite duration. Others have been simple and have required only a few hours work. In this category come measurements of the heat capacity and thermal insulation of concrete walls and floors, and routine analytical tests to determine cement contents of concrete and identify attacking agents. The instrument section provides facilities for the servicing of electrical apparatus and undertakes the design and construction for other departments of instruments which are not available from commercial sources.

The Concrete Department is devoted to the study of the materials for making concrete and to the examination of concrete-making techniques designed to provide specific properties in the final product.

The materials section has the general objective of improving the practice of preparation of aggregates and the design of concrete mixes. To this end it studies methods of testing aggregates and cement, and of assessing the qualities required of concrete as an engineering material. Systematic investigation has enabled the factors which cause variation in quality of concrete to be identified and measured, and has made it possible to design, from widely variable raw materials, mixes which will give concrete having desired properties.

The basic research of the materials section has provided the informed background for the work of the methods section, which examines special uses of concrete and concentrates on improvements in the technique employed. A detailed study has been made of the procedure for laying granolithic floor toppings and a fundamental investigation is being made of frost damage to concrete kerbstones. As part of this work the shrinkage and creep of concrete are being examined with novel apparatus, particular attention being paid to dimensional changes in the setting and hardening period.

The Structural Engineering Department is concerned with the improvement of design methods for concrete structures, improvement of the knowledge of the behaviour of concrete structures, development of new concrete structural forms, and the study of practical constructural problems. The design studies are carried on in close collaboration with other engineering research laboratories and with practising engineers. The Department is fortunate in having available a specially designed laboratory in which tests can be made on full-scale elements of structures or on models of a size which approaches full-scale. Testing is carried out with a large test frame, the base of which is the heavily reinforced floor of the laboratory, and loading is by means of hydraulic jacks. The performance of the structure under test is examined by mechanical and electrical strain gauges and can be recorded automatically.

A special study has been made of the design of shell roofs, of the effect of concentrated loads on bridge decks and of the properties of prestressed concrete structures. The Department has also been able to collaborate with engineers on actual construction, and much valuable information has been obtained relating the performance of laboratory models to that realized in the full-scale structure.

The Roads Department was formed to carry out research and development work on all forms of pavement construction in which cement is used. Its principal interest has been in concrete pavements, lean concrete bases and cement-stabilized soil bases. Experimental work has been carried out on techniques of road laying and of the details of road construction, such as joint making, repair and resurfacing. The Department maintains a close interest in road and airfield work in progress, and its services are extended to site control of unusual and/or particularly important projects. Advisory work is also undertaken for local authorities and others concerned with the building of new roads.

The basic function of the Works and Services Department is the provision of a service of craftsmen and labourers for carrying out all kinds of building operations. All departments call upon the services of this Department for routine maintenance of plant and property and for the carrying out of building experiments which involve the skill of tradesmen. The Department also carries out investigations in its own right and has been particularly interested in the development of attractive surface finishes for concrete. Some hundreds of examples of different surface finishes are undergoing weathering trials on the Station, and architects and others interested in applying them are provided with detailed instructions how to achieve the effects. A further substantial part of the various work of this Department is the organization of field work for training courses. Every year training courses for about forty persons are held at roughly fortnightly intervals, and one of the functions of the Works and Services Department is to arrange full-scale demonstrations of various aspects of concrete technology ranging from simple batching trials to complete demonstration of prestressing techniques.

These training courses are organized by another division of the Cement and Concrete Association, but it was felt most appropriate to hold the courses where the research work is in progress. The success of the courses and the importance attached to communication of the fruits of research are underlined by the decision to provide two of the new buildings mainly for training purposes.

RESEARCH COUNCIL OF ALBERTA

REPORT FOR 1956

THE thirty-seventh annual report of the Research Council of Alberta*, which includes the usual lists of publications of the Council, members of committees, and staff, covers the year 1956, in which the formal opening of the Council's new laboratories and pilot plant on a site adjacent to the University of Alberta was the outstanding feature. The Council's geological effort was further strengthened during the year, and two new advisory committees were established, one dealing with agricultural matters and the other with the problem of hail, commencing with a study of basic cloud physics in co-operation with the Meteorological Division of the Department of Transport.

Encouraging progress was made in coal research, the major effort of the organic chemistry laboratory being concerned with the constitution of humic acids and further studies of the pyrolysis of coal in presence of acid catalysts. Comparison of the infra-red spectra of humic acids, coals and synthetic coal-like substances prepared by oxidative polymerization of hydroquinone at high temperatures suggests that while the concept of a continuous increase of rank in coals is sound, materials giving infra-red spectra typical of bituminous coal may be found in various ways. The Physical Chemistry Laboratory has studied the mechanism of pyrolysis of coal and the solubility of partly carbonized coal. Palæobotanical studies have concentrated on fossil woods and spores, and the collection of modern conifer woods, begun in 1955, is now virtually complete. So also is the first stage of the fluidized coal carbonization programme begun in 1955 in co-operation with the University Department of Chemical Engineering, and it was anticipated that the equipment would be transferred to the Council's new pilot plant in the spring or early summer of 1957. Tests in Germany indicate that it is not possible to manufacture binderless briquettes of commercial quality from Alberta sub-bituminous coal in either extrusion-type or high-pressure ring-roll presses, but the possibility of using hot-briquetting processes is being explored in Europe.

---

* Research Council of Alberta. Thirty-seventh Annual Report, 1956. Pp. 48. (Edmonton: Queen's Printer, 1957.)

Petroleum geochemistry is now recognized as the unifying theme in the work on petroleum, and the programme is being co-ordinated on this principle. Work continued on the porphyrin content of oil and its destruction in relation to the presence of vanadium, nickel and other trace elements. A detailed survey is being made of the occurrence of vanadium and nickel in the Pembina oil field with a view of following oil migration within the field, and the flow of Athabasca oil sand through a hopper is also being studied. Other work has been concerned with the characterization of the sulphur compounds in the oil-sands oil, and the selective oxidation of thiophenic acid sulphur by nitric acid. The hydrocarbon research programme deals with the mechanism of the uncatalysed pyrolysis of hydrocarbons and the decomposition of halo-hydrocarbons.

The work on natural gas has been reoriented, and yields of acetylene and ethylene in the range of commercial interest were obtained by pyrolysis of *n*-butane at about 250° F. and atmospheric pressure, greater severity of cracking favouring the formation of acetylene. Particular emphasis is being placed on the engineering problems associated with the high heat load required for such pyrolytic reactions, and fundamental studies are being made on adsorption with reference to the use of such techniques in separating hydrocarbons.

The geological section is making excellent progress with its ground-water programme, and the surficial geology of the Hardisty–Killam–Kinsella area was mapped on a scale of one inch to one mile. A Cretaceous microfaunal study was completed in co-operation with the University of Alberta and a microfaunal research project on the Exshaw formation initiated. The clay fraction of shale samples collected across the contact of the non-marine Oldham formation and the marine Bearpaw formation is being studied by X-ray diffraction, and chemical analysis and detailed petrographic and stratigraphic studies of the Lower Cretaceous Blairmore formation of southern and central Alberta continued.

Reconnaissance oil surveys were made on 500,000 acres in the Blueberry Mountain sheet, and some 10 million acres were covered in the exploratory soil survey by helicopter from the Lesser Slave Lake to the Saskatchewan boundary. Additional data were accumulated, despite unusually heavy rainfall, in the co-operative irrigation research on solanetzic soils. The highway research programme included fundamental studies on the use of electro-osmosis to inject chemicals into soils of the texture of silts and finer, as well as on the use of chrome–lignin gels for soil stabilization and for the prevention of frost heaving in soils. Comprehensive laboratory tests were made on samples of soils taken from test-holes in areas of extensive slides which have occurred in the vicinity of the town of Peace River.

The industrial engineering services section is primarily a service group, but it undertook some investigations, including work in co-operation with the University Department of Agricultural Engineering, on the utilization of butane in engines. Work in animal science included a study of the influence of the productive energy level of the ration in the reproductive performance and efficiency of turkeys, and a study of the nutritive value of rapeseed oil meal.

HYDRO-ELECTRIC POWER IN THE U.S.S.R.

It is always a matter of interest to the Western world when the veil of secrecy surrounding many of the activities of the inhabitants of the U.S.S.R. is lifted a little. A report was presented to a joint meeting on May 20 of the Institutions of Civil, Electrical and Mechanical Engineers on the visit of six British engineers to the U.S.S.R. to examine the hydro-electric installations there. It is clear that their hosts spared no effort to provide these visitors with the information they desired, especially with regard to those parts of their vast territory which they were unable to visit. It is also refreshingly clear that the visitors were determined to supplement this information with the results of their own observations of the installations and factories seen. In so far as the use of electricity is a pointer to the progress of industrialization of a community, the report is of value in showing the position achieved by the U.S.S.R., and some interesting comparisons with Great Britain are possible. There is a great wealth of factual information given, which makes the report heavy reading, although correspondingly more valuable, and a fair summary of the report must also, therefore, be mainly concerned with facts.

At the present time the electricity generated in the U.S.S.R. per head of population is rather less than half the corresponding figure for Great Britain. This may be accounted for to some extent by the greater proportion of rural to urban population; but another contributory factor is the more extended use of combined steam-power stations, where the heat of combustion of the fuel is partly used to generate electricity and partly used to provide steam for industrial purposes and for space-heating. This dual-purpose type of station is more attractive economically in the U.S.S.R. than in Great Britain on account of the higher proportion of the urban population who live in large blocks of flats, and 30 per cent of the plant capacity of thermal stations is in combined stations.

The rate of growth of electricity consumption in the next five years is estimated at 45 per cent (9 per cent per annum) for Great Britain, and at 88 per cent for the U.S.S.R. If these rates of progress are maintained, the U.S.S.R. should consume more electricity per head than Great Britain by 1967. Of this total electricity generated, the proportion produced by hydro-electric power is 13·5 per cent at present but is estimated to approach 20 per cent by 1960.

The potential hydro-electric power generation of the country is enormous, and has been estimated as approximately eighteen times the total consumption of electricity in the U.S.S.R. to-day. Probably only 50 per cent of this can be developed economically, but even this figure provides a comfortable margin over the country's needs for many years to come.[1] Research work is, however, being undertaken on peaceful uses of atomic energy, and atomic power-stations are planned for areas where there are no local supplies of fuel and presumably no hydro-electric supplies of power.

The development of hydro-electric supplies is always combined with plans to improve the navigability of rivers and to improve irrigation. In most schemes rivers are converted into a series of large lakes and this must entail some loss of potential power through increased evaporation. In one scheme, however, in Armenia, it is proposed to lower the level of Lake Sevan over a period of fifty years in order to reduce the loss due to evaporation. According to the original scheme, the lake was to be reduced to one-sixth of its area, but a less drastic reduction is now under consideration, coupled with the diversion of water from other watersheds to make good the power lost.

The visiting engineers were generally favourably impressed with the quality of the constructional work carried out and with the technical knowledge of the engineers in control, but they mention seeing several instances of the use of rather poor concrete, and the finish of both constructional work and machinery was not always up to the best British practice. One interesting feature was the small use made of timber shuttering, pre-fabricated permanent concrete shuttering being more generally used.

Many of the structures and earthworks are founded on permeable material and a considerable research effort is devoted to the study of soil mechanics and the strength of materials and structures. Extensive use is made of models before starting full-scale construction. Most of the hydro-electric machinery is manufactured in the U.S.S.R., but the party were only able to visit two manufacturing plants. Factory workers work forty-six hours a week including six on Saturday. Overtime is paid at time and a half for the first two hours of each day and then at double time. There are also bonus incentives.

Eighty per cent of the potential water power of the country is east of the Urals, in relatively thinly populated areas, and considerable attention has, therefore, been given to transmission problems. A 400-kV. a.c. overhead line between Kuibishev and Moscow, a distance of 500 miles, has recently been completed, and there is a proposal for an 800 kV. d.c. line between Stalingrad and the Donbas area, a distance of 250 miles. Some indication of policy in the matter of electricity consumption is afforded by the fact that the private consumer may have to pay thirty times as much for his electricity as a favoured industrial consumer.

There is an interesting appendix giving the estimated total production in 1960 showing increases above 1955 ranging from 23 per cent up to a twenty-one-fold increase. Comparable British figures would have been helpful here, especially for the general consumption goods. These figures show, for example, two pairs of footwear per head of population and approximately one refrigerator, one washing machine, and one motor tricycle for every 400 members of the population, as the annual production in 1960.

The members of the visiting party were Sir John Hacking, of Merz and McLellan; Mr. A. A. Fulton, of the North of Scotland Hydro-Electric Board; Dr. S. P. Hutton, of the Department of Scientific and Industrial Research Mechanical Engineering Research Laboratory; Dr. W. MacGregor, of George Wimpey and Co., Ltd.; Mr. R. W. Mountain, of Kennedy and Donkin; and Mr. H. West, of Metropolitan-Vickers Electrical Co., Ltd. A. H. M. Arnold

FRANKLIN INSTITUTE

REPORT FOR 1956

At the annual meeting of the Franklin Institute which was held on January 16, the *president*, Mr. S. Wyman Rolph, gave a brief summary of the activities of the Institute during 1956. The full text of the annual report of the board of managers appears in the March number of the *Journal of the Franklin Institute* (263, 229; 1957).

The report states that the year under review was a successful one, both financially and otherwise, for the Institute. The Laboratories for Research and Development, which celebrated their tenth anniversary in March 1956, became not only self-supporting but even accumulated a surplus, which can be used for the purchase of much-needed additional equipment. For the first time the gross value of the wide range of investigations carried out for industrial sponsors and the United States government exceeded 3 million dollars. The greatest increase in effort occurred in the field of nuclear engineering, and in November a separate Nuclear Engineering Division was established to handle this particular work. The work on air pollution, carried out by the Division of Chemistry and Physics, was expanded considerably, and a mobile laboratory for the analysis of polluted air was used to study the 'smog' problem in the Los Angeles area. A public semi-technical symposium on the subject of air pollution was held at the Institute in October during Philadelphia's 'Cleaner Air Week'. An electronic recorder for the recording of transient events in proper time sequence, which is most useful in the study of mechanical strains and in chemical kinetics, was designed and constructed by the electronics section of the Electrical Engineering Division, and a Remington-Rand 'Univac' digital computer has been installed, which will be used by the analysis section of the Division to solve engineering problems arising from projects in various departments of the Laboratories and also will be available for data processing for other organizations.

The circulation of the Institute's *Journal* increased from 4,734 at the end of 1955 to 4,876 at the end of 1956. The January 1956 issue commemorated the 250th anniversary of the birth of Benjamin Franklin. The group of associate editors of the *Journal* was increased during the year by eight new appointments to widen the coverage in electronics, mathematics, aerodynamics, thermodynamics, solid state physics, biophysics and nuclear engineering. Commencing with the July issue, Dr. J. S. Burlew succeeded Dr. H. B. Allen as editor. This followed Dr. Allen's retirement in January from the positions of executive vice-president and secretary of the Institute, and the appointment of Dr. Burlew as executive vice-president and Mr. H. V. Bail as secretary. In order to make the facilities of the Laboratories better known to industry, the Institute has commenced publication of a series of brochures, of which two, dealing with computation services and industrial colloids and polymers respectively, appeared during 1956. A symposium on "Earth Satellites as Research Vehicles" was held on April 18 as part of a programme to promote the peaceful use of rockets; the full proceedings have since been published as Monograph No. 2.

Details are given in the report of the various meetings and scientific lectures held by the Institute during the year under review; the awards of the Franklin and other medals by the Committee on Science and the Arts; the activities of the Bartol Research Foundation and the Biochemical Research Foundation; the changes in the number of the staff, which increased by twenty to 556; and preliminary figures concerning the finances of the Institute. Separate sections of the report deal with the Museum and public relations. The Museum attendance showed a further increase, continuing the upward trend which commenced in 1951. About 40 per cent of the total of 336,000 visitors were in groups of school children, and for some of them the Museum's Education Division arranged special programmes designed to interest the young people in careers in science and engineering as part of the Institute's effort to help alleviate the shortage of trained people in those professions.

Several events in connexion with the celebration of the Benjamin Franklin anniversary took place at the Institute. A luncheon was held on Franklin's birthday (January 17), at which the City of Philadelphia's special Franklin Medal was presented to Mrs. Eleanor Roosevelt. The Institute has also been responsible for several series of radio and television programmes, including a weekly feature "Science, Servant of Man", which was broadcast from four separate stations. The anniversary celebrations and the broadcasts were all handled through the public relations department of the Institute.

THE WILDFOWL TRUST

READERS of the eighth report of the Wildfowl Trust, Slimbridge, Glos, will quickly detect the quiet pride and confidence which the editors, Peter Scott and Hugh Boyd, and the contributors have managed to convey. The visit of H.M. the Queen in 1956 set a seal on the Trust's first ten years of life and gave it a recognition so well deserved.

The Trust has three main lines of activity and the way in which each of these has expanded is clearly brought out in a report which covers a period of two years. As the results of its earlier work have become known, the Trust's research programme has received increasing outside recognition. Although much of the scientific work is paid for by the Trust itself, the Nature Conservancy has been able to offer increased assistance, while considerable help has been obtained from other, non-governmental, bodies.

In the educational field the value of the Trust's collection has been recognized by a spectacular increase in the number of schools and organized parties visiting Slimbridge. This number rose from 374 in 1953 to 464 in 1954 and 719 in 1955. The recreational value of Slimbridge was reflected in the growth of the number of visitors from 40,000 in 1954 to 90,000 in 1955 and more than 120,000 in 1956.

Although the numbers of wild geese seen at Slimbridge showed no striking increases during 1954–56, the ringing of geese and ducks, there and at other stations, expanded considerably. In 1954 the Trust assumed a large measure of administrative and financial responsibility for duck ringing in Britain. All the eight ringing stations are in the southern half of England and Wales and there is urgent need for ringing to be undertaken farther north and in Scotland and Ireland; this will be done as more money becomes available.

Although the population study of the pink-footed goose continues to be the main Trust investigation, studies were also made of comparatively small-scale ringing of greylags and white-fronted geese. These studies are particularly valuable for the indication they give of the general resemblances between the population dynamics of all three species despite the differences in their breeding places and migration routes and the extent to which they are pursued by man in Britain and other countries. An important parallel to the pinkfoot inquiry is provided by a study of the blue and lesser snow geese of North America by Graham Cooch, of the Canadian Wildlife Service. In his article, Cooch describes his technique for catching these geese during the flightless period of the moult; the method has been based on long-established Eskimo techniques.

Two complementary articles are concerned with wildfowl conservation in North America and in Europe. The first, by F. C. Bellrose and T. G. Scott, deals with conservation in North America since 1945. The second, by Hugh Boyd, shows how American experience has been used on the problems of restocking with hand-reared ducks in Britain; evidence collected by Boyd suggests that it is unlikely that hand-reared ducks can improve shooting on the foreshore.

Besides a wonderful collection of photographs and some black-and-white drawings which could have come only from the pen of the Director, the report contains all the financial information to show that the Trust is now well established; it must be congratulated on selling Christmas cards to the value of £1,341 in one year.

VARIATION IN THE NUMBER OF BUTTERCUP PETALS

FOR five successive years, girls of Westonbirt School have kept a record of the variation shown in the numbers of petals in buttercups. The species investigated was chiefly *Ranunculus acris* with some *R. bulbosus*, and no attempt was made to distinguish between the two in petal variation. The work was done by girls in the second year of a general science course, their average age being 12–13 years. It was carried out when they were first introduced to flower structure and function and could profitably be done by younger or older children. An account of the study has been given by E. A. Potter (*School Nature Study*, 52, No. 207; April 1957).

In the first lesson, each girl had a number of flowers, which she examined, noting and describing in the usual way the number and shape of the various parts. The number of sepals was found to be constant at five, and this result was anticipated for petals. Although the majority of flowers had five petals, there was considerable surprise when some with six, seven and even eight were discovered. Further investigation showed that 'sixes' were very common and that there were 'sevens', 'eights', 'nines', and 'tens' in decreasing numbers. Later many more variants were found, the numbers of petals varying from four to twenty-five. These were tabulated statistically and supported by investigations during the following year. These showed that 'fours' are rare, and that flowers with thirty or more petals were occasionally found. Plants with these 'double' flowers were few in number, and all were growing in a small area within a few inches of each other. Some plants bore only one 'double' and many single flowers; others bore a few flowers, all 'double', though not necessarily with the same number of petals in each, and no single flowers. In counting the petals of 'double' flowers it was often difficult to distinguish them from stamens, the inner petals being abnormal in shape, much narrower, sometimes tubular at the base and almost stamnoid. In all flowers with petals other than five, there was no variation from the normal five sepals.

There is much of value in a simple investigation of this kind. It stimulates the class to take an added interest in the buttercup, it introduces pupils at an early stage of their biology course to the use of statistical method, obviously of a simple type but yet quantitative, where so much of this branch of science is of necessity qualitative. It also encourages pupils not to accept statements such as "the buttercup has five petals", but to question and discover the truth for themselves.

MIDDAY CLOSURE OF STOMATA

Temperature Effects on the Minimum Intercellular Space Carbon Dioxide Concentration "Γ"

LOFTFIELD[1] observed that the stomata of alfalfa, onion and many other plants sometimes closed partially or completely at about midday, reopening later in the afternoon, and Sayre[2] made similar observations for *Rumex patientia*; such closure was not generally accompanied by any obvious correlative changes in the starch contents of the stomatal guard cells in alfalfa or *R. patientia* (onion stomata do not contain starch). Both Sayre and Loftfield attributed midday closure to water-strain, but the large and rapid increases of stomatal starch that normally accompany wilting (for example, Iljin[3]) render this explanation implausible. Nutman[4] obtained evidence that the midday closure of *Coffea arabica* stomata was not due to water-strain and he concluded that high light intensity was the cause; the closure was accompanied by a fall in apparent assimilation rate, but in view of the control of stomatal aperture by the carbon dioxide concentration in the intercellular space system[5-8] a doubt exists as to which was cause and which effect. Heath[9] found that high temperature, above about 25° C., exerted a closing effect upon the stomata of the onion and interpreted this in terms of intercellular space and guard cell carbon dioxide contents. Like Parkin[10], he was under the misapprehension that onion stomata were free of chloroplasts[11-13], but he also directed attention to the unusually high ratio of non-chlorophyllous to green tissue in the onion leaf which might be expected to cause an especially pronounced increase in intercellular space carbon dioxide content with rising temperature. He suggested that the midday closure of onion stomata, and by implication that of *Coffea* stomata also, was a high-temperature effect operating *via* internal carbon dioxide content.

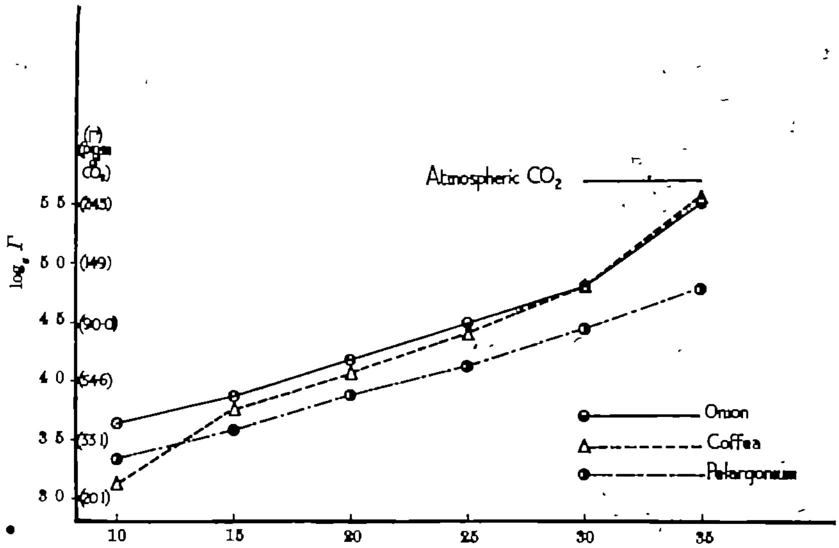

Fig. 1

It was found by Miller and Burr[14] for whole plants and by Gabrielsen[15] and Heath[16-18] using detached leaves that photosynthesis by leaves illuminated with 1,000–2,500 f.c. could only reduce the carbon dioxide content of the air to about 100 p.p.m.; Heath[17,18] interpreted this as the minimum concentration at the surface of the assimilating mesophyll cells. Miller and Burr[14] claimed that this concentration, which will here be denoted by the symbol Γ, was independent of temperature, but Egle and Schenk[19] and the present authors (unpublished) later showed that Γ increased markedly with temperature. The more general aspects of this work will be published later, but a special investigation of temperature effects on Γ for onion, *C. arabica* and *Pelargonium zonale* leaves was made with reference to the problem of midday closure. Heath and co-workers[7,8] had found that wheat stomata (at 25° C.) showed a closing response to increasing carbon dioxide concentration, but only from 100 p.p.m. upwards; a survey experiment on the effects of light intensity and temperature on Γ for a number of species suggested that high temperatures within the physiological range might raise Γ appreciably above 100 p.p.m., thus causing stomatal closure.

The determinations of Γ in air which circulated over the detached leaves in a closed system were made with a Grubb Parsons infra-red gas analyser. The leaf chamber and lead-in tube were immersed in a thermostat bath which was adjusted to maintain the leaf at the desired temperature as indicated by a galvanometer connected to a small thermocouple in contact with the lower leaf surface (or for onion within the leaf cavity). The light intensity was maintained constant at 900 f.c. (tungsten filament) and Γ was determined at 5 deg. C. intervals of leaf temperature from 10° C. to 35° C. inclusive.

The data are shown in Fig. 1 as $\log_e \Gamma$. Owing to shortage of satisfactory *C. arabica* leaves the curve for that species is for one leaf only; the other data represent mean values for three leaves. For *Pelargonium*, which has not been reported as showing midday closure, $\log_e \Gamma$ increased almost linearly with temperature over the whole range, Γ having a relative increase of about 30 per cent for each 5 deg. C. interval and reaching 120 p.p.m. at a leaf temperature of 35° C. For onion and *Coffea*, on the other hand, $\log_e \Gamma$ increased in a similar manner to 30° C., but then rose very steeply, Γ increasing from about 120 p.p.m. at 30° C. to about 250 p.p.m. at 35° C.; the relative increase for onion over this last interval was very significantly ($P < 0{\cdot}001$) greater than the others for either onion or *Pelargonium*, as shown by analysis of variance on log Γ and *t* tests. It should be noted that cut lengths of onion leaf were used in which the leaf cavity, lined with non-green tissue, was open to the circulating air and therefore presumably supplying respiratory carbon dioxide directly to it. Owing to the resistances to diffusion between this air and the substomatal cavities the concentrations in the latter would thus tend to be over-estimated by the measured values of Γ. Subsequent work (Heath and Meidner—unpublished) has shown this effect to be small and has confirmed that the log Γ curve rises very sharply between 30° C. and 35° C., both at 900 f.c. and at 300 f.c., even with the leaf cavity closed at the tip.

An indirect estimate of stomatal diffusive conductance was obtained from the difference between the controlled leaf temperature and the ambient temperature (as a measure of the cooling effect of transpiration) plotted against saturation-deficit; this indicated that the onion stomata closed slightly from 25° C. to 30° C. and markedly between 30° C. and 35° C., whereas those of *Pelargonium* showed no closure and even opened somewhat with rising temperature.

We consider that the closing effect of high temperature on onion stomata, coupled with the rapid increase of Γ between 30° C. and 35° C. shown by onion and *Coffea*, both species known to exhibit midday closure, strongly support the hypothesis that the latter phenomenon is a temperature effect operating through the intercellular space carbon dioxide content. This interpretation is also supported by Heath's[9] observation that the closing effect on onion stomata of a rise of temperature was over-ruled by the opening effect of a concurrent increase of light intensity, for the latter would tend to lower Γ. The light intensity used in the present experiments (900 f.c.) was admittedly considerably lower than midday daylight, but on the other hand, leaf temperatures above 35° C. could well occur under natural conditions—they were not used in this work for fear of after-effects upon the responses to the lower temperatures.

Further support for the hypothesis is given by data obtained by Heath and Meidner[20].

This investigation was carried out while one of us (B. O.) was receiving a maintenance grant from the Agricultural Research Council and forms part of work for which the Ph.D. degree of the University of London was awarded[21].

Effects of Carbon Dioxide and Temperature on Stomata of *Allium cepa* L.

HEATH AND ORCHARD[1] put forward the hypothesis that midday closure of onion stomata might be explained in terms of the observed sudden increase in Γ (the estimated minimum intercellular space carbon dioxide concentration) between 30° C. and 35° C. This hypothesis has been tested in the following experiments.

Experiment 1. This was a 2 × 2 × 2 factorial experiment involving: (*a*) leaf temperatures of 25° C. and 35° C.; (*b*) light intensities of 300 f.c. and 900 f.c. (tungsten filament); (*c*) leaf cavities closed at the tip, as in the natural state, or open and swept with carbon dioxide-free air. The eight treatments were replicated three times (cut lengths of twenty-four leaves) and each was preceded by a standard treatment during which the stomata attained a steady-state opening value. Carbon dioxide-free air was blown against that portion of leaf surface which was used for 'transpiration porometer' measurements. (Details of the transpiration porometer will be published elsewhere.) Steady-state values were maintained for at least 25 min.; the percentage changes from those for the standard treatment were used as data.

At 25° C., at either light intensity, sweeping the leaf cavity with carbon dioxide-free air caused no significant changes in stomatal opening, as compared with unswept leaves with their cavity closed. Apparently at this temperature the accumulation of carbon dioxide in the hollow leaf was insufficient to affect the stomata appreciably, at least under these conditions when carbon dioxide-free air was blown against the leaf externally. (At 25° C. and 900 f.c., $\Gamma = 90$ [1,2] or 70 p.p.m.[2]; at 25° C. and 300 f.c., $\Gamma = 108$ p.p.m.[2].) When the temperature was raised from 25° C. to 35° C., however, at each light intensity the stomata of leaves with the cavity closed underwent a significant closing movement ($P < 0{\cdot}001$ at 900 f.c. and $P < 0{\cdot}01$ at 300 f.c.; at 35° C. and 900 f.c. $\Gamma = 247$ p.p.m.[1,2], at 35° C. and 300 f.c. it would be higher still). This stomatal closure was not observed in leaves with the cavity swept by carbon dioxide-free air, thus supporting the hypothesis of Heath and Orchard, and in fact in such leaves illuminated at 900 f.c. a nearly significant stomatal opening occurred when the temperature was raised from 25° C. to 35° C. (see Experiment 2). This was in accord with the generally held opinion that high temperatures favour stomatal opening[3,4] and suggested that in onion leaves this might be true provided that the internal carbon dioxide concentration could be prevented from reaching too high a value. A further experiment was designed to test more accurately this second temperature effect as well as to provide evidence on the sensitivity of onion stomata to carbon dioxide concentration, which had not yet been directly demonstrated.

Experiment 2. Cut lengths of onion leaves were used in the transpiration porometer and the leaf cavities were swept continuously with moist air; steady-state values of stomatal conductance were maintained for at least 20 min. Four treatments were applied to each leaf, namely: carbon dioxide-free or ordinary air used for sweeping the leaf cavities and blowing on the leaf externally, combined with temperatures of 25° C. and 32° C. The experiment was repeated on four leaves with a light intensity of 300 f.c. throughout.

Carbon dioxide-free air caused wider opening than ordinary air at 25° C. and this difference was even greater at 32° C.; with carbon dioxide-free air the stomata opened farther at 32° C. than at 25° C. These effects were all highly significant ($P < 0{\cdot}001$). There was, however, no evidence of a difference in aperture at the two temperatures when ordinary air was used, suggesting that here the opening effect of the higher temperature was balanced by a closing effect due to its causing an increased carbon dioxide concentration in the guard cells; respiratory carbon dioxide from the chloroplast-free epidermal cells would contribute to this.

It has thus been established: (*a*) that onion stomata respond to increased carbon dioxide concentration by closure, as do those of other species; (*b*) that the high-temperature closure of onion stomata with the leaf cavity closed (as in Nature) can be accounted for by accumulation of carbon dioxide in the leaf; (*c*) that if accumulation of intercellular space carbon dioxide is prevented, high temperature causes opening. This opening effect of high temperature may perhaps not operate through carbon dioxide at all; on the other hand, it may be brought about by the lower solubility of carbon dioxide in the guard cell sap at high temperature.

Information about the effect of temperature on the rate of stomatal opening from darkness has been obtained from a separate experiment at 300 f.c., using carbon dioxide-free air. The rate of opening was significantly greater at 36° C. than at 26° C. ($P < 0{\cdot}001$), the Q_{10} being 2·35 with fiducial limits 2·24–2·46 for P 0·05. This confirms the approximate value of 2 found by Loftfield[5] for alfalfa out of doors and suggests that the rate of a chemical 'dark' reaction is primarily controlling the light opening at 300 f.c. even at such a high temperature range.

This work has been supported by a grant from the Nuffield Foundation; detailed publication will follow in due course.

TRIPHOSPHOPYRIDINE NUCLEOTIDE AS A CATALYST OF PHOTOSYNTHETIC PHOSPHORYLATION

By PROF. DANIEL I. ARNON, DR. F. R. WHATLEY and DR. M. B. ALLEN

Laboratory of Plant Physiology, Department of Soils and Plant Nutrition,
University of California, Berkeley

PHOTOSYNTHETIC phosphorylation[1-10] is a term used to describe the conversion of light energy into the energy-rich pyrophosphate bonds of adenosine triphosphate by isolated chloroplasts, without the aid of other cellular constituents. Isolated chloroplasts are capable of carrying out complete photosynthesis[1,6,11], but when conditions are so arranged that carbon dioxide fixation does not occur, photosynthetic phosphorylation proceeds outside the cell in accord with the overall reaction:

$$\text{Light} + P_i + \text{ADP} \rightarrow \text{ATP} \qquad (1)$$

where P_i represents orthophosphate and ADP and ATP represent adenosine diphosphate and triphosphate respectively.

The catalysts of photosynthetic phosphorylation which were previously identified are magnesium ions, riboflavin phosphate, vitamin K and ascorbate[6-9]. By varying experimental conditions, we have now found two additional catalysts for photosynthetic phosphorylation: triphosphopyridine nucleotide, and a factor present in an aqueous extract of chloroplasts, which appears to function in phosphorylation by reducing triphosphopyridine nucleotide in light. We have also found a method for stabilizing the activity of isolated chloroplasts, thereby enlarging the range of possible investigations of chloroplast reactions *in vitro*.

The effect of triphosphopyridine nucleotide on photosynthetic phosphorylation became apparent at

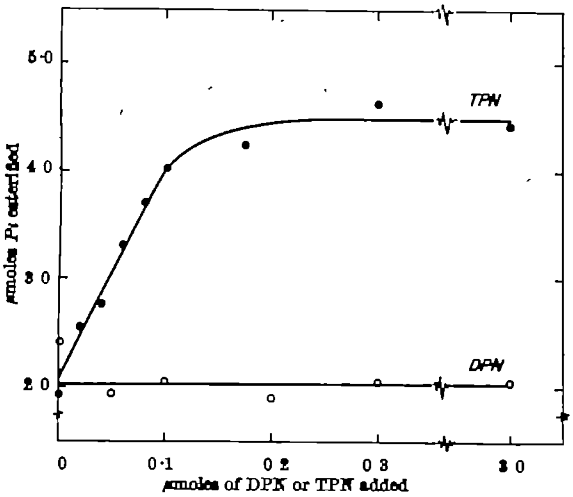

Fig 1. Effect of tri- and di-phosphopyridine nucleotide on photosynthetic phosphorylation.

The reaction mixture contained in a final volume of 3 ml.: 'broken' chloroplasts (ref. 9) containing 0·1 mgm. chlorophyll; *tris*-(hydroxymethyl) amino-methane buffer, *p*H 8·3, 80 µmoles; magnesium chloride, 5 µmoles; sodium ascorbate, 5 µmoles; riboflavin phosphate, 0·01 µmole; vitamin K_3, 0·06 µmole; adenosine diphosphate, 10 µmoles; $K_2H^{32}PO_4$, 10 µmoles; and tri- or di-phosphopyridine nucleotide as indicated. The reaction was run for 20 min. at 20° C. under nitrogen gas. The 'broken' chloroplasts (P_{1s}) correspond to the P_{1w} preparation (ref. 9) except that they were broken by suspending whole chloroplasts in 0·035 *M* sodium chloride instead of water. Measurement of esterified phosphate and all other experimental conditions were as previously described (ref. 8). Illumination as described elsewhere (ref. 11)

a low concentration of riboflavin phosphate and vitamin K, when the concentration of chloroplast material in the reaction mixture was reduced to 0·1 mgm. chlorophyll in 3 ml., the *p*H changed to 8·3 and adenosine diphosphate used as the phosphate acceptor. Under these conditions, the requirement for triphosphopyridine nucleotide was found to be specific and not replaceable by diphosphopyridine nucleotide (Fig. 1). In the earlier experiments[6,9], five times as much chloroplast material was used, the *p*H was 7·4 and adenylic acid served as the phosphate acceptor.

Further modification of experimental procedure yielded evidence for a water-soluble component of the chloroplasts essential to photosynthetic phosphorylation. When chloroplast preparations, such as used in experiments represented by Fig. 1, were washed three times in dilute sodium chloride (0·035 *M*), they lost their capacity for photosynthetic phosphorylation (Table 1). This capacity was restored (Table 1) to the washed green particles upon the addition of an aqueous extract of whole chloroplasts[6,9].

Table 1. EFFECT OF CHLOROPLAST EXTRACT AND OF TRIPHOSPHOPYRIDINE NUCLEOTIDE ON PHOTOSYNTHETIC PHOSPHORYLATION

	Orthophosphate esterified (µmoles)
Complete system, dark	0·4
Complete system, illuminated	6·7
Chloroplast extract omitted	0·7
Triphosphopyridine nucleotide omitted	3·3
Chloroplasts omitted	0·1

Experimental conditions and reaction mixture were the same as described in legend to Fig. 1, except that broken chloroplasts were washed by suspension in 0·035 *M* sodium chloride followed by centrifugation at 20,000 *g* for 5 min. at 0° C. This washing and centrifuging procedure was repeated three times. The complete system also contained 0·3 µmole triphosphopyridine nucleotide and chloroplast extract obtained from a quantity of whole chloroplasts containing 0·5 mgm. chlorophyll

The chloroplast extract has previously been shown to be important in carbon dioxide fixation[6,7,9]. Its role in photosynthetic phosphorylation is at present under investigation, but its effect can be tentatively attributed, at least in part, to a factor required for the reduction of triphosphopyridine nucleotide by illuminated chloroplasts. Its ability to reduce triphosphopyridine nucleotide was established in separate experiments in which the reduction of substrate amounts of triphosphopyridine nucleotide was measured as a function of added chloroplast extract. Phosphorylation was excluded by omitting inorganic phosphate and the requisite co-factors. Reduced triphosphopyridine nucleotide accumulated, in agreement with the recent findings of San Pietro and Lang[12]. Fig. 2 shows that under these conditions the reduction of triphosphopyridine nucleotide was proportional to the amount of the chloroplast extract added. The reduction of triphosphopyridine nucleotide was also reduced, but in our case at a lower rate (compare ref. 12).

The triphosphopyridine nucleotide-reducing factor has some of the properties of a protein: it is non-dialysable, and it is sensitive to heating; heating for 3 min. at 100° C. inactivates it completely. It is stable to acetone and alcohol precipitation. It appears to contain sulphydryl groups, since the reduction of triphosphopyridine nucleotide in our system was severely inhibited by 5×10^{-4} *M* *p*-chloromercuribenzoate. If the triphosphopyridine nucleotide-reducing factor is a protein, then its effect on photosynthetic phosphorylation must be catalytic, since chloroplast preparations which esterified 4·5

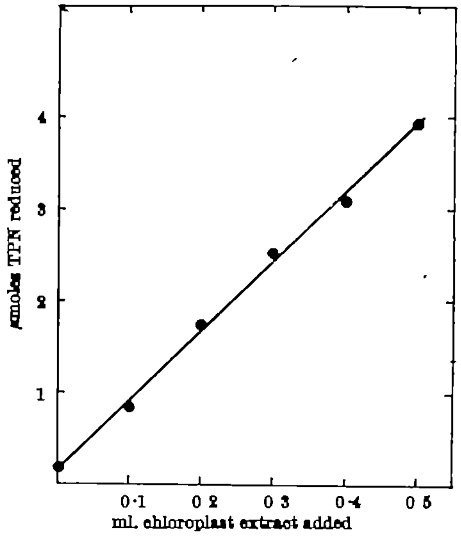

Fig. 2. Light-dependent reduction of triphosphopyridine nucleotide by washed chloroplast particles as a function of added chloroplast extract.

The reaction mixture contained, in a final volume of 3 ml.: 'broken' chloroplasts (P_{1s}), containing 0·1 mgm. chlorophyll, *tris*-(hydroxymethyl) amino-methane buffer, *p*H 8·3, 80 µmoles; sodium chloride, 35 µmoles; triphosphopyridine nucleotide, 6 µmoles; and chloroplast extract as indicated. Chloroplast extract was prepared as described previously (ref. 9), except that 0·035 *M* sodium chloride instead of water was used as the extractant. 1 ml. chloroplast extract was obtained from a quantity of chloroplasts containing 2 mgm. chlorophyll. The reaction was run to completion at 20° C. under nitrogen, with potassium hydroxide in the centre well of the manometer vessel. Illumination as described elsewhere (ref. 11). After centrifuging off the particles, reduced triphosphopyridine nucleotide in the supernatant fluid was measured spectrophotometrically at 340µ

Table 2. EQUIVALENCE OF TRIPHOSPHOPYRIDINE REDUCTION AND OXYGEN EVOLUTION BY ILLUMINATED CHLOROPLAST PARTICLES IN THE PRESENCE OF EXCESS CHLOROPLAST EXTRACT

Triphosphopyridine nucleotide added (μmoles)	Triphosphopyridine nucleotide reduced (μmoles)	Oxygen evolved (μmoles)
0	0·1	0·2
1·0	0·9	1·2
2·0	1·9	2·2
3·0	2·9	3·1
4·0	4·1	4·2

Experimental conditions were as described in legend to Fig. 2, except that chloroplast extract obtained from chloroplasts containing 2 mgm. chlorophyll was added in each case. Triphosphopyridine nucleotide added as indicated. Oxygen evolution was measured manometrically and reduced triphosphopyridine nucleotide was determined as described in legend to Fig. 2

micromoles of inorganic phosphate (Fig. 1) contained only a very small amount of protein (about 0·1 mgm. of total nitrogen in association with 0·1 mgm. of chlorophyll).

As shown in Fig. 2, in a non-phosphorylating system, the reduction of substrate amounts of triphosphopyridine nucleotide (4 μmoles) by catalytic amounts of chlorophyll (0·1 μmole) was made possible by the addition of large amounts of the triphosphopyridine nucleotide-reducing factor. When this factor was present in excess, the reaction went to completion and the accumulation of reduced triphosphopyridine nucleotide was accompanied by a stoichiometric evolution of oxygen (Table 2) in accordance with equation 2:

$$\mathrm{TPN^+ + H_2O \xrightarrow[\text{chloroplasts + extract}]{h\nu} TPNH + H^+ + \tfrac{1}{2}O_2} \qquad (2)$$

Hitherto, light-dependent evolution of oxygen in the presence of triphosphopyridine nucleotide as the hydrogen acceptor has been shown only indirectly by coupling reaction (2) with a suitable dehydrogenase system[13]. Direct evolution of oxygen by reaction (2) was also considered to be difficult on thermodynamic grounds[5,14]. For these reasons the nature of the triphosphopyridine nucleotide-reducing factor and the possible role of its SH-groups are of special interest. It can reduce triphosphopyridine nucleotide only in the light and only with the aid of chloroplasts; it cannot reduce it in the dark, with or without chloroplasts. The triphosphopyridine nucleotide-reducing factor seems to be unnecessary for oxygen evolution by chloroplasts when the reaction does not involve pyridine nucleotides. Oxygen evolution by illuminated, washed chloroplasts with quinone as the hydrogen acceptor[15] (a reaction we found to be independent of added pyridine nucleotides) was unaffected by the omission of the triphosphopyridine nucleotide-reducing factor.

The success of photosynthetic experiments with isolated chloroplasts depends on the stability of the particles after they are removed from the intact cell. With certain chloroplast preparations, a serious loss of activity occurred in unwashed chloroplasts on standing even at low temperatures. In experiments in which chloroplasts were washed, it was important to distinguish between loss of phosphorylating activity resulting from washing and that resulting from the mere delay which the washing procedure entailed. We have now found that the loss of activity on standing can be prevented for a period of several hours if the solutions used for grinding the leaves and washing the isolated chloroplasts contain 0·01 *M* ascorbate. The protective role of ascorbate on isolated chloroplasts may explain, at least in part, its beneficial effect on their photosynthetic phosphorylation and carbon dioxide fixation[1,8,9]. Moreover, seasonal and environmental fluctuations in the ascorbate content of leaves and chloroplasts could conceivably account, at least in part, for the observed variations in the activity and stability of spinach chloroplasts prepared at various times from leaves of different origin.

Since the triphosphopyridine nucleotide-reducing factor of chloroplasts can also reduce diphosphopyridine nucleotide, careful attention to experimental conditions was necessary to demonstrate its specificity for photosynthetic phosphorylation. The specificity of triphosphopyridine nucleotide was observed at concentrations of chloroplast material corresponding to 0·1 mgm. chlorophyll/3 ml. When five times as much chloroplast material was used, or when an excess of chloroplast extract was used, the addition of diphosphopyridine nucleotide was as effective as that of triphosphopyridine nucleotide in increasing photosynthetic phosphorylation. It is conceivable that the non-specificity at the higher concentration of chloroplast material resulted from the presence of bound triphosphopyridine nucleotide and sufficient pyridine nucleotide transhydrogenase[16] to catalyse the reaction:

$$\mathrm{DPNH + TPN \rightleftarrows TPNH + DPN} \qquad (3)$$

The specificity of triphosphopyridine nucleotide for photosynthetic phosphorylation is of special interest if our hypothesis[5–7] is correct that this process, like the more familiar respiratory phosphorylation by mitochondria, represents phosphorylation coupled to an electron transfer chain. In respiratory phosphorylation, so far as is now known[17–19] diphosphopyridine nucleotide, but not triphosphopyridine nucleotide, can serve as the initial electron acceptor. The findings reported here provide the first experimental evidence for the direct participation of triphosphopyridine nucleotide in what is envisaged as a coupled phosphorylation.

The new evidence allows us to include triphosphopyridine nucleotide as a hydrogen or electron carrier not only in carbon dioxide fixation, as was reported earlier[8–9], but also in photosynthetic phosphorylation by isolated chloroplasts. This conclusion is in accord with the identification of a reduced triphosphopyridine nucleotide diaphorase in leaf extracts by Whatley[20] and the recent isolation of this enzyme from chloroplasts by Avron and Jagendorf[21]. They have found[21] this enzyme capable of oxidizing reduced triphosphopyridine nucleotide and of transferring electrons from reduced triphosphopyridine nucleotide to riboflavin phosphate and menadione, two known catalysts[5–7] of photosynthetic phosphorylation.

If triphosphopyridine nucleotide has the same role of initial electron acceptor in photosynthetic phosphorylation as that which diphosphopyridine nucleotide has in respiratory phosphorylation, then the two processes appear to differ in both their initial and terminal electron acceptors. The terminal electron acceptor in respiratory phosphorylation by mitochondria is molecular oxygen. The terminal electron acceptor in photosynthetic phosphorylation by chloroplasts is not molecular oxygen but some as yet unidentified oxidized product of the light reaction. Chloroplasts will not carry on phosphorylation in the dark with reduced triphosphopyridine nucleotide and molecular oxygen. These differences support the view expressed earlier[5–8,10] that photosynthetic and respiratory generation of adenosine triphosphate, occurring at two different sites in the green cell, are catalysed by two different enzyme systems. This conclusion does not rule out the possibility that certain individual enzymes and reactions in photosynthetic phosphorylation are similar to those in respiratory phosphorylation.

The high rates of photosynthetic phosphorylation which were attained in some recent experiments may be of interest. The most active chloroplast preparations esterified 400 μmoles of phosphate per hr. per mgm. chlorophyll (or per mgm. nitrogen). These rates are more than a hundred times greater than those first reported[1] and are comparable with maximum rates of conversion of light into chemical energy during photosynthesis by whole leaves in saturating light and carbon dioxide supply[22], namely, 200 μmoles oxygen per hr. per mgm. chlorophyll.

After this work was completed, there appeared the report by Avron and Jagendorf[23] of an extractable chloroplast factor essential for photosynthetic phosphorylation. Their factor was prepared by a procedure similar to that which we have used in extracting the triphosphopyridine nucleotide-reducing factor, but the authors seem to have tentatively ruled out the reduction of pyridine nucleotides as a function of the extract. Another difference between our results and those of Avron and Jagendorf is the inability of their washed chloroplasts to use adenosine diphosphate as a phosphate acceptor. Our washed chloroplasts used adenosine diphosphate in preference to adenosine monophosphate, resembling in this respect the particles from photosynthetic bacteria investigated by Frenkel[24].

SEROLOGICAL CHANGES CONCOMITANT WITH THE GROWTH OF MOUSE TUMOURS IN PRETREATED RATS

By M. PIKOVSKI, C. TAL, M. SCHLESINGER and E. MARGOLIASH

Departments of Experimental Pathology (Cancer Research Laboratories) and Laboratory of Experimental Neurology, Hebrew University—Hadassah Medical School, Jerusalem

A TRANSPLANTABLE mouse mammary carcinoma (*MMC*) of the *RIII* strain, grafted subcutaneously, was shown to grow progressively in rats, pretreated with some lyophilized mouse tissues of the donor strain, or of genetically unrelated strains[1]. In untreated rats there was no growth. It was later shown that a sarcoma which was induced and transplanted in mice of the *C57* Black strain (SBL_1) could grow in rats pretreated with lyophilized preparations, either of the sarcoma SBL_1 or of the genetically unrelated carcinoma *MMC*.

In the present work, rats one week old were injected intraperitoneally with a suspension containing 20 mgm. of lyophilized *MMC*, twice weekly for a period of five weeks, and one week later grafted with minced fresh carcinoma *MMC* or sarcoma SBL_1. Sera of these rats were titrated for their ability to agglutinate single-cell suspensions of mouse tumours and of mouse red-blood cells in saline. The single-cell suspensions were obtained by passing solid tumours with the addition of saline several times through a stainless steel gauze (80 mesh, Endecotts, Ltd., London), using the upper part of the suspension after it was left to settle for 30 min. at 4° C. The results were read after a gentle shaking of the test-tube. The intensity of the agglutination expressed itself both by the titre and the size of the clot produced. These varied from a single large pellet to many smaller clots which could not be broken up by shaking. In sera not containing agglutinins the cells settled, but formed a cloudy suspension on gentle shaking.

The results of a study of the sera of rats pretreated and grafted with carcinoma *MMC* (Fig. 1) show that agglutinins against these tumour cells and red blood cells of mice of the *RIII* strain reached titres of 1 : 80 to 1 : 320 and 1 : 80 to 1 : 160, respectively, at the end of the pretreatment. Normal untreated control rats of the same sub-line of our inbred strain showed practically no tumour-cell agglutinins, and 50 per cent of them showed low titres of red-blood cell agglutinins. During the growth of carcinoma *MMC*,

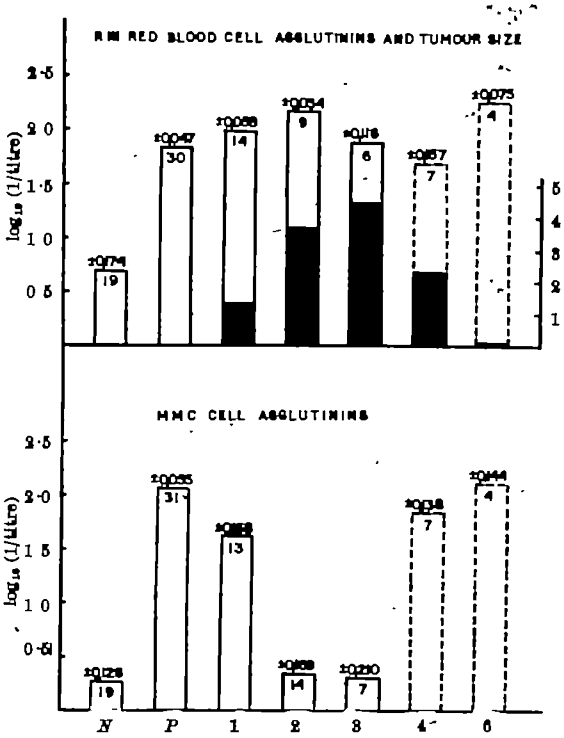

Fig. 1. Changes in titre of agglutinins against carcinoma *MMC* cells and red-blood cells of the *RIII* strain of mice, in sera of rats after pretreatment with lyophilized carcinoma *MMC* and during growth and/or regression of the latter.

The dark part of the columns representing the hæmagglutinin titre is the mean tumour size (mean of two diameters in cm.). *N*: sera of normal untreated adult rats. *P*: sera taken at end of pretreatment with lyophilized carcinoma *MMC*. 1, 2 and 3: sera taken one, two and three weeks, respectively, after grafting, during progressive growth of carcinoma *MMC* (solid lines). 4 and 6: sera taken four and six weeks after grafting, during regression of carcinoma *MMC* (broken lines).

The height of the columns represents the mean of the logarithm of the reciprocal of the titres

$$\left(\frac{\Sigma \log_{10} \frac{1}{\text{titre}}}{n}\right)$$

The numbers above each column are the logarithms of the standard error of the mean

$$\therefore \quad \text{S.E.} = \pm \sqrt{\frac{\Sigma d^2}{n(n-1)}}$$

The numbers in each column are the number of animals tested in each group (*n*).

the tumour-cell agglutinins fell to zero in most of the animals within two to three weeks after grafting, when the tumours reached large sizes, and did not rise again when the tumours continued to grow progressively, until the death of the rats. However, in those rats in which the tumour regressed, the tumour-cell agglutinins reappeared in the serum when regression began and reached titres similar to those of the pretreated animals when regression was complete. Such rats were immune to carcinoma *MMC*, in the sense that a second graft failed to grow.

The red-blood cell agglutinins behaved differently; their titre was not affected by either the progressive growth or the regression of the tumour. Thus, there was a clear dissociation of hæmagglutinins and tumour-cell agglutinins in rats bearing heterologous tumours, though both antibodies were at a high level in pretreated or in immune animals.

The disappearance of the carcinoma *MMC* cell agglutinins during the growth of this tumour in pretreated rats could be attributed to: (1) non-specific reduction of the antibody-level by tumour growth[1]; this was unlikely since hæmagglutinins were unaffected and it could be shown that other mouse and rat tumours growing in rats pretreated with lyophilized carcinoma *MMC* did not cause a decrease of *MMC* cell agglutinins; (2) presence of blocking antibodies in sera of tumour-bearing rats[2]; this was also unlikely, since no such antibodies could be demonstrated by the addition of sera of tumour-bearing rats to sera of immune and of pretreated rats; (3) specific absorption of these antibodies by the tumour; this explanation appeared to be the most probable, since *in vitro* absorption of sera of pretreated rats showed that suspensions of carcinoma *MMC* cells completely removed the *MMC* cell-agglutinin titres with almost no change in *RIII* hæmagglutinin titres, whereas *RIII* red-blood cells completely absorbed hæmagglutinins, leaving the tumour agglutinin titre unchanged.

The behaviour of the hæmagglutinins described above was similar to that observed by Gorer[3] and by Mitchison and Dube[4] concomitant with the pretreatment of mice, and the growth and regression of tumour homografts in such mice. The possibility of a causal connexion between the presence of isohæmagglutinins and the enhancement of growth of mouse-tumour homografts was discussed by Kaliss *et al.*[5] and by Billingham *et al.*[6].

In the present study the behaviour of the titres of the tumour-cell agglutinins differed from those of the hæmagglutinins, and had a concomitant relation to the growth of the heterotransplant. It could, however, be shown that neither the presence of hæmagglutinins, nor the presence of specific tumour-cell agglutinins and their absorption by the growing tumour was essential for the growth of the heterotransplant. Indeed, though the pretreatment of rats with lyophilized carcinoma *MMC* was not followed by the appearance of agglutinins against cells of the sarcoma SBL_1 or against red-blood cells of *C57BL* mice, sarcoma SBL_1 grew as readily as the carcinoma *MMC* in such animals. Sarcoma SBL_1 growing progressively in these rats did not cause any significant decrease in the titres of agglutinins against carcinoma *MMC* tumour cells and the *RIII* red-blood cells.

Thus, although in the present heterologous tumour-host combinations, it was possible to demonstrate in sera of rats pretreated and grafted with the same mouse-tumour strain the presence of specific tumour agglutinins and compare their behaviour with that of the hæmagglutinins, none of the serological changes reported above appear to be essential for the growth of a heterograft. It should, however, be noted that the agglutinations were carried out in saline, without the addition of dextran, so that the conclusions apply only to 'complete' antibodies.

We are indebted to Dr. M. Feldman, of the Weizmann Institute of Science, for supplying us with sarcoma SBL_1, which he established. The skilled assistance of Miss Y. Levi is greatly appreciated. Grants by the Helen Ecker Cancer Society and by the Cancer Trustees, London, are gratefully acknowledged.

Observation of Short-lived Free Radicals in Solution

THE direct detection of short-lived free radicals by physical methods such as spectroscopy and mass spectrometry has become a valuable means of identification and kinetic study in the gas phase. It has not hitherto been possible to study these radicals in a comparable manner in solution, although radicals which exist in detectable equilibrium concentrations, such as triphenyl methyl, are, of course, readily observed spectroscopically. During our study of triplet states in solution, it was necessary to use purified solvents of high viscosity which had been thoroughly freed from dissolved gases, and we have found that these solvents are suitable for the detection and study of a number of reactive free radicals. The function of such solvents is to retard the diffusion-controlled recombination without offering alternative rapid reactions with the solvent itself.

The solvent which has been found most useful is high viscosity (between 25 and 300 centipoise) paraffin, carefully freed from aromatics and other impurities by separation on a silica column and then thoroughly degassed by successive freezing and evacuation. No free radicals were detectable unless the solvent had been carefully freed from dissolved oxygen. A number of absorption spectra attributed to free radicals has been observed by the flash photolysis of solutions in this solvent. Two examples will be given for which the identification of the spectra is fairly certain and which represent two important classes of aromatic radicals.

(1) *Benzyl and diphenyl methyl.* Flash photolysis of 10^{-3} molar solutions of benzyl chloride in viscous paraffin resulted in the appearance of a transient absorption (Fig. 1) with a maximum at 3175 A., a second maximum at 3060 A. and a decay time of about 2 msec. It was later possible to detect this spectrum in hexane solution at the shortest delay times, but the decay in this solvent was too rapid for kinetic study. An identical spectrum was obtained from benzyl formate and the same bands, with additional absorption due to other species, appeared after photolysis of benzyl alcohol and benzyl methyl ether. The assignment of the spectrum to free benzyl is fairly certain when it is compared with absorption spectra of the radical in the vapour phase[1] and in rigid glasses[2], the assignment in the latter case having recently been unequivocably established[3]. The wavelength shifts in solution and in rigid media are typical and well known in other molecules. Photolysis of diphenyl methane gave a similar spectrum with an absorption maximum at 3350 A., and a weaker maximum at 3140 A. which is assigned to the diphenyl methyl radical by comparison with results obtained in rigid media[2,3]. It is worthy of note that, in the vapour phase, the photolysis of diphenyl methane leads to fission of a carbon–carbon bond and production of benzyl. It seems that, although fission of this bond may be favoured energetically, the separation of a hydrogen atom occurs more readily than that of a more bulky phenyl radical in the condensed phases. The absorption maxima in the three phases are:

Molecule	Radical	λ (A.) (solution)	ν cm.$^{-1}$ (solution)	ν cm.$^{-1}$ (gas)	ν cm.$^{-1}$ (glass)
Benzyl chloride Benzyl alcohol Benzyl formate Benzyl methyl ether	Benzyl	3175	31,500	32,760	31,380
Diphenyl methane	Diphenyl methyl	3345	29,900	(benzyl)	29,840

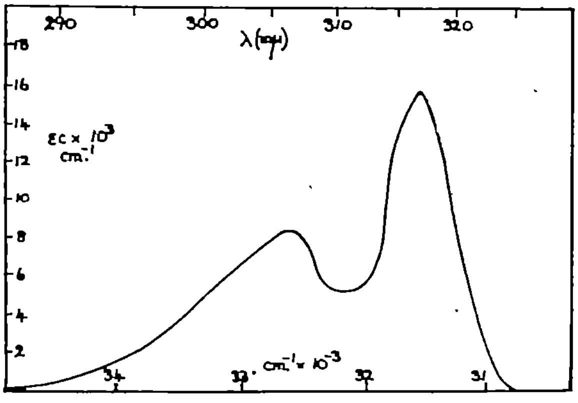

Fig. 1. Absorption spectrum of free benzyl in paraffin solution

Since reaction of these radicals with hexane and with higher paraffins should not differ greatly, the much lower rate of disappearance in viscous paraffin indicates a diffusion-controlled reaction of which the most probable would be bimolecular collision to form dibenzyl. This interpretation of the reaction is confirmed by our finding that the decay of benzyl is second order. The rate constant in paraffin (η = 163 centipoise) was $7 \cdot 8 \times 10^4 \times \epsilon$ litre mole^{-1} sec.$^{-1}$, where ϵ is the extinction coefficient at the 3175 A. maximum.

The benzyl and diphenyl methyl radicals are chemically intermediate between the stable triphenyl methyl and the very reactive methyl radical. Although they dimerize very rapidly, their resonance stabilization results in a relatively high energy of activation for hydrogen abstraction from the solvent, which is probably greater than 15 kcal./mole for benzyl and diphenyl methyl, and it is this which makes their detection possible. The methyl radical, the spectrum of which has recently been detected by flash photolysis in the vapour phase[4], has an activation energy for hydrogen abstraction from paraffins of about 8 kcal./mole, and its life-time in paraffin solution would therefore probably be too short for detection by present techniques.

(2) *Benzosemiquinone.* The flash photolysis of solutions of benzoquinone is followed by a complex series of changes which will be described more fully in a later publication. In viscous paraffin solution the spectrum, immediately after photolysis, consists of two absorption regions, the first with a maximum at 3940 A. and the second with a sharp maximum at 3420 A. and a weaker band at 3310 A. Both absorptions decay with a half-life of a few hundred microseconds, and are shown in Fig. 2.

The maximum at 3940 A. is to be compared with the spectrum obtained in rigid solvents after photolysis both of benzoquinone and hydroquinone[2,5] and attributed to the neutral semiquinone radical. It is to be distinguished from the semiquinone radical-ion, which is relatively stable and can be detected in equilibrium concentration in some quinones though it has not yet been detected in this manner in benzoquinone itself. The neutral radical must be formed

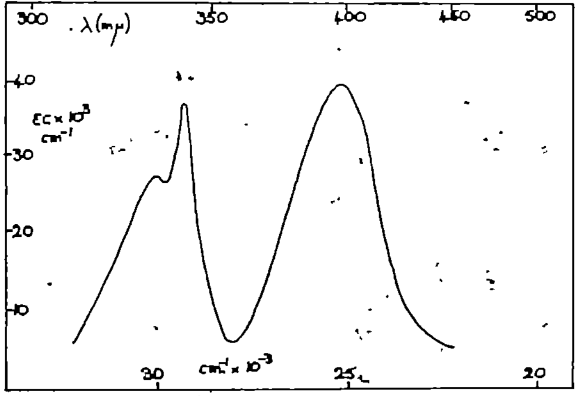

Fig. 2. Absorption spectrum attributed to benzosemiquinone

via the excited quinone molecule by hydrogen abstraction from the solvent, and be stable enough to survive further hydrogen abstraction from the solvent over the period during which it is observed. Its long life in viscous paraffin again indicates a diffusion-controlled bimolecular reaction of removal.

Detailed kinetic studies of these and related radicals in solution are in progress and will be reported later.

We are grateful to the British Rayon Research Association and to the Royal Commission for the Exhibition of 1851 for research fellowships to one of us (M. W. W.) during the tenure of which this work was carried out.

Point of Attack in Hydrocarbon Oxidation

A conflict apparently exists between the aldehyde degradation mechanism indicated by the recent findings of Bailey and Norrish[1] and of Knox and Norrish[2], on one hand, and the preferential attack at the tertiary and secondary carbon atoms deduced, indirectly, by Walsh[3], Boord[4] and Badin and Pease[5]. A possible solution is provided by some recent studies, by gas-phase chromatography, of the products of slow oxidation of *n*-heptane, in a flow system. Although no tests for formaldehyde were made, aldehydes from C_2 to C_6 were detected at 300° C.; at 280° C., however, the extent of reaction was very small, and the only products condensed at − 80° C., apart from traces of peroxides, consisted of propionaldehyde and *n*-butyraldehyde. This suggests that the initial attack is at one of the secondary carbon atoms, with subsequent fission of one of the central C—C bonds. The more reactive chain carriers formed during this process can then attack the primary carbon also, and lead to the formation of higher aldehydes.

This deduction is supported by preliminary results obtained during studies of the partial, slow reaction of mono-deuterated propanes with a small proportion of oxygen. By carrying out kinetic studies, *in situ*, on an infra-red spectrometer (Burt and Minkoff[6]), conditions were selected which avoided fission of the C—C—C skeleton. The deuterium content of the liquid products was then determined, using an infra-red method. From experiments with $CH_2D.CH_2.CH_3$ and $CH_3.CHD.CH_3$, and making some assumptions which are discussed below, it was deduced that at 360° and at 420° C., attack on the secondary C—H or C—D bond was at least 1·9 times faster than that on the corresponding primary bond.

Two of the assumptions are not likely to affect the conclusions appreciably. The first is that the relative amounts of OH and OD bonds formed are proportional to the rates of attack at each CH and CD bond in the original molecule, and the second involves the supposition that there is little, if any, difference in the isotope effect on the rate at the different positions. The third possible source of error requires more detailed consideration: at first sight, it might be expected that the formation of propylene from a propyl radical must involve the loss of hydrogen from a carbon adjacent to that at which attack initially occurred. Thus, if both steps involve oxygen, the deuterium content of the water should not permit an experimental distinction. However, it can be shown that if this were true the D : H ratios would differ considerably from those which were observed. It must therefore be deduced that the formation of propylene from the propyl radical, under the present conditions of large excess of hydrocarbon, involves reactions with radicals or molecules which contain no oxygen. Further experiments are in progress to confirm and extend these results.

Micelles of Long Life: a Step towards Biological Organization

Investigations into the state of solution of paraffin-chain salts have usually ignored the question of the life-time of the individual aggregates (micelles)[1]. Their size is known to be limited, and they are in strict equilibrium with the free long-chain ions in solution[2]. It would appear to follow that their number fluctuates about a mean, and that the life-time of any one micelle, while small, is not capable of exact definition, especially if there is a range of sizes up to the maximum.

It is known that the size limitation may apply to one or two dimensions only; the presence of very large aggregates is shown by the high viscosities of

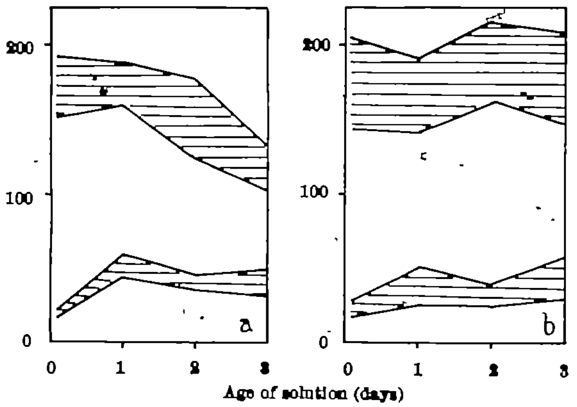

Fig. 1. Apparent specific viscosity at 20° of two states of a polymicelle solution. upper region, high-viscosity solution; lower region, low-viscosity solution. Rate of shear, about 1 sec.$^{-1}$. (*a*) Cetyl trimethyl ammonium bromide/1-naphthol/salt. (*b*) Cetyl trimethyl ammonium bromide/2-naphthol/salt

dilute solutions of some paraffin-chain salts[3]. There is general agreement that such behaviour is due to linear micelles; Halsey[4] has given theoretical reasons for their stability. Evidence is now available that some of these 'polymicelles' can be so long-lived as to have virtually a permanent individual existence.

In experiments with dilute solutions of cetyl trimethyl ammonium bromide and either of the naphthols, it had repeatedly been noticed that the viscoelasticity depended not only on the composition but also on the way the solution was made up[5]. Particularly striking were the differences observed in the rates of foam drainage[6]. To confirm this effect by more conventional methods, measurements were made in a Couette-type viscometer, such as was used by earlier workers[3]. Two systems were investigated, cetyl trimethyl ammonium bromide/1-naphthol/sodium bromide and cetyl trimethyl ammonium bromide/2-naphthol/sodium bromide, 0·5, 0·5 and 1·0 m*M* in water, respectively. A low-viscosity solution resulted when the order of addition was *M*/20 alcoholic naphthol, *M*/20 aqueous salt and *M*/20 aqueous cetyl trimethyl ammonium bromide; a high viscosity one when the order was cetyl trimethyl ammonium bromide, naphthol, salt. The results are shown in Fig. 1, samples being taken on successive days to show the stability of the individual states. Because of the characteristic fluctuations in the reading, a range is shown, covering the last 30 min. of a 60-min. run, or 180 revolutions of the cup, every day.

No analysis is needed to see that each solution exists in two different states. If molecular aggregates were continually forming and disappearing, there could be only one state; it follows that these polymicelles are permanent structures, low-viscosity solutions having more but smaller ones than high-viscosity solutions. Momentary heating to 40° destroys all trace of viscoelasticity, but the two states reappear on cooling. Momentary heating to 50° converts a low-viscosity solution to a high-viscosity solution, the latter remaining unchanged. Loss of individuality with such mild treatment indicates that the polymicelle is only just complex enough to exhibit the new property. Its structure has been discussed elsewhere[5]; an essential factor is thought to be π-electron interaction between neighbouring parallel aromatic molecules[7] adsorbed on to the outside of the cationic micelle. The compatibility of a permanent structure with the free diffusion of its components is of theoretical importance, and it is hoped that a study of these relatively simple systems will help in the understanding of the formation and activity of physically unstable biological aggregates such as β-lipoprotein.

Photochemistry of Polymer Films

Ford[1] has reported that when nylon polymer films are irradiated in the presence of oxygen, a new absorption band develops around 2900 A., which increases in intensity on storage in the dark and is reduced on re-irradiation to about the pre-storage value. His explanation of this phenomenon with nylon films was that oxygen was directly responsible for this effect. We have recently been investigating this stepwise 'post-irradiation effect' and have found that it occurs with several other polymer films, is no less prominent in nitrogen than in oxygen, and is not restricted to a particular absorption band. It therefore seems doubtful whether these changes in absorption spectra are the result of the reaction of the polymer with oxygen.

The chemical changes produced in polymer films on irradiation are undoubtedly complex. In some of our experiments we have exposed transparent films of cellulose (deplasticized, British Cellophane, Ltd., *PT*300, 0·00085 in. thick) and cellulose acetate (deplasticized, British Celanese, Ltd., 0·001 in. thick) to the radiations from a low-pressure mercury-vapour lamp emitting mainly at 2537 A. During these experiments streams of dry oxygen or dry nitrogen (oxygen-free) were passed through the quartz cells in which the films were contained and in which absorption measurements were made. As is clear from Fig. 1, the optical density of the two films increases much more in nitrogen than in oxygen, and it has been found that this difference between the results in the two gases increases with longer times of exposure. However, we have also found that films of nylon (polyhexamethylene adipamide) and its N-methoxylmethyl derivative behave differently, and here the optical density of the film is somewhat greater after irradiation in oxygen than in nitrogen, although the effect of irradiation in the latter gas is by no means insignificant.

The changes in other properties of the polymer films do not seem to be closely connected with the results of absorption measurements. Thus, the nylon-type polymer films showed the greatest increase in optical density for a given exposure, whereas the changes in the plastic properties of the films seemed relatively quite small. The cellulose-type films showed smaller changes in absorption on irradiation but more rapid deterioration of film-like properties. In the latter respect, the changes were significantly greater

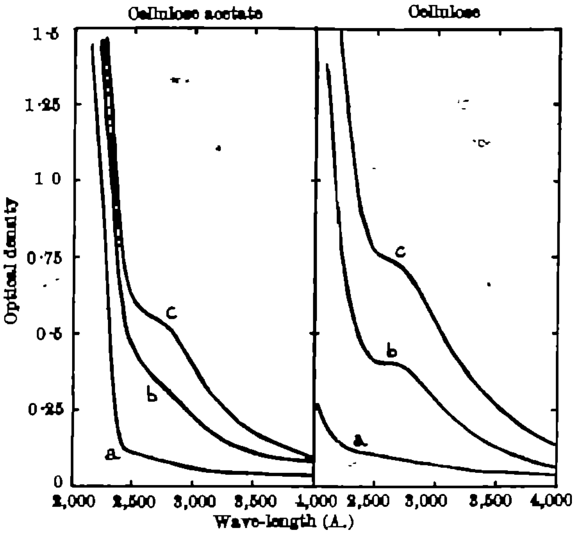

Fig. 1. Films of cellulose and cellulose acetate exposed to low-pressure mercury-vapour lamp at 35° C.: (a) unexposed; (b) exposed 200 hr. in dry oxygen; (c) exposed 200 hr. in dry nitrogen

in oxygen than in nitrogen. After irradiation for 270 hr. in dry oxygen, the cellulose acetate film collapsed to a fine powder, whereas even after 500 hr. the film exposed in dry nitrogen still retained the character of a film although it was very brittle on removal from the quartz cell. Likewise, the cellulose film was slightly less brittle after irradiation in nitrogen than in oxygen.

On storage in the dark after irradiation, the optical density of all these films increases, possibly as the result of the slow combination of free radicals trapped in the polymer. The resultant products are presumably broken down again on re-irradiation. These changes are produced in either oxygen or nitrogen, and would seem to be largely independent of the atmospheric conditions. Typical results are shown in Fig. 2 for cellulose acetate film which was irradiated in dry nitrogen and dry oxygen, stored in the dark in the same gas, and afterwards re-exposed. The results are recorded at one particular wave-length (2600 A.), but at wave-lengths near this the results were qualitatively the same. The change on storage in the dark is relatively slow; thus the optical density, which after 50 hr. irradiation was 0·316 in nitrogen, rose to 0·389 after 24 hr. and to 0·441 after 250 hr. On irradiation after storage in the dark for the latter period, the optical density fell rapidly, and in 2 min. had dropped to 0·410 and after 10 min. irradiation to 0·388. Thus the change on re-irradiation seems to be very much faster than that occurring on storage in the dark.

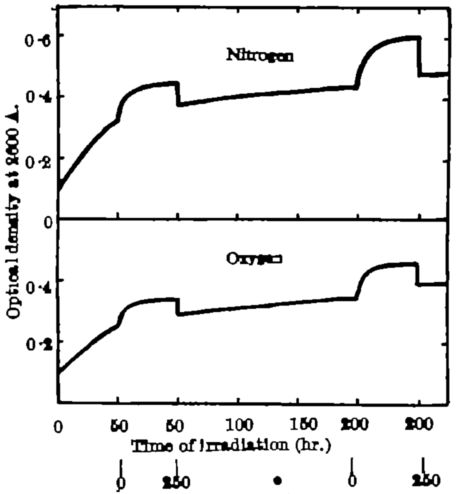

Fig. 2. Effect of storage and re-exposure on optical density of irradiated cellulose acetate film (all treatments at 35° C.)

The results in nitrogen for other times of prior irradiation, for exposures in oxygen, and for other polymer films seem to follow the same pattern. This common behaviour with respect to changes in optical density and its independence of the atmosphere would seem to indicate that there is little connexion between this optical phenomenon and the actual change in other physical properties of the polymer film. Moreover, in confirmation of the greater deterioration of the plastic properties of cellulose acetate film in oxygen, it is known[2] that the tendering of cellulose acetate rayon yarn is much greater when irradiated with a low-pressure mercury lamp in oxygen than in nitrogen.

It would not seem unreasonable to suppose that on irradiation these polymer films give rise to free radicals, which only slowly recombine because of the limitations of movement in the polymer mass. On storage in the dark some recombination with themselves or the polymer occurs, but the compounds so produced are very susceptible to photolysis, and on further irradiation the process is reversed and the free radicals reformed.

A Moving-Paper Collector for Column Chromatography

Dewar and Gunew[1] have described the use of a serrated glass strip as a collector for column chromatography. In this laboratory a method has been developed in which a moving strip of paper is used for the same purpose.

The advantages of this method are its simplicity, its sensitivity to drop-by-drop changes of composition and concentration in the eluate, and its presentation of the eluted compounds in series on paper where they may be identified or estimated with the normal reagents of paper chromatography.

The apparatus (Fig. 1) consists of a kymograph motor and drum, two rubber-covered rollers on which the drum rests, and a further pair of rollers which serve to maintain a slight tension on the filter paper strip.

A strip two inches wide is drawn by the revolving drum from a freely suspended roll of paper, through the paired rollers and under the dripping point of the

Fig. 1

chromatographic column at the minimum speed consistent with the collection of separate drops.

The spots, which dry as they are carried along, are then treated with suitable reagents. The development of ninhydrin colours with amino-acids can, for example, be achieved by passing the dried paper through a solution of that reagent in acetone and a heated 'tunnel' as illustrated in Fig. 1. For quantitative determinations a photoelectric scanner may also be placed in series.

When a limited number of drops are to be collected, a continuous strip of filter paper passing around two drums is adequate for the purpose. A wider paper is recommended for this method, as it is then possible to move the dripping point at the end of each completed circuit, and continue the collection of drops in parallel lines without changing the paper each time.

Variation of the Horizontal Force near the Magnetic Equator

Since November 1955 a magnetic observatory has been in operation at University College, Ibadan (lat. 7° 26′ N., long. 3° 54′ E.), 2° 34′ south of the magnetic equator. Between November 25, 1956, and January 22, 1957, photographic recordings of the variation of the horizontal component H of the Earth's magnetic field were made for a period of a week at each of nine field stations between lat. 6° 36′ N. and 13° N.; that is, between about 3° north and 3° south of the magnetic equator. Records were taken with a simple temperature-compensated variometer, and were supplemented by frequent *QHM* readings. The whole period was relatively quiet magnetically, and the records at all stations included a number of quiet days.

The daily range of H, taken as the difference between the mean values for an hour around the times of maximum and minimum, was found for each station, and compared with that for the base station at Ibadan. Although the ratio of the ranges at the field and base stations varied considerably from day to day, the mean value of the ratio shows a smooth variation with latitude.

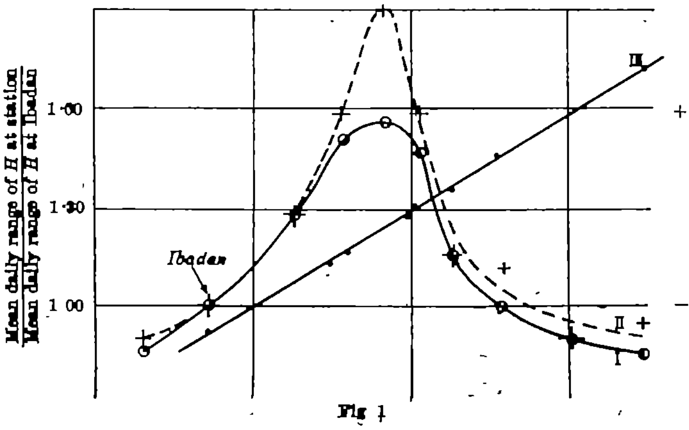

Fig 1

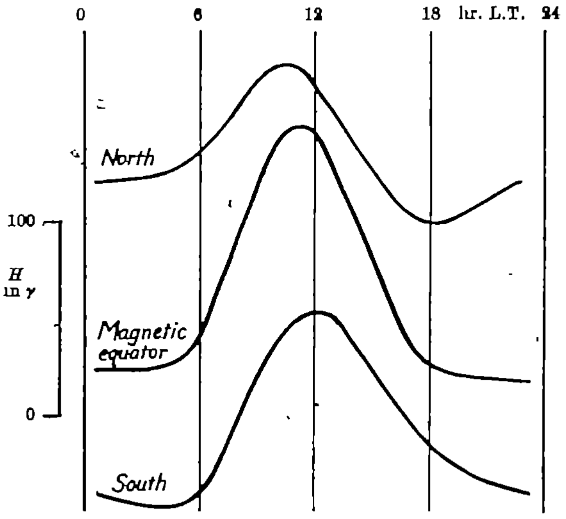

Fig 2

In Fig. 1, curve I shows the mean of the ratio for quiet days, curve II for all days, and curve III the magnetic dip, against latitude in each case.

It is clear that, at the December solstice at least, the region of maximum range of H is about 0·5° south of the magnetic equator. The curve shows some asymmetry about this maximum. Under quiet conditions the maximum range is about 1·8 times that at stations only 3° to the north or south.

The form of the daily variation curve also varies markedly with latitude. Fig. 2 shows this, each curve being the mean of six days. South of the magnetic equator there is a rapid rise from a minimum at about 0500 hr. (local time) to a maximum at 1200 hr., followed by a slow decline; close to the magnetic equator the curve is symmetrical with a maximum at 1100 hr.; and to the north there is a slow rise from midnight to a maximum at about 1000 hr., followed by a rapid decline to a minimum at about 1800 hr.

If the degree of asymmetry A is expressed as the difference between the values at 0500 and 1800 hr. divided by the daily range, A is found to vary linearly with latitude.

It does not seem possible to explain these changes in the form of the daily variation curve in terms of a lunar influence on a solar diurnal variation. It is suggested that a satisfactory explanation can be found in the superposition of the effects of a narrow equatorial electro-jet, localized at the magnetic equator or very near it, on a more general field which varies appreciably with latitude in phase and probably in magnitude.

On many occasions even on quiet days, fluctuations in H are observed which are coincident in time and similar in form at the base- and field-stations; these appear similar to those reported by Chapman and Bartels[1]. The amplitude of these fluctuations at a station 0·5° south of the position of maximum daily range has a mean ratio of 1·80 to that at the base-station. As this is higher than the ratio of the daily ranges at the stations, it suggests that whereas the daily range may result from a superposition of the jet effect on a general field, the fluctuations arise mainly from minor fluctuations of the electro-jet itself.

The rapid change in daily range with latitude indicates that the equatorial electro-jet must be very narrow, probably about 2–3° (200–300 km.) wide. This is supported by the anomalously large diurnal variation in the vertical component Z of the magnetic field at Ibadan. The mean quiet-day range in Z varies seasonally from about 40γ to 80γ, and is fairly constantly about 0·6 of the daily range of H. This indicates an origin in a current system the 'centre of gravity' of which is well to the north. Ibadan appears to be not directly under the electro-jet, but sufficiently close to it for its effects to predominate in the daily variation.

A parallel investigation of the variation of Z with latitude is being undertaken shortly, and it is hoped that this will give more detailed information on the location and extent of the equatorial electro-jet.

Full details will be published shortly.

A Frequency Comparator using Electron and Proton Resonance in a Common Magnetic Field

High microwave frequencies may, with advantage, be measured by utilizing electron and proton paramagnetic resonances in a common magnetic field. For this purpose the free radical diphenyl trinitrophenyl hydrazyl, which has one of the strongest and narrowest lines yet reported[1], is suitable for the electron resonance sample. The protons in water containing a trace of a paramagnetic salt provide the most suitable substance for the proton resonance.

The method of frequency measurement at, say, 35,000 Mc./s. is as follows. The magnetic field is varied until a signal is observed, from the electron resonance. This will be at about 12,000 gauss. This field is then measured by means of a proton resonance fluxmeter. If the common magnetic field is swept through a small range in synchronism with the X-deflexion of a cathode ray tube, it is possible to superimpose the proton and electron signal with considerable precision despite small instabilities in the magnetic field.

When this has been done the ratio of the two frequencies depends on the ratio of the two gyromagnetic ratios $\gamma_e/\gamma_p \simeq 658 \cdot 5$. In this way a conventional high grade signal generator employing quartz crystal calibration points may be used to read the lower frequency; and by means of the multiplying factor 658·5, converted to the microwave frequency. Alternatively a quartz harmonic generator may be used, of fundamental frequency $10^n/658 \cdot 5$ Mc./s., and this will provide markers at 10^n Mc./s. intervals, where n is a convenient integer.

The accuracy of the system has yet to be more fully investigated, but it would appear that the most fundamental limitation is the rather wide line of polycrystalline hydrazyl. This has a width of 8 Mc./s. so the setting accuracy would be of the order of 0·8 Mc./s. However, there may be better materials available, such as aminophenyl-aminium perchlorate, which is reported[2] as having a line width of about 1 Mc./s. Sodium in ammonia[3] could also be used but has practical difficulties. Its line width is reported as about 0·2 Mc./s. Another very practical limitation is the uniformity of the magnetic field required to render the field common to both specimens in space (or the stability required for the exchange to take place in time). The most promising method would appear to be to exchange the relative positions of electron and proton sample and take the mean of two or more observations. It is expected that the accuracy to which γ_e/γ_p is known will improve as work proceeds.

This communication is published with the permission of the Admiralty.

Use of 'Nobecutane' in attaching Skin Electrodes

In routine physiological experimentation, various types of electrodes are used attached to the surface of the body. These are commonly attached by rubber bands, strips of adhesive plaster or some kind of cement. At the R.A.F. Institute of Aviation Medicine, three types of electrode are being used which require a special method of attachment.

(1) For routine electrocardiograms in the acceleration research department, small silver disks 1·5 cm. in diameter are used attached to the front of the chest for the V-leads and to the back for the Duchosal and Sulzer method in vector cardiography. Contact with the skin is limited to the circumference of the disk, the centre position being recessed and containing electrode jelly. These electrodes and their leads are subjected to fairly severe strain when the subject is having accelerations of up to 7G applied. An adhesive was required which would hold the electrode firmly in position and yet allow movement of the part and withstand a fair pulling strain.

(2) In the climatic research unit, experiments required the attachment of heat-flow disks and thermocouples to the skin which would be submerged in water, thus a strong adhesive with waterproof qualities was essential. After trying several methods of attachment a trial using 'Nobecutane' was commenced.

For the attachment of electrocardiographic electrodes, 'Nobecutane' proved highly satisfactory. The electrodes were quickly applied and the time spent in preparing the subject was cut down considerably. The breaking strain of a film of 'Nobecutane' was tested by attaching an electrode to the volar aspect of the forearm with a film of 'Nobecutane' 0·01 in. thick and adding weights until the electrode was detached. In five such tests, the weights required to pull off the electrode were 2·0–2·5 kgm.

In all, some fifty centrifuge runs have been carried out using electrodes stuck on with 'Nobecutane' without any pulling off. Some subjects have had electrodes attached to the flexure at the elbow for two days while performing their normal work and washing without any detachment. The best method of attaching the electrodes has been found to be by painting the circumference of the disk with 'Nobecutane' solution and fixing to the skin; when this has dried, the whole is given a film of 'Nobecutane', using the spray.

The experiments utilizing heat-flow disks and thermocouples required from six to eleven of each type of electrode to be attached to a subject, who was then immersed in a bath of water (temperature, 34–40° C.) for a period of 2–3 hr. The method used to attach the heat-flow disks was to place them in contact with the skin, cover with a layer of gauze and spray the latter with 'Nobecutane', thus leaving the heat-flow disk in a waterproof compartment. The thermocouples were placed in contact with the skin and 'Nobecutane' sprayed over them. To date, sixty such experiments have been carried out without detachment of any electrodes and there was no evidence of any leak of water. In some instances the thermocouples were covered with a pad of dry cotton-wool before being sprayed with 'Nobecutane' and at the termination of the experiment the cotton wool was still dry. An interesting point is that submersion of the subject before drying of the 'Nobecutane' made little difference in that the electrodes remained dry and attached.

Only one skin reaction has occurred in the series. This was a local urticarial reaction at the site of attachment of the electrocardiogram electrodes. However, when this subject was afterwards scratched with electrode jelly alone, a similar reaction occurred; thus it is unlikely the reaction is due to 'Nobecutane'.

Hence, it appears that 'Nobecutane' is a very satisfactory material for the rapid attachment of electrodes which are required to withstand strain, while for underwater electrodes it is the only substance so far encountered which will fulfil the necessary requirements.

The 'Nobecutane' for this trial was kindly supplied by Messrs. Evans Medical Supplies, Ltd.

Influence of Post-Irradiation Administration of Methionine on the Levels of Deoxyribonucleic Acid in Bone Marrow, Spleen and Liver of Rats

EXPERIMENTAL evidence has been accumulating in recent years to suggest an important role of methyl groups in the formation of nucleic acids. Among the principal sources of methyl groups for the animal organism are methionine and choline. The organism can synthesize the methyl groups from simple precursors, such as glycine, serine and 'formate'[1]. Studies from this laboratory[2] have demonstrated that methionine, which contains an active S-methyl group, is very radiolabile and is destroyed both in the *in vivo* and in the *in vitro* experiments, following exposure to ionizing radiations. Post-irradiation administration of spleen and bone marrow homogenates has been found to counteract the lethal and other biological effects of ionizing radiations in mice[3], and it has been postulated[4] that these act through a humoral agent present in the extracts. In view of these findings, coupled with our own results on radiolability of methionine, it was considered necessary to investigate if post-irradiation administration of methionine offered any protection at all against radiation exposures. Since impairment of nucleic acid synthesis following X-irradiation has been well established[5], any substance having a modifying influence on the primary radiation lesion should have a beneficial influence on the levels of nucleic acids. This criterion has been used here to assess the possible protection and therapeutic effects of methionine administered half an hour after total-body X-irradiation.

The experimental animals consisted of male Wistar albino inbred rats 2–2½ months old and weighing 200–250 gm. These were maintained on a standard laboratory diet and water *ad libitum*. The rats were given a single total body X-irradiation of 600 r., dorsal and ventral sides getting 300 r. each. A 'G. E. Maximar' deep-therapy unit, operated at 220 kV. and 10 m.amp. with 0·5 mm. copper and 1·0 mm. aluminium filters, was used for irradiating the animals. The distance of the animals from the target was about 35 cm. and the dose-rate was 50 r./min. in air as determined by a Victoreen dosimeter.

The rats were divided into five groups of six animals each. The first group served as controls, whereas the second group received methionine only (without irradiation) and the third group received 600 r. total-body X-ray irradiation only. In the second group, an aqueous solution of methionine (1 mgm./ml.) was injected intraperitoneally in a single dose of 5 mgm./kgm. body-weight, 24 hr. before killing. The animals of the fourth and fifth groups received total-body irradiation and in addition received 5 mgm./kgm. body-weight of methionine intraperitoneally 30 min. after and before irradiation respectively. The irradiated groups (3, 4 and 5) were killed 24 hr. after X-irradiation. Food was withheld overnight prior to killing in controls as well as in experimental animals. The rats were killed by ether inhalation, and the liver, spleen and bone marrow quickly dissected out and nucleic acids estimated by Schneider's modification[6] of Schmidt and Thannhauser's method[7], as described by Baxi *et al.* (*loc. cit.*). Phosphorus determinations were carried out by Fiske and Subbarow's method, as modified by LePage and Umbreit[8].

The results, giving the levels of deoxyribonucleic acid in liver, spleen and bone marrow in irradiated and methionine-treated irradiated rats, are given in Table 1. It will be noticed that the total-body X-irradiation brings about a fall in levels of deoxyribonucleic acid in all the tissues studied and that

Table 1. INFLUENCE OF ADMINISTRATION OF METHIONINE ON THE LEVELS OF DEOXYRIBONUCLEIC ACID IN BONE MARROW, SPLEEN AND LIVER OF IRRADIATED RATS

Nucleic acids expressed as mgm. P/100 gm. wet weight

Group	Liver	Spleen	Bone marrow
Controls	19·40	95·50	256·0
Methionine group	17·80	89·60	228·0
X-irradiated group	16·80	25·90	31·60
X-rays + methionine (½ hr. after)	23·80	46·20	126·6
X-rays + methionine (½ hr. before)	23·20	37·30	89·3

the administration of methionine either before or after irradiation is able to check the fall to some extent. Post-irradiation administration of methionine, however, appears to be more effective in this respect. The fall in level of deoxyribonucleic acid in post-irradiation methionine-treated animals was 50·6 and 51·6 per cent respectively in bone marrow and spleen. The corresponding figures for irradiated animals without the methionine treatment of group 3 were 87·9 and 71·8 per cent. The fact that the post-irradiation administration of methionine is more effective in arresting the fall in nucleic acids levels caused by exposure to radiation than the pre-irradiation treatment can be explained on the basis of the radiolability of methionine reported previously[8].

In a previous communication from this laboratory (Baxi *et al.*, *loc. cit.*), it was suggested that irradiation causes depletion of nucleic acid levels in two ways: (1) by destruction of preformed cells with a consequent catabolism of nucleic acids contained in them; and (2) by impairment of the nucleic acid synthesizing mechanism itself. Methionine has been known to play a dual part in the body, first by aiding transmethylation processes, and secondly by participating in the synthesis of creatine and thus influencing the process of phosphorylation. Since both these processes are vital for the synthesis of nucleic acids, it appears likely that replacement of methionine helps in keeping the nucleic acid synthesizing mechanism in order and thus exerts a therapeutic influence on radiation injury.

Effect of Angiotonin on the Distribution of Sodium, Potassium and Water in the Rat

STUDIES of 'Pitressin' in the bilaterally nephrectomized rat have shown that this extract causes a shift of sodium and water out of the extracellular fluid while potassium moves in[1]. These movements are related to the pressor effect of the extract. Similar shifts are also associated with the pressor effects of epinephrine and norepinephrine[2,3]. With all these agents, reverse shifts occur during the decline of the blood pressure back to normal. Based on our interpretation of these and other similar experiments, we have suggested the theory that the regulation of blood pressure depends, *inter alia*, on the sodium transfer systems[4]. We have considered potassium to be of less importance than sodium in this regulation, since shifts of this ion are usually considerably less in total amount. This idea is supported by the present findings with angiotonin (hypertensin) in which sodium shifts were not accompanied by any inverse shift of potassium.

The pressor effect of angiotonin is known to be magnified by previous (at least 24 hr.) nephrectomy. Thus, all rats in these experiments were bilaterally nephrectomized and only 24 hr. later received inulin (12 mgm./100 gm., for measurement of extracellular fluid volume) intravenously. After two hours of equilibration, a basal femoral artery blood sample (0·6 ml.) was obtained, the test agent injected and two further blood samples taken. Samples were analysed chemically for inulin[5] and for sodium and potassium by flame photometry. A continuous femoral artery blood-pressure was recorded electromanometrically.

In the first experiment, 10 units of angiotonin in 0·2 ml. of saline was infused over a 30-sec. interval in a test group of 10 rats; saline alone in 10 controls. The second blood sample was drawn 20 sec. after the start of the infusion while the pressure was rising, the third at 50 sec., at the peak of the pressure curve. The second experiment was identical except that blood was drawn at 80 and 120 sec., on the falling curve of pressure. Fig. 1 shows that blood pressure and extracellular sodium form inverse curves. Potassium did not shift.

The third experiment was similar except that 50 mU. 'Pitressin' was infused. The second blood sample was taken at 50 sec., the third at 90 sec.—points on the rising curve of blood pressure comparable with those in the first angiotonin experiment. Table 1 compares the results with 'Pitressin' and angiotonin. Both agents clearly shift sodium and water out of extracellular fluid but differ in their effect on potassium since this ion is unaffected by

Metabolism and Metabolic Effects of Thyroglobulin

INJECTION of beef or hog thyroglobulin into experimental animals causes an increase in basal metabolic rate and antagonizes the action of antithyroid drugs. These effects are similar to those following the injection of thyroxine. There is yet no adequate explanation for the fact, reported by various workers[1], that these thyroglobulins are more effective than can be accounted for by the liberation in the body of the thyroxine they contain. More recent observations have demonstrated the varying ability of different species to remove homologous and heterologous thyroglobulins labelled with iodine-131 from the circulation[2]. An attempt is now being made to correlate the metabolism of different thyroglobulins with effect on the basal metabolic rate at the same dose-level. This communication concerns the absorption, metabolism and metabolic effects in the rabbit of purified dog thyroglobulin.

The thyroglobulin was prepared by fractional precipitation of gland extracts with ammonium sulphate, the final solution being freeze-dried. For use it was diluted with a suitable amount of similarly purified material, labelled *in vivo* by administration of iodine-131. The relevant analytical data were as follows:

Iodine content (Leipert method) 0·6 per cent
Iodinated components (determined by a combination of proteolysis and chromatography)

Thyroxine	14·0 per cent
Tri-iodothyronine	1·7 ,,
Di-iodotyrosine	47·0 ,,
Mono-iodotyrosine	33·0 ,,
Iodide	3·5 ,,
Unhydrolysed material	1·8 ,,

Fig. 1 shows the plasma levels of radioactivity after administration of the labelled dog thyroglobulin (50 mgm./kgm.) by various routes, and Fig. 2 represents the corresponding effects on the basal metabolic rate. Absorption of the protein from the peritoneal cavity was rapid (95 per cent of the dose appeared in the plasma after 5 hr.) and the rate of clearance of radioactive material from the blood thereafter was similar to that following intravenous injection (Fig. 1). From a subcutaneous site, however, radioactive protein entered the circulation at a very slow rate, so that a peak value of about 30 per

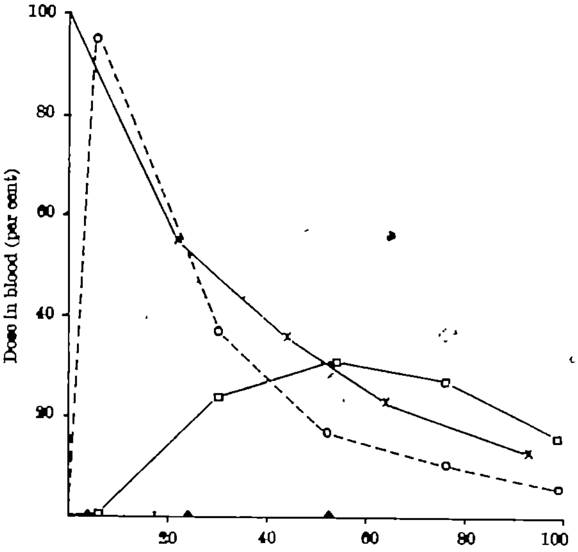

Fig. 1. Plasma levels of radioactivity in rabbits after administration of labelled dog thyroglobulin (50 mgm./kgm.) by various routes: ×- - -×, intravenous; □——□, subcutaneous; ○——○, intraperitoneal; △——△, oral

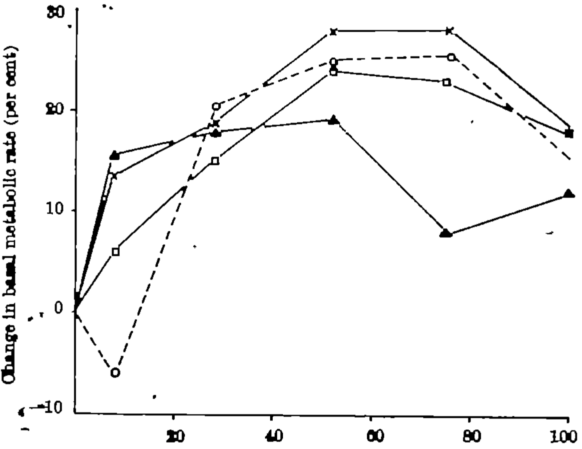

Fig. 2. Changes in the basal metabolic rate produced in rabbits by dog thyroglobulin administered by various routes: ×——×, intravenous; □——□, subcutaneous; ○- - -○, intraperitoneal; △——△, oral

cent of that injected was present in the blood two to three days later. No radioactive protein appeared in the plasma from the oral route—indeed the maximum amount of radioactivity found in the circulation (at 4 hr.) was less than 0·4 per cent of the dose given, and consisted of a mixture of iodide and thyroxine (3 : 1). After parenteral administration, however, the circulating material remained indistinguishable from thyroglobulin using paper chromatography, and only traces of metabolites (iodide and thyroxine) were detected. Since the rabbits were not thyroidectomized, a proportion of the minute amount of labelled thyroxine present must have been due to a turnover of radioactive iodide by the gland. On the whole, the basal metabolic rate rise began on the day of administration of the thyroglobulin (Fig. 2). After intravenous, intraperitoneal and subcutaneous injection, the course of events was very similar, with a maximum increase of 25–30 per cent in about two days, slowly declining after three to four days. Oral administration of the thyroid protein produced a similar but less consistent rise in oxygen consumption. A comparable dose of purified plasma globulins (50 mgm./kgm.) had no effect on the basal metabolic rate, so that the possibility of a non-specific effect seems remote.

These experiments have demonstrated that a prolonged rise in metabolic rate follows the administration of dog thyroglobulin to rabbits. It is curious that the increase in oxygen consumption does not appear to be directly related to the plasma-level of thyroglobulin or to the liberation into the plasma of the thyroxine derived from it. About 0·5 mgm./kgm. of L-thyroxine was required to produce a comparable rise in basal metabolic rate when given intravenously. The total amount of this substance in the protein was 0·1 mgm./kgm., of which less than 1 per cent could be accounted for in the plasma at any time. It may be argued that the slow degradation of thyroglobulin after injection and the steady liberation of its combined thyroxine are a more effective way of stimulating the basal metabolic rate. However, the very small quantity of hormone detectable in the circulation (2 or 3 μgm. per animal) is difficult to reconcile with the effect on the metabolic rate. Moreover, the minute proportion of labelled thyroxine in the plasma persisted while the metabolic rate returned to normal levels.

Detailed results of these experiments and of studies with other thyroglobulins will be published elsewhere.

An Acetylcholine-like Salivary Poison in the Marine Gastropod *Neptunea antiqua*

IN *Neptunea antiqua* the salivary glands are large organs weighing 1–3 gm. (Fig. 1). The fresh glands have a peculiar intense smell, probably due to the presence of volatile amines. Extracts of the glands (made with water, acetone or ethanol) have a strong contracting effect on smooth muscle. When a dose corresponding to about 1 : 100 of a gland was injected into small fishes (*Ctenolabrus*, *Gadus*) or mice, the animals died within a few minutes. When somewhat smaller doses were injected intraperitoneally into mice, the animals survived but developed symptoms of heavy stimulation of the parasympathetic system: a profuse secretion of saliva and tears. The secretion could be abolished by atropine. Glandular extracts were tested on the heart of *Cyprina*[1] or the isolated radula-muscle of *Buccinum*[2] and were found to produce acetylcholine-like effects corresponding to a concentration of acetylcholine of about 10^{-8} gm./ml. Unlike acetylcholine solutions the extracts did not lose their physiological effects by short boiling at pH 9 or by the addition of acetylcholine esterase (a drop of human blood). Paper chromatography showed a very distinct spot which was stained brick-red by dipicrylamine[3] and had an R_F-value between choline and acetylcholine. Sometimes it was difficult to distinguish this spot from a spot produced by choline. The spot could also be identified by exposure to iodine vapours or by pharmacological testing of strips of the filter paper.

In the related species *Buccinum* the salivary glands contain a substance resembling 5-hydroxytryptamine[4], but no such substance could be demonstrated in extracts of the *Neptunea* glands. Murexine, the choline ester found in the hypobranchial gland of

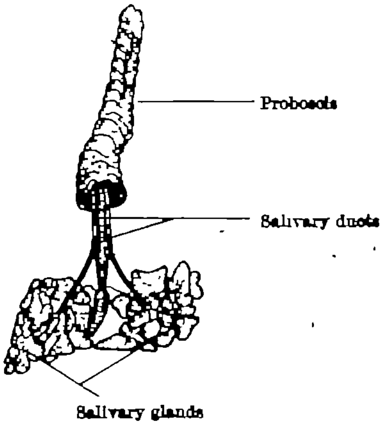

Fig. 1. Proboscis and salivary glands of *Neptunea antiqua*. The two secretory ducts follow the oesophagus and open into the mouth at the tip of the proboscis. About one-quarter natural size

Murex trunculus, has strong nicotine-like effects but almost no muscarinic effects[5]. For that reason the physiological effects from extracts of the *Neptunea* glands probably are not due to the presence of murexine. In Hokkaido in Japan food poisoning has been caused by eating *Neptunea arthritica*, and it was found that only the salivary glands and no other parts of the molluscs were poisonous[6].

Neptunea, like *Buccinum*, is a carnivorous animal, but its feeding habits are not known. Presumably, the secretion from the salivary glands is used to paralyse other animals which serve it as prey.

Action of Copper on Mammalian β-Glucuronidase

IN studying the inhibition of partially purified mammalian β-glucuronidase by heavy metal ions, we have found that the cupric ion is a moderate inhibitor, and is potentiated by cysteine. This action of cysteine appears to be limited by the formation of cystine, since the latter reverses inhibition by copper and by other metals. Sodium bisulphite and ascorbic acid were therefore examined as alternative reducing agents. Neither of these agents by itself had any effect on the enzyme activity, but they had an identical action in potentiating inhibition by the cupric ion, as shown in Fig. 1; this process was instantaneous, there being no increase in inhibition on prolonged incubation with the substrate. In the presence of ascorbic acid or bisulphite, the inhibitory power of Cu^{++} was of the same order as that of Ag^+ or Hg^{++}, neither of which was potentiated by the reducing agents. A feasible explanation of these results is that copper inhibition is due to the cuprous, and not the cupric, ion.

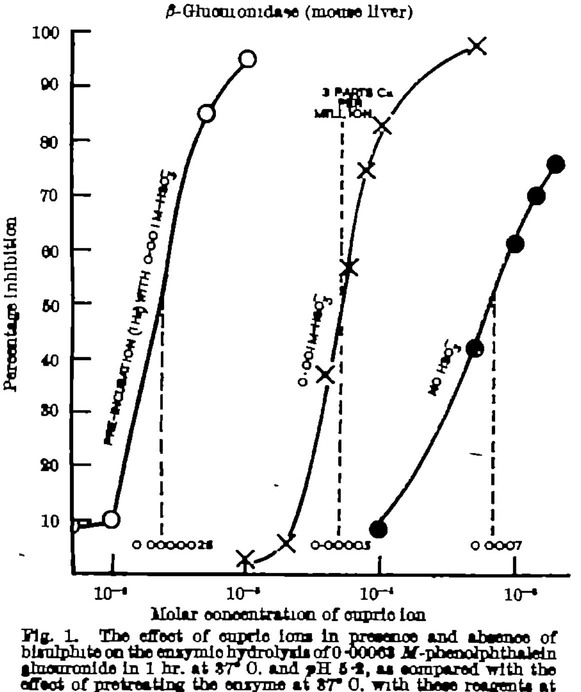

Fig. 1. The effect of cupric ions in presence and absence of bisulphite on the enzymic hydrolysis of 0·00063 *M*-phenolphthalein glucuronide in 1 hr. at 37° C. and *p*H 5·2, as compared with the effect of pretreating the enzyme at 37° C. with these reagents at the *p*H of assay

These experiments may explain conflicting statements in the literature on inhibition of β-glucuronidase by ascorbic acid[1], and may have some bearing on the inhibition of sulphatase by bisulphite[2].

When the enzyme β-glucuronidase was incubated in the presence of cupric ions and bisulphite at 37° C. for 1 hr. prior to addition of substrate for assay, the inhibition was enormously increased (Fig. 1). It was necessary to incubate all three components, enzyme, cupric ion and bisulphite, simultaneously, and the process was arrested by addition of substrate. The inhibitory power of Ag^+ and Hg^{++} was also increased in this type of experiment, but ascorbic acid could not replace bisulphite in this reaction. It is concluded that we are measuring here an alteration in the actual enzyme molecule.

Structure of Brain Ganglioside

THE brain gangliosides of Klenk[1] are macromolecular glycolipids of unknown structure and function, composed of neuraminic acid, sphingosine, fatty acids, hexoses and a hexosamine[1–4]. Structural evidence has now been obtained by acid hydrolytic cleavage of a highly purified preparation of brain ganglioside. A glucocerebroside has been isolated and the structure of the repeating unit formulated.

A stepwise procedure has been developed by which small fragments are successively cleaved from the water-soluble macromolecule, and separated quantitatively and gently from the balance of the molecule by exhaustive dialysis through 'Cellophane'. Both the dialysable and non-dialysable hydrolytic products are analysed at each step in terms of dry weight, titratable acidity, nitrogen, amino-nitrogen, neuraminic acid, hexosamine, hexose, and reducing sugar, partitioned by paper chromatographic and ion-exchange procedures, and the subfractions further hydrolysed and analysed. Earlier studies[2,3] have demonstrated the hexoses to be exclusively glucose and galactose, and the hexosamine to be galactosamine.

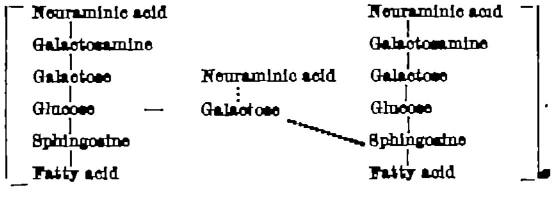
In the present work, bovine brain ganglioside was prepared[2,3] as an ash-free fraction (I) homogeneous by electrophoretic and ultracentrifuge studies (minimal molecular weight 250,000), completely water-soluble, free of phosphatides (P, 0·07 per cent) and of dialysable contaminants. (I) contains nitrogen 2·9 per cent, hexose 24·0 per cent (expressed as galactose) and galactosamine 10·0 per cent.

A 2 per cent aqueous solution of (I) is autohydrolysed at 100° C. for a critical time interval of

25 min., then exhaustively dialysed. The dialysate contains 66 per cent of the neuraminic acid and 5·2 per cent of the galactosamine of (I). The non-dialysable residue (*A*) accounts for 80 per cent by weight of (I). When (*A*) is hydrolysed (0·09 hydrochloric acid, 100° C., 50 min.), then dialysed exhaustively, the dialysate contains a further 8 per cent of the neuraminic acid, 24·2 per cent of the galactosamine, and 15 per cent of the hexose (galactose exclusively) of (I). The water-soluble non-dialysable residue (*B*) accounts for 64 per cent by weight of (I). When (*B*) is hydrolysed (6 *N* hydrochloric acid, 100° C., 5 min.), then dialysed, the balance of the neuraminic acid, galactosamine and galactose, plus some glucose, become dialysable. The non-dialysable residue contains the sphingosine and fatty acid of (I) plus 8 per cent of the hexose (glucose only). The recovery in terms of hexose and nitrogen, taking all the subfractions together, has been 96·6 and 96 per cent respectively.

The hydrolysis of (*A*), which removed galactose but no glucose, suggested that an intact glucocerebroside might be isolated. Optimal conditions were defined as follows: (*A*) is hydrolysed with 0·09 *N* hydrochloric acid (sealed tube, 100° C., 16 hr.), then dialysed. The resulting non-dialysable residue (*C*), still water-soluble, is further hydrolysed (0·09 *N* hydrochloric acid, sealed tube, 100° C., 5 hr.). The hydrolysate, which now contains a tan-insoluble material, is dialysed. The water-insoluble material is separated by centrifugation and dried *in vacuo*. It is soluble in warm methanol/chloroform (9 : 1), from which it forms birefringent spherocrystals on cooling (25° C.). To date, yields of these crystals represent between 26 and 30 per cent by weight of (I). The crystals contain nitrogen 1·8 per cent, and hexose 21·8 per cent (expressed as glucose). Neuraminic acid and galactosamine are absent. Their infra-red spectrum is consistent with that of a cerebroside. Hydrolysis of a glucocerebroside would yield glucose plus a ceramide. Hydrolysis of the crystals (1 *N* hydrochloric acid, sealed tube, 100° C., 16 hr.) liberates the hexose (exclusively glucose). The remaining water-insoluble residue contains nitrogen 2·3 per cent, as expected for a ceramide.

The constant order of release of dialysable constituents observed in repeated stepwise hydrolyses, namely, neuraminic acid, galactosamine, galactose, glucose, sphingosine and fatty acids, is suggestive of a structural sequence. Furthermore, analysis of aliquots of the hydrolytic products at particular steps revealed, in addition to a glucocerebroside, fragments of fatty acid–sphingosine, sphingosine–glucose, hexose–galactosamine and galactosamine–neuraminic acid. These and other results suggest that the repeating unit of this brain ganglioside is as follows:



Constituent (per cent) of brain ganglioside

	Calculated on the basis of the above formulation	Found
Nitrogen	2·96	2·9
Neuraminic acid	30 5	30·3
Hexose	24·4	24 0
Galactosamine	10·8	10 0

The linkages which have not yet been positively identified are shown by dotted lines. There is evidence that the constituent cerebroside base is modified in that it possesses a free reducing group, and that it is by means of glycosidic bonding between this group and a hexose of the neighbouring repeating unit that the polymerized macromolecule is formed.

The above structure, with water-soluble constituents 'facing' one way, and lipid-soluble constituents 'facing' the other, would permit the brain ganglioside to function admirably in transport phenomena occurring at the nerve cell surface. A detailed report of this work will appear elsewhere.

Determination of the Sex of Human Abortions by Nuclear Sexing the Cells of the Chorionic Villi

Barr and Bertram[1] demonstrated the almost invariable presence of a specific body in the cells of the hypoglossal nuclei of female cats. The subsequent literature on the subject is large and has been very clearly reviewed by Lennox[2]. It seems possible that the technique of sexing cells now available may contribute to the difficult problem of determining the sex ratio in human abortions, and so indirectly to that of the early sex ratio in man. The traditional view that, so far back as can be determined, the male to female sex ratio rises has recently been questioned. Further, only a relatively small proportion, perhaps 10 per cent of embryos of sexable age, can be recovered in human abortions; so that even in respect of embryos larger than 17 mm. direct sexing must be extremely slow and laborious.

The question of the sex ratio from conception onwards in man is of more than academic interest at the present time, in that reasonably accurate estimates of early ratios are essential for estimating the validity of extrapolations from experimental animals to man of the importance of sex-linked lethal mutations to be expected from increased exposure to radiation.

In a high proportion of human abortions, chorionic villi can be found even in decidual scrapings recovered at curettage carried out to ensure that debris are not left in the uterus after an abortion. Fortunately, even if the decidua is necrotic, the embedded villi seem to remain viable. Such live villi with cells having nuclei which stain perfectly are often present in our experience for so long as three weeks after the main products of conception have been lost.

A series of sections of placentae of mature children of known sex were examined, and it was demonstrated that it was possible to determine accurately the sex of the child by the presence or absence of 'sex chromatin' in the nuclei of the cells of the supporting tissue of mesenchymal origin in the placental villi.

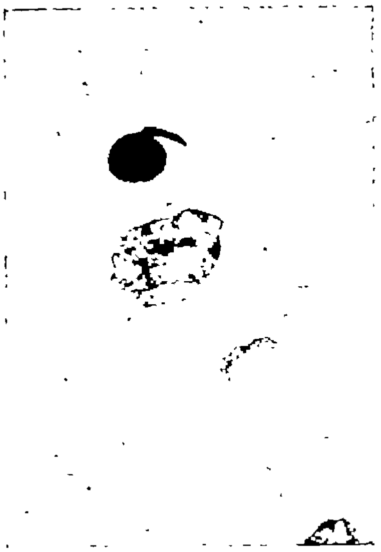

Fig. 1

More important and relevant, it has also proved possible to 'sex' chorionic villi recovered from abortions at all periods of pregnancy, using the nuclei of mesenchyme cells in the supporting tissue of the villi. The nuclei of the syncytial cells and of the cytotrophoblastic Langhan's cells covering the villi have proved relatively unsuitable for the purpose, as they tend to have a very large chromatin content in the nuclei; this makes determination of the pattern inside the nucleus difficult. In addition, the Langhan's cells often overlap in cut sections.

So far, only one hundred and thirty abortions have been examined in the Department. On average, however, between four and five specimens are being received daily from two units which treat all the abortions that occur in Belfast with the exception of the odd case admitted in error or occurring accidentally in other hospitals. It is hoped that, by the end of the present year, a sufficient number will have been examined to be of value in relation to the question of sex ratio, at least in respect of abortions occurring in the eight- to twelve-week period which is the most common duration of pregnancy at which abortions occur. Concurrently, intensive recording of case fertility and family history is proceeding in respect of each abortion.

Specimens are fixed in the formalin, alcohol acetic acid fixative recommended by Moore and Barr[3], and sections are stained as a routine by hæmatoxylin and eosin and by the ribonuclease gallocyanin method[4]. The former is essential for proper identification of tissues and is usually adequate for identification of nuclear detail, provided the sections are well cleared of acid and lightly stained.

Fig. 1 shows a villus mesenchyme cell with typical 'sex chromatin' lying against the nuclear membrane. The woman had had a sharp loss of blood and clot at nine weeks, and probably lost most of the products of conception at that time. She did not, however, consult a medical practitioner; in hospital, curettage revealed only degenerate decidual tissue and a few villi. More than 90 per cent of the nuclei of villus cells counted showed unmistakable sex chromatin.

We are indebted to Prof. J. H. Biggart, who provided sections of placenta from children of known sex, so that our recognition could be checked, and to Dr. J. G. Gibson for much help and advice.

Isolation and Cultivation of Zooxanthellae

A remarkable characteristic of tropical coral reefs, and indeed to some extent of shallow marine waters everywhere, is the profusion of single-cell, yellow-green algae (the so-called symbiotic zooxanthellae) that live within a wide variety of radiolarians, coelenterates, molluscs, bryozoans, worms, ascidians, etc. With a few exceptions, the definite taxonomic status of zooxanthellae has been difficult because of their somewhat generalized morphology and because of the absence or elusive nature of a motile phase[1-3]; only Kawaguti[4] has reported seeing motile forms.

If, following on the work of Kawaguti, zooxanthellae could be isolated from host animals, grown serially in bacteria-free culture, and their nutritive and reproductive characteristics studied *in vitro*, not only should their identity in each case be ascertainable, but also possibly clues as to their trophic relation with the host.

We have approached the problem from this point of view, using variations of recently developed synthetic marine media[5], together with special isolation techniques. Hitherto, we have succeeded in culturing through serial passage zooxanthellae from a nudibranch (*Scyllaea* sp.), a Scyphozoan jelly-fish (*Cassiopeia* sp.), and an anemone (*Condylactis* sp.), all common forms collected in waters around Bimini, British West Indies.

The initial inoculum was either a fragment of zooxanthellae-containing host tissue or, more frequently, a suspension of zooxanthellae removed from such tissue by maceration in a Waring blendor, then centrifuged, and repeatedly washed in solutions of sterile sea water and of defined antibiotic-treated media. In the medium presently employed, inocula of 5–10,000 vegetative cells regularly show an absolute increment within 15 days to about 30 million.

Motile phases were never observed among zooxanthellae freshly taken from the host's tissue, nor in the host's enteric fluids. However, after one to four weeks in continuous low light, many algal cells of the inoculated culture tubes gave rise to motile forms the concentration of which at times reached 'bloom' proportions. Motile cells derived from *Scyllaea*, *Cassiopeia*, and *Condylactis* zooxanthellae were unequivocally observed to be flagellates of the Dinophyceæ group, that is, they showed (*a*) a transverse girdle, (*b*) two flagella, one enclosed in the girdle and the other extending backwards, (*c*) a characteristic spiral motility. *In vitro* reversion of motile cells to the vegetative type was observed repeatedly, and successive transfers are now routine in our laboratory.

Identification of these zooxanthellae as dinoflagellates supports earlier conclusions of Hovasse[6] and of Pringsheim[7] for corals based tentatively on the morphology of resting cells, and of Kawaguti[4], also for coral zooxanthellae, based on observation of motile cells. On the other hand, whether zooxanthellae of all algae-harbouring animals fall into one or into multiple taxonomic groups, may not yet be said, nor whether they vary according to the season of the year or to local conditions.

Being able now to grow zooxanthellae serially *in vitro* suggests an avenue toward the possible resolution of some nutritive and general ecological problems pertaining to this widespread, perhaps fundamental plant–animal relationship. Work in this direction, as well as on the ecological distribution of zooxanthellae, continues. Details of the isolation and serial culture of the zooxanthellae described above will be published elsewhere[6].

We are grateful to Dr. C. M. Breder, director of the Lerner Marine Laboratory, Bimini, B.W.I., for having made the facilities of that institution available to us. We wish to express our thanks to the National Geographic Society of Washington, D.C., for having aided in field work which led to the initiation and development of this programme.

Leaching of a Flower Inhibitor from Late Varieties of Peas

Barber and Paton[1,2] concluded from grafting experiments between genetically early and late varieties of garden peas (*Pisum sativum*) that the dominant *Sn* gene causing late flowering is responsible for the production of a substance delaying flowering. This inhibitor passes into the plumule from the cotyledons over a period of 10–14 days after germination. Cuttings taken soon after germination usually flower at a lower node than those taken later, or than whole plants. This effect is most marked in short-days, since the delay in flowering produced by the *Sn* gene is the greater the shorter the photoperiod (Barber and Sprent, unpublished work).

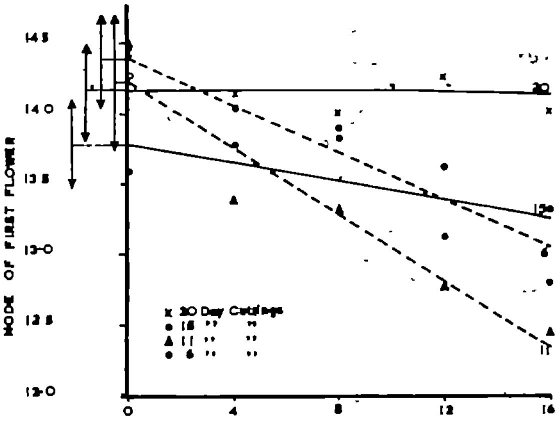

Fig. 1. Regression lines of node of first flower on leaching time for different cutting dates. Arrows indicate the 95 per cent confidence limits of the intercepts made by the lines on the *y*-axis

Table 1

Effect	Sum of squares	Degrees of freedom	Mean squares	*F* ratio	Significance level
Cutting date	10·49	3	3·96	14·82	0·1 per cent
Leaching time	11·92	4	2·98	12·63	0·1 "
Interaction	8·61	12	0·72	3·04	1·0 "
Error	18·15	76	0·24	—	—

Numerous attempts using cuttings for bioassay have been made in order to isolate the inhibitor-hormone. These attempts have involved soaking young cuttings in weak solutions of a variety of chemical substances. In some of the experiments it has been noticed that controls soaked in water flower at a lower node than those planted directly in the soil. This effect was investigated further using the late variety Greenfeast in a factorial experiment combining cuttings taken at 6, 11, 15 and 20 days after germination and soaked in water for 0, 4, 8, 12 or 16 days before planting into the soil. The experiment was carried out in summer under natural photoperiod (about 16 hr.). The results for node of first flower are shown in Fig. 1, with the analysis of variance in Table 1. It is clear that the leaching of young cuttings leads to flowering at a lower node.

In order to analyse the effect more precisely, regression lines of node of first flower on time of leaching are given in Fig. 1 and the regression analysis of variance in Table 2. The slopes of the regression lines show that the leaching effect is greatest if the cuttings are taken 6–11 days after germination (at this stage two to four internodes are fully expanded). These relationships are, of course, responsible for the significant interaction between time of leaching and date of cutting.

In addition to node of first flower, the cuttings were scored for vegetative growth as measured by shoot-length, number of expanded internodes, node at which the first leaf with four leaflets is produced and on an arbitrary general growth scale. No correlation of any of these quantities with node of first flower was observed. The results, therefore, are best explained by the leaching out of a flower-inhibitor which is still in a labile phase following transport from the cotyledons. After 15–20 days from germination, the inhibitor becomes incorporated into the cytoplasm and can no longer be removed. At this stage soaking in water has no effect on flowering of cuttings. Analyses to identify the substances leached out of the young cuttings are being carried out.

Table 2 REGRESSION ANALYSIS OF VARIANCE

Type of cuttings	Effect	Degrees of freedom	Mean squares	Significance level
6 day	Regression	1	4·41	0·1 per cent
	Deviations	3	0·63	5·0 "

Partial Enzymic Degradation of *Tamarindus*-Amyloid

Heated cellulase of *Myrothecium verrucaria*[1] degrades the amyloid of *Tamarindus indica* to a product which by means of paper chromatography (applying butanol/pyridine/water/benzene (5 : 3·2 : 3 : 0·45) as a solvent and developing for a week) appears to contain at least eight oligosaccharides, three of them occurring as the main products. These three oligosaccharides, *A*, *B* and *C*, could be shown to be a hepta-, an octa- and a nona-saccharide respectively, and are composed of 4 glucose residues, 3 xylose residues and 0, 1 and 2 galactose residues respectively. They are liberated in a molar ratio of roughly 2 : 5 : 6. The three oligosaccharides constitute a homologous series; this was confirmed by the facts that: (1) the values of log $R_F/(1-R_F)$ lie on a straight line when plotted against degree of polymerization[1], and (2) the values of $[M]n/n$, when plotted against $(n-1)/n$, lie on a straight line as well[2].

Amyloids from seeds of other plant species can also be hydrolysed by cellulase. On paper chromatograms the oligosaccharides from the amyloids investigated (from *Tropaeolum majus*, *Cyclamen* hybr., *Impatiens balsamina*, *Hymenaea courbaril*, *Schotia latifolia*) have mobilities which suggest that in all instances the oligosaccharides are the same as those from the amyloid of *Tamarindus*. The ratios in which the oligosaccharides appear are different for different species. *Tropaeolum* amyloid is hydrolysed by cellulase to give the three oligosaccharides in a molar ratio of roughly 1 : 2 : 10. *Cyclamen* amyloid gives the oligosaccharides *A*, *B*, *C*, and *D* in a molar ratio of approximately 2 : 7 : 2 : 2. (Oligosaccharide *D* occurs in cellulase hydrolysates of *Tamarindus* and *Tropaeolum* amyloids only in negligible amounts, whereas in *Cyclamen* amyloid the amount is much larger.)

The specific rotations of the oligosaccharides *C* from the amyloids of *Tamarindus*, *Tropaeolum* and *Cyclamen* are: $[\alpha]_D^{18^\circ C.}$ = 73·0°, 74·6° and 75·6° respectively (c = 1, water). The correspondence of the specific rotations and of the chromatographic behaviour of the oligosaccharides *C* suggests that they are identical. Oligosaccharides *A* may also be identical, as well as the oligosaccharides *B*.

It is apparent that the amyloids of seeds have constitutions which are highly interrelated.

Details of this work will be published elsewhere.

Formation of β-1,4-Oligoglucosides by Certain *Acetobacter* Species

Recent studies[1] in these laboratories have revealed the presence of cellobiose, cellotriose and cellotetraose in cellulose-producing cultures of *Acetobacter acetigenum*, *NCIB* 8132. The present communication deals with an extension of this work in which other cellulose-producing cultures were examined for the presence of β-1,4-oligoglucosides. Mutant organisms unable to produce extracellular cellulose (celluloseless mutants) were also studied.

The cellulose-producing cultures examined were *Acetobacter acetigenum*, *NCIB* 8132, *A. xylinum*, *NCIB* 8034 and *A. xylinum* var. *africanum*, *NCIB* 7029; these cultures were obtained from the National Collection of Industrial Bacteria, Teddington, Middlesex. Cultures of celluloseless mutants were isolated from the wild-type cultures by methods described previously[2]; these are 'natural' mutants which occur spontaneously, that is, without treatment of the parent culture with mutagenic agents. Two mutant cultures were examined from each of organisms *NCIB* 8132 and *NCIB* 8034 and one from organism *NCIB* 7029. The parent and the mutant organisms were grown in a medium (pH 6·0) which contained the following components (per cent, w/v) in distilled water: glucose, 3·0; dibasic potassium phosphate, 0·3; ammonium sulphate, 0·3; magnesium sulphate heptahydrate, 0·2; calcium pantothenate, 0·0002; riboflavin, 0·0002; and biotin, 0·00003. One litre of medium, dispensed at 250 ml./mould culture-flask[3], was inoculated with the desired test organism and after ten days incubation at 28° the contents of the four flasks were pooled and processed as follows. The bacteria were removed by Seitz filtration of the medium, solid barium carbonate (0·5 gm.) was added, the solution was concentrated (*in vacuo*, below 40°) to about 200 ml. and then passed through a charcoal–'Celite' column[4] to separate the oligosaccharides. Elution with water, 7·5 per cent (v/v) ethanol and 20 per cent ethanol (1·5 l. of each), respectively, gave fractions 1–3. A fourth fraction was obtained by boiling the charcoal–'Celite' mixture in 30 per cent ethanol[5]. All fractions were concentrated to about 20 ml. (*in vacuo*, below 40°), deionized with 'Zeo-Karb 225 (H)' and then with 'Amberlite *IR*-4*B* (OH)'. After removal of the resin, the solutions were concentrated to syrups and examined for the presence of oligosaccharides by paper chromatography[6].

A sugar component with an R_F value similar to that of authentic glucose was found in all fractions, thus indicating that a complete separation of the sugars had not been achieved. However, fraction 3 obtained from each parent culture showed a sugar which corresponded in mobility to authentic cellobiose; also, a similar fraction obtained from organisms *NCIB* 8132 and *NCIB* 7029 showed a sugar corresponding in movement on the paper to cellotriose. These findings were supported by chromatography of these sugars as their *N*-benzylamine derivatives[7]. No attempt was made to identify other sugars present. Examination of the five mutant cultures failed to reveal sugars with mobilities similar to authentic cellobiose or cellotriose in any fraction.

The accumulation of cellobiose and cellotriose in cellulose-producing cultures and the absence of detectable amounts of these sugars in cultures of celluloseless mutants strengthens the hypothesis that these sugars are concerned in the synthesis of bacterial cellulose, although it is not a rigid proof of this. If these sugars are in fact intermediate products, then it would appear that the block in the mechanism of cellulose synthesis, in all the mutant cultures examined, occurred at a stage prior to the formation of cellobiose. Cultures of mutant organisms did not produce cellulose when grown in a medium containing cellobiose.

One of us (R. S.) acknowledges the receipt of an Imperial Chemical Industries Research Fellowship.

Phototropism of *Phycomyces* Sporangiophores

In a recent communication, Curry and Gruen[1] reported that sporangiophores of *Phycomyces blakesleeanus* showed strong negative phototropism when exposed to wave-lengths shorter than 300 mμ in addition to the positive phototropism in visible light known to earlier workers. They also showed that this negative response was due to a temporary increase in growth-rate on the side of the sporangiophore nearest the source of light, as they were able to demonstrate a 'light-growth reaction'.

Blaauw[2] demonstrated a 'light-growth reaction' in sporangiophores exposed to visible light, and therefore concluded that positive phototropism must be due to a temporary increase in growth-rate on the far side of the sporangiophore. Castle[3] showed geometrically that the path-length for light was greater in the far half than in the near half of the sporangiophore, owing to a 'lens-effect'. Therefore, provided that the absorption coefficient of the sporangiophore did not exceed a critical value, greater photochemical action could occur in the far half of the sporangiophore than in the near half. Banbury[4] achieved a virtually complete proof of the hypothesis by showing that if one side only of the sporangiophore was illuminated by a grazing beam of light, a temporary increase in growth-rate occurred on that side.

It is therefore clear that radiation of wave-length less than 300 mμ produces a 'light-growth reaction' on the near side and that longer wave-lengths produce a 'light-growth' reaction on the far side. It is suggested that the reason is that at 300 mμ the absorption coefficient of the cell reaches Castle's critical value, and that at shorter wave-lengths the 'lens effect' does not succeed in bringing about greater photochemical activity in the far side of the cell than in the near side. This suggestion is plausible, since a number of the constituents of protoplasm absorb strongly only at wave-lengths less than 300 mμ. A critical test would appear to be the illumination of sporangiophores with light of 302 mμ wave-length, which does not cause any phototropic response, and to find whether a 'light-growth reaction' occurred. A positive result would confirm the theory.

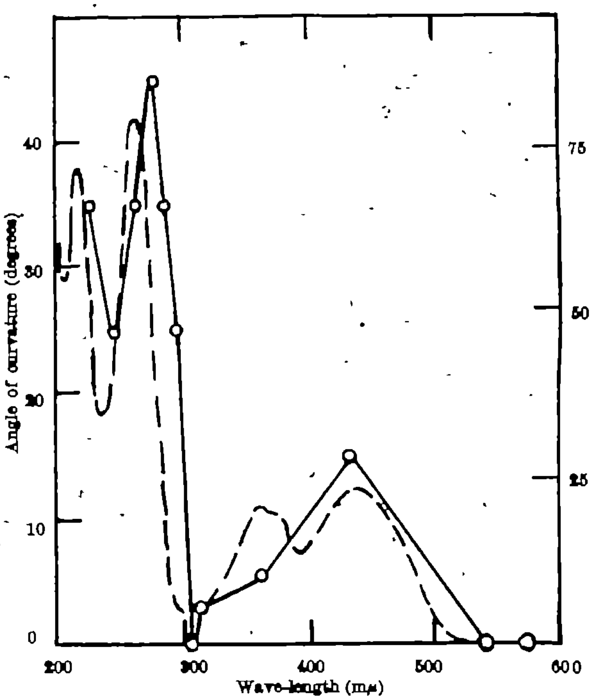

Fig. 1. Action spectrum of phototropic response, —○—. The means of Curry and Gruen's values for angle of curvature of sporangiophore are taken. Absorption spectrum of riboflavin, – – –

Provisionally assuming the correctness of the theory, the results of Curry and Gruen can be plotted as an action spectrum (Fig. 1), the sign of the phototropic response being ignored. It will be seen that the curve agrees closely with the absorption spectrum given for lactoflavin[5], now known to be identical with riboflavin. The major peak of the action spectrum is, however, at 280 mμ while the corresponding riboflavin maximum is at 265 mμ. This would be explicable if the riboflavin is the prosthetic group of a protein, as this, by analogy with flavin adenine dinucleotide[6], would be likely to shift the spectrum about 15 mμ towards the red.

Brauner[7] summarizes the reasons for regarding phototropism as being due to a riboflavin-sensitized destruction of indolyl acetic acid. In higher plants the destruction of indolyl acetic acid leads to reduced growth-rate, whereas in fungi, he suggests, the concentration of indolyl acetic acid is already supra-optimal and its destruction leads to an increased growth-rate. The above discussion shows that the results of Curry and Gruen may be interpreted as showing that both positive and negative phototropism in *Phycomyces* is due to a single riboflavin-mediated response.

I wish to thank Dr. L. E. Hawker and Prof. E. W. Yemm for helpful discussion.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

DEMONSTRATOR (with an honours degree in chemistry or biochemistry, and prepared to engage in research in biochemistry with a view to obtaining a higher degree) IN THE DEPARTMENT OF CHEMISTRY AND BIOCHEMISTRY—The Dean, St. Thomas's Hospital Medical School, London, S.E.1 (August 1).

HOSPITAL PHYSICIST (Senior or Basic grade) IN THE RADIOTHERAPY DEPARTMENT—The Secretary, North Middlesex Hospital, London, N.18 (August 2).

SCIENTIFIC OFFICER (with a good honours degree in science) for genetical and breeding research in field beans and forage crops—The Secretary, Plant Breeding Institute, Trumpington, Cambridge (August 2).

SPECIAL ANALYSIS RESEARCH OFFICER (with a postgraduate degree, preferably Ph.D., from a recognized university, and basic training in geology) IN THE DIVISION OF BUILDING RESEARCH, National Research Council of Canada, to carry out research relating to building materials, involving petrographic, X-ray diffraction and differential thermal analysis methods for the identification of minerals in clays, and concrete aggregates and special chemical constituents of concrete—Chief Scientific Liaison Officer, National Research Council of Canada, Africa House, Kingsway, London, W.C.2 (August 2).

ASSISTANT, Grade B (graduate, with research or industrial experience) IN METALLURGY—The Principal, Derby and District College of Technology, Normanton Road, Derby (August 3).

JOHN STOKES RESEARCH FELLOW to carry out in one of the departments of Sheffield University Medical School or in a teaching hospital associated with the Medical School, original research work in some branch of medical science approved by the Advisory Committee—The Registrar, The University, Sheffield (August 3).

SENIOR LECTURER (with industrial and/or research experience, and capable of initiating and supervising the work of research assistants) to teach electronics and physics to B.Sc. General and Special students—The Registrar, College of Technology, Suffolk Street, Birmingham (August 3).

ASSISTANT LECTURER (with special interests or training in experimental and statistical psychology) IN PSYCHOLOGY—The Registrar, The University, Manchester (August 10).

BOTANICAL ASSISTANT (male) for duties which include the teaching of elementary botany and the identification and labelling of plants—The Director, The Royal Horticultural Society's Gardens, Wisley, Ripley, Woking, Surrey (August 10).

CHEMIST (with a good honours degree, and preferably previous experience of radiochemical and analytical work) to take charge of a laboratory examining radioactive substances in biological materials—The Secretary, Agricultural Research Council, Cunard Building, 15 Regent Street, London, S.W.1 (August 12).

ASSISTANT EXPERIMENTAL OFFICER (with a pass degree or equivalent qualification) IN THE DEPARTMENT OF PHYSIOLOGY AND PLANT CULTURE, to act as personal Research Assistant to the Head of the Department—The Secretary, John Innes Horticultural Institution, Bayfordbury, Hertford (August 14)

MINING CONSULTANT (not under 45 and preferably not over 55, with a wide and varied experience of deep and open-cast mining, and previous experience in a consultative and advisory capacity to important mining concerns) with the Government of Tanganyika, to advise the Government on technical matters relating to the mining industry and to act in a consultative capacity to mining undertakings operating in Tanganyika and requiring professional advice and assistance—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.99/8/02 (August 15).

CHAIR OF ENGINEERING—The Registrar, The University, Southampton (August 17).

DIRECTOR OF THE ELECTRONIC COMPUTATION LABORATORY IN THE DEPARTMENT OF APPLIED MATHEMATICS—The Registrar, The University, Sheffield (August 17).

LECTURER/SENIOR LECTURER (preferably with research experience in supersonics and boundary layer theory) IN AERONAUTICAL ENGINEERING at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 17).

STUDENT IN THE DEPARTMENT OF CHEMISTRY, for research on the pyrolysis of high molecular weight organic compounds and the investigation of the carbons so produced, especially by adsorption techniques—The Registrar, The University, Hull (August 19).

READER IN ELECTRICAL ENGINEERING at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (August 22).

FUEL TECHNOLOGIST or PHYSICAL CHEMIST (with a university honours degree in science, applied science or fuel technology, together with some postgraduate research experience, preferably in coal preparation) IN THE COAL RESEARCH SECTION, Commonwealth Scientific and Industrial Research Organization, North Ryde, Sydney, N.S.W., to initiate research and to undertake investigations in coal washing and preparation, with emphasis on the cleaning of fine coal—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Ref. No. 480/225 (August 24).

RESEARCH ASSISTANT (with research experience (academic or industrial) in polymer science) IN THE DEPARTMENT OF CHEMISTRY, to assist in a programme of work on the synthesis of polyethers and a study of their physical properties—The Registrar, The University, Manchester 13 (August 26)

CHAIR OF BACTERIOLOGY in the University of Cape Town—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, August 31).

LECTURER IN MATHEMATICS, Durban; and a LECTURER IN ZOOLOGY, Pietermaritzburg (University of Natal, South Africa)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, August 31).

LECTURER or SENIOR LECTURER IN FLUID DYNAMICS IN THE DEPARTMENT OF CIVIL ENGINEERING, University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 31).

LECTURERS (2) IN MATHEMATICS at Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, August 31).

PROFESSOR OF MECHANICAL ENGINEERING at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, August 31).

SENIOR LECTURER IN PHYSICAL CHEMISTRY at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, August 31).

STATISTICIAN, SENIOR SCIENTIFIC OFFICER or SCIENTIFIC OFFICER grade (with an honours degree and statistical training or experience); and an ASSISTANT EXPERIMENTAL OFFICER (graduate in botany, horticulture or agriculture with mathematical aptitude, or in mathematics or statistics with biological interests)—The Secretary, East Malling Research Station, near Maidstone, Kent (August 31).

LECTURER IN GEOLOGY at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, September 1).

LECTURER or ASSISTANT LECTURER (with a higher degree in biochemistry or physiology) IN BIOCHEMISTRY—The Secretary and Registrar, The University, Southampton (September 7).

STATISTICIAN (with an honours degree or postgraduate diploma in statistics or equivalent, and a special interest in biometry and design and analysis of experiments)—The Secretary, The University, Aberdeen (September 7).

COWBURN RESEARCH FELLOW (not necessarily medically qualified) to undertake research on blood coagulation in relation to human disease—The Secretary, King's College Hospital Medical School (University of London), Denmark Hill, London, S.E.5 (September 14).

FIELD GEOLOGIST (graduate in geology) with the Geological Survey of Greenland, to undertake field work in the Precambrian of South Greenland—The Director, Geological Survey of Greenland, Grønlands Geologiske Undersøgelse, Østervoldgade 7, Copenhagen K., Denmark (September 15).

SENIOR LECTURER IN CIVIL ENGINEERING; and a LECTURER IN CIVIL ENGINEERING at Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, September 30).

ANALYST (with a science degree with chemistry as one subject, and preferably a knowledge of bacteriology) in the Northern Region of Nigeria, for the chemical and bacteriological analyses of water and foods—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.97/408/03.

ASSISTANT LECTURER IN ORGANIC CHEMISTRY—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8.

CHEMISTRY GRADUATE for research work IN THE CHEMISTRY DEPARTMENT on problems of physical-organic chemistry with particular relation to organo-phosphorus compounds—The Registrar, Queen Mary College, Mile End Road, London, E.1.

EXPERIMENTAL ASSISTANT (with at least G.C.E. including one science subject, and preferably a fondness for outdoor work and ability to drive) IN THE DEPARTMENT OF AGRICULTURAL BOTANY, for responsible field and laboratory work on crops—The Bursar, The University, Reading, Berks.

LABORATORY ASSISTANT (with sufficient experience of school or university work to take charge of the Chemistry Laboratories)—The Bursar, The College, Cheltenham.

LECTURER (graduate in pharmacy and/or Fellow of the Pharmaceutical Society or equivalent qualifications, and preferably industrial, research and teaching experience) IN PHARMACEUTICS, at the City College of Technology, Byrom Street, Liverpool—The Director of Education, 14 Sir Thomas Street, Liverpool.

LECTURER (with academic qualifications and postgraduate experience in physical chemistry) IN THE CHEMISTRY DEPARTMENT—The Clerk to the Governing Body, Battersea College of Technology, London, S.W.11.

RESEARCH FELLOW, and a RESEARCH SCHOLAR IN THE DEPARTMENT OF CHEMISTRY, for work on organo-silicon compounds—The Registrar, The University, Leicester.

RESEARCH FELLOW IN THE DEPARTMENT OF PATHOLOGY, to investigate the serological aspects of neoplasms—The Dean, Guy's Hospital Medical School, London, S.E.1.

SENIOR LECTURER IN ELECTRICAL ENGINEERING at Bradford Institute of Technology—The Director of Education, Town Hall, Bradford.

SENIOR LECTURER IN MINING—The Secretary, Royal College of Science and Technology, Glasgow.

ECONOMICS OF ATOMIC ENERGY

By MARY S. GOLDING, B.A. 15s.

The second book in the 'Atoms for Peace Series' explains, in non-technical language, the impact of nuclear energy on society and discusses critically the effect of this new development on a country's economy; how far a country should want to establish an indigenous atomic industry; what prospects there are for atomic power; and what prospects for international trade in atomic plants and materials, how the industry is organised and administered, and lastly, what Britain's role is and should be in the future of this new industry.

EXCITED STATES IN CHEMISTRY AND BIOLOGY

By C. REID, B.Sc., A.R.C.S., Ph.D., F.C.I.C.,
Professor of Chemistry, University of British Columbia. 45s

In normal biological systems, we know that ionization plays a vital part in all metabolic processes. There is less direct evidence, however, about the part played by excited states in biological reactions, except in the cases where a chain of events is actually initiated by exciting radiation as in the case of the phenomena of vision or photosynthesis. A great deal of indirect evidence, however, suggests that many biological reactions are brought about by a true excited-state mechanism.

Without impinging on the area of "classical" photochemistry, the object of this book is to outline some of the more important physical concepts concerning molecular excitation and interaction, and to apply them to a number of chemical and biochemical situations.

REGIME BEHAVIOUR OF CANALS AND RIVERS

By T. BLENCH, B.Sc., M.I.C.E., M.A.S.C.E.,
Professor of Civil Engineering, University of Alberta. 30s.

The aim of this book is to give the practising engineer the means to solve, with practical quantitative accuracy, problems that arise in dealing with canals and rivers that form their boundaries from sediment, so will not submit to arbitrary interference. It will also form a useful University textbook on mobile hydraulics and its applications to river and canal engineering.

LECTURES AND COURSES

CHELSEA POLYTECHNIC

(COLLEGE OF ADVANCED TECHNOLOGY)
MANRESA ROAD, S.W.3
DEPARTMENT OF CHEMISTRY
Session 1957-58
Head of Department: J. F. J. Dippy, D.Sc., F.R.I.C.

Recognized Day and Evening Courses leading to B.Sc. degrees (London, Internal), and the Graduateship and the Diploma (Food and Drugs) of the Royal Institute of Chemistry, commence on Monday, September 23, 1957. Various post-graduate courses are also available.

Full particulars on application to the Secretary

GLOUCESTER TECHNICAL COLLEGE

A one-year full-time course for Part II of the Graduateship of the Royal Institute of Chemistry, for students who have passed or who hold qualifications which entitle them to exemption from Part I of this examination, will again be held in the session 1957-8.

Further particulars may be obtained from the Principal, to whom applicants should write as soon as possible, giving full details of previous education and experience

OFFICIAL APPOINTMENTS

SOIL MICROBIOLOGIST

Applications are invited for the position of Assistant Professor of Soil Science, prefer duties to commence November or December, 1957 Initial salary $5,000 to $6,200 depending on qualifications, plus a summer supplement of $700; normal yearly increment $300. Graduate with soil science specialization and having Ph.D. degree or equivalent training preferred. Duties include research, teaching and extension work in the field of soil microbiology. Confirmation of appointment subject to satisfactory completion of probationary period of two to four years.

Applications, providing details of training and experience, personal information, a recent photograph and the names of three references, should be addressed to C. F. Bentley, Department of Soil Science, University of Alberta, Edmonton, Canada. Closing date, October 31, 1957.

UNIVERSITY OF THE WITWATERSRAND

JOHANNESBURG, SOUTH AFRICA

Applications are invited for appointment to the post of Professor of Mechanical Engineering who is Head of the Department of Mechanical Engineering. Duties are to be assumed on January 1, 1958, or as soon as possible thereafter. The substantive salary attached to the appointment is on the scale £1,950 by £50 to £2,250 per annum. A married man will also receive a temporary cost of living allowance which is at present at the rate of £234 per annum In addition the substantive salary will be augmented by subvention from outside sources in the form of a non-pensionable allowance which will guarantee an inclusive substantive salary at the rate of £2,500 per annum until the end of 1963. Membership of the Provident Fund is compulsory. Membership of the Staff Medical Aid Fund is compulsory in the case of an officer who is found eligible for such membership.

Applicants are advised to obtain a copy of the information sheet relating to the above vacant post from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close in South Africa and London on August 31, 1957

UNIVERSITY OF QUEENSLAND

AUSTRALIA

Applications are invited for the position of Senior Lecturer (Clinical) in Tropical Medicine The applicants should have a higher qualification in clinical medicine; in addition he should have a higher qualification in tropical medicine or have had special experience in tropical medicine. Previous experience in medical research is desirable but not absolutely essential. Duties will include responsibility for directing the University course in Tropical Medicine and also consultant care of patients, who may or may not be suffering from tropical diseases, in the Wards and Outpatients' Department of the Brisbane Hospital. Salary is £A 2,160/£A 2,460 per annum.

Further particulars are obtainable from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close in Australia and London on September 30, 1957.

SPECIAL ANALYSIS RESEARCH OFFICER

The National Research Council of Canada, has an immediate opening in the Division of Building Research, Ottawa, for a Special Analysis Research Officer to carry out research relating to building materials; this will involve petrographic, X-ray diffraction and differential thermal analysis methods for the identification of minerals in clays, and concrete aggregates and special chemical constituents of concrete. These duties will involve working, with established groups as well as on independent studies. A postgraduate degree, preferably a Ph.D., from a recognized university is required, with basic training in geology. For a man with a Ph.D. and no experience, the starting salary will be $6,000 per annum, with a suitable upward adjustment for relevant experience.

Applicants from within the United Kingdom should apply by mail, giving age, telephone number, and full details of education and experience, to the Chief Scientific Liaison Officer, National Research Council of Canada, Africa House, Kingsway, London, W.C.2, not later than August 2, 1957. All other applicants should apply direct to the Employment Officer, National Research Council, Sussex Drive, Ottawa, 2, Canada.

VIBRATION RESEARCH

The National Research Council of Canada, Ottawa, has an immediate vacancy for a Research Officer in the Division of Building Research. Duties will include basic research in ground vibrations, their propagation and their effect on building structures; dealing with construction problems relating to ground vibrations; studying effects on building structures of earthquakes, blasting, pile-driving, etc., and developing suitable instruments for the above studies. Minimum qualifications required, Bachelor's degree in physics or engineering physics plus several years' experience in theory of wave propagation, seismology and acoustics. The starting salary will be a minimum of $4,600 per annum with a suitable upward adjustment for further education or relevant experience.

Applicants from within the United Kingdom should apply by mail, giving age, telephone number, and full details of education and experience, to the Chief Scientific Liaison Officer, National Research Council of Canada, Africa House, Kingsway, London, W.C.2, by not later than August 2, 1957. All other applicants should apply direct to the Employment Officer, National Research Council, Sussex Drive, Ottawa, 2 Canada.

UNIVERSITY OF MANCHESTER

Applications are invited for a post in the Department of Physics at one of the following grades: Senior Lecturer or Assistant Lecturer. The salary scales are as follows: Senior Lecturer, £1,700 to £2,050 per annum; Lecturer, £900 to £1,650 per annum; Assistant Lecturer, £700 to £850 per annum Initial salary and status according to qualifications and experience. Membership of F.S.S.U. and children's allowance scheme.

Applications should be sent not later than August 12, 1957, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained.

UNIVERSITY COLLEGE OF SWANSEA

Applications are invited for the post of Assistant Lecturer or Lecturer in Electrical Engineering. Salary: Assistant Lectureship in the range £700 to £850 per annum; initial salary according to age and qualifications. Lectureship, £900 to £1,650 per annum (only in an exceptional case will the initial salary be more than £1,100) F.S.S.U. benefits and family allowances.

Further particulars may be obtained from the Registrar, University College, Singleton Park, Swansea, to whom applications must be sent by August 17, 1957.

KING'S COLLEGE HOSPITAL MEDICAL School (University of London), Denmark Hill, S.E.5. Applications are invited for the Cowburn Research Fellowship tenable in the Medical School The successful applicant, who need not be medically qualified, will be expected to undertake research on blood coagulation in relation to human disease. The Fellowship will be full time, tenable for up to three years. The stipend will be £1,200 a year plus F.S.S.U.—Further particulars may be obtained from the Secretary of the Medical School, to whom applications, giving full particulars of age, qualifications and experience, together with the names of three referees, should be sent before Saturday, September 14, 1957.

MIDDLESEX COUNTY COUNCIL —EDUCATION COMMITTEE

Applications are invited for following vacancies:

(I) BRUNEL COLLEGE OF TECHNOLOGY

WORKSHOP TECHNICIANS (Misc IV and V). Electronics division Considerable experience essential in industrial electronics, test gear radio and television construction.

LABORATORY STEWARD (Misc. IV) and Laboratory Assistants (Misc. III). General laboratory duties. Experience in X-ray diffraction desirable.

(II) ACTON TECHNICAL COLLEGE

LABORATORY STEWARD (Misc. IV). General duties in Physics laboratory up to G.C.E. Advanced Level. Previous experience required.

Salaries, Misc. V, £574 to £635 10s. Misc. IV, £502 5s. to £589 7s. 6d. Misc. III, £456 2s 6d. to £522 15s. (London weighting up to £30 per annum payable in addition). All posts 38-hour week. Prescribed conditions.

Apply, stating age, qualifications and experience to Principal, Acton Technical College, High Street, Acton, W.3, by August 10 (quote V 607 N). Canvassing disqualifies.

UNIVERSITY OF WESTERN AUSTRALIA

Applications are invited for the post of Senior Lecturer in Mechanical Engineering. Applicants should hold an honours degree or higher degree in mechanical engineering. The salary range is £A.1,850 to £A2,150 per annum plus cost of living allowance (at present £A.43 per annum). The commencing salary will be determined on the basis of the qualifications and experience of the appointee. An allowance is made towards travel and removal expenses and housing assistance is available.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C 1. The closing date for the receipt of applications, in Australia, and in London, is September 28, 1957.

CENTRAL ELECTRICITY AUTHORITY

RESEARCH LABORATORIES

LEATHERHEAD, Surrey, require ENGINEERS in the Generation Section. Investigations cover a wide range of problems associated with conventional and nuclear power stations, including heat transfer in nuclear fuel elements and heat exchangers, electrostatic precipitators and cooling towers. Ability to apply fundamental knowledge to a wide range of problems important. Candidates for 2nd and 3rd Assistant vacancies should, preferably, have an honours degree with previous experience. For other posts a pass degree or H.N.C is acceptable.

2nd Assistant Engineer,	£1,160	to	£1,510	p a.
3rd Assistant Engineer,	£1,055	to	£1,265	p a.
4th Assistant Engineer,	£820	to	£995	p.a.
General Assistant Engineer	£550	to	£725	p a

according to qualifications and experience.

Applications, stating age, qualifications, experience, present position and salary, to D. Moffat, Director of Establishments, Winsley Street, London, W.1, by August 6. Quote ref. N/315.

D.S.I.R. REQUIRES SCIENTIFIC OFFICERS at Building Research Station, Garston, Herts, as follows: (1) For research in laboratory and field on soil mechanics problems (ref. E.444/7A). Candidates should have some practical experience on civil engineering work or basic knowledge of soil mechanics. (2) Civil Engineer (ref. E.445/7A) with a good knowledge of materials and structures. (3) Inorganic or Physical Chemist (ref. F.356/7A) for investigation of durability of ferrous and non-ferrous metals used in building and study of effects produced by their contact with other building materials. (4) Physical Chemist or Physicist (ref. F 357/7A) to study flow properties of suspensions in relation to consistence and workability of building materials. (5) Inorganic or Physical Chemist (ref. F.358/7A). (6) Physicist (ref. A.202/7A) for research in heating and ventilation. Qualifications: First- or second-class honours degree or equivalent in engineering for posts (1) and (2), and in chemistry or physics as appropriate for remainder. Salary range £565 to £995 (men), lower maximum for women, but equal pay scheme. Five-day week.—Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting appropriate reference. Closing date August 10, 1957.

Do you need

one copy—or several?

Every organisation has its own particular document-copying requirements, so you alone can decide which copying method would be most suitable for your purposes.

For example, is time a very important factor? Would you require one copy of a document, or several? Would originals be single-sided or double-sided? Who would use the equipment? Would copies have to be despatched immediately? These and other factors must influence your choice.

So before you start buying, get in touch with Kodak, who have an immense amount of document-copying experience behind them. They will provide you with a great deal of information that should help you to select the most suitable method for your particular needs.

DIRECT READING pH METER

MODEL 23A

This high-grade laboratory pH Meter is one of the most widely used instruments in electrochemical research.

Some 50 different types of electrodes are available for pH, redox and micro analytical work. Stable to 0.02 pH with a B.S. precision grade meter and a recorder output.

TRAINING OF MEDICAL STUDENTS

THE General Medical Council is charged by Act of Parliament with the supervision of medical education in Britain, and is empowered to appoint visitors and inspectors to report on the quality and content of the training afforded by medical schools, and on the quality and standard of the examinations which punctuate the medical student's career. A number of "Recommendations as to the Medical Curriculum" were published by the Council in 1947, and were referred to at the time in a leading article in *Nature* (160, 482; 1947). Two main criticisms which these recommendations have evoked over the past ten years is that they were too detailed and precise, and that they left insufficient scope to licensing bodies and schools to vary their curricula and requirements as experience dictated. The biggest stumbling-block to independent action was that the whole period of professional study—five academic years—was divided into a period of pre-clinical studies, a transitional period of studies leading to the clinical course, and a period of clinical studies, for each of which a minimum duration was recommended. A new set of recommendations has now been issued, very much shorter than the last, which departs from these temporal stipulations. While the Council insists, as before, on a minimum of five academic years for the full course, it does not lay down how the time which the medical student has to devote to all his professional studies should be subdivided between various subjects. This is now left to the initiative of licensing bodies and schools. Similarly, the new recommendations do not lay down, as a requirement, the number of separate subjects in which medical students should be examined, leaving it again to the authorities in each medical school, and to the licensing bodies, to decide whether or not certain of them can be combined in a single examination.

There are a number of other differences between the older recommendations and the new and shorter set by which they are superseded. One of the most interesting is that the Council has revoked a recommendation which has prevailed hitherto, and which no doubt reflected a practice that was centuries old, that each medical student should dissect the whole body during the period of his anatomical studies.

For the rest, the recommendations are in the same general terms as before. The Council continues to emphasize the need to reduce the congestion of the curriculum. But only the individual teacher can reveal what value there is in admonitions to eliminate unnecessary detail and specialization from the curriculum; in exhortations to integrate its various sections; in counsel that it is better to educate than to instruct; or in a generalization that the critical study of principles develops a capacity for independent thought far better than does an insistence on the memorization of factual data. Judging by previous results, the average teacher of medicine is somewhat allergic to these pieces of advice.

THE LONDON SCHOOL OF TROPICAL MEDICINE

History of the School of Tropical Medicine in London (1899–1949)
By Sir Philip Manson-Bahr. (London School of Hygiene and Tropical Medicine Memoir No. 11.) Pp. xiv+329. (London: H. K. Lewis and Co., Ltd., 1956.) 50*s*. net.

THE appearance of a new volume in the series of memoirs from the London School of Hygiene and Tropical Medicine is an important event in the literature of tropical medicine. This historical record of the London School from its foundation until 1949 maintains the high standards set by the preceding volumes. It is particularly valuable in that it is written by one who joined the staff of the School in 1909 and remained with it until he retired from the post of director of the Clinical Division in 1947. He therefore knew intimately the great figures who created and built up the School over its first fifty years, and he was personally implicated in the development of its clinical side.

The book is divided into four sections. The first, the historical section, begins by sketching the situation in regard to tropical medicine in the last decade of the nineteenth century. Sir Patrick Manson had returned from the Far East in 1893 and was practising in London, and in 1897 he was appointed medical adviser to the Colonial Office. The Prime Minister was so impressed by his description of the backward state of knowledge of tropical diseases that in 1898 he addressed a circular letter to the relevant authorities in Great Britain suggesting that facilities should be provided for training future medical officers of the Colonies in this subject. Preparations were immediately made for creating Schools of Tropical Medicine in Liverpool and London, and these were opened to students in 1899, the London School in the hospital of the Seamen's Hospital Society at Greenwich. The expansion and development of the London School and its contributions to the advancement of knowledge are then described. The buildings at Greenwich became too small, and in 1919 the School moved to Endsleigh Gardens, where again the accommodation soon became inadequate. In 1926 the Rockefeller Foundation offered a gift of two million dollars to the proposed new School of Hygiene in London on condition that it incorporated the London School of Tropical Medicine. This offer was accepted, and in 1929 the School of Tropical Medicine was integrated with the School of Hygiene in its present buildings. Further chapters are concerned with such subjects as the library, the museum, and the important malaria experiment in 1900 in the Roman Campagna which demonstrated that malaria could be prevented by protecting man from the bites of mosquitoes.

The author then gives a series of short biographies of members of the staff and workers at the School since its formation. Each presents briefly, in addition to a catalogue of scientific attainment, an intimate picture of its subject enlivened by the author's personal memories. They include not merely those whose names are famous, but also all who taught and helped in research, including assistant staff. The only biography missing is that of the author himself, and that has been contributed in a preface by Dr. Charles Wilcocks. A detailed diary follows, which records in chronological order all the important events in the history of the School, and the book concludes with an appendix giving accounts of the School's research expeditions, a note on the collected papers of the staff, lists of prize-winners, a copy of the syllabus adopted in 1925, and a résumé of the clinical work of the School during 1920–39.

This volume will prove of great interest to all who are concerned with tropical medicine because it is a history of the development of a large part of our knowledge of tropical disease. Past students will recapture in its pages the atmosphere they knew. It is written in a highly readable manner with many amusing anecdotes and is magnificently produced with numerous photographs of persons and places.

T. H. DAVEY

FREQUENCY MODULATION IN RADIO

Frequency Modulation

By L. B. Arguimbau and R. D. Stuart. (Methuen's Monographs on Physical Subjects.) Pp. vii+96. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1956.) 8s. 6d.

Frequency Modulation Engineering

By Christopher E. Tibbs and G. G. Johnstone. Second edition, revised. Pp. xii+435. (London: Chapman and Hall, Ltd., 1956.) 45s. net.

IN the frequency modulation system of radio signalling, the frequency of the carrier waves is varied while the amplitude is maintained constant. The theoretical principles of frequency-modulated waves and the resulting spectrum of the radiation have been known for well over a quarter of a century; and the possibilities of an improved signal-to-noise ratio from the system were demonstrated at least twenty years ago. But during this period much controversy has taken place over the relative merits of frequency and amplitude modulation, particularly for broadcasting purposes. The introduction of very high frequencies into practical transmission has greatly increased interest in this subject.

The monograph by Messrs. Arguimbau and Stuart forms a useful introduction to the frequency modulation system as a means of reducing the effect of extraneous disturbances during radio transmission. After a theoretical chapter on the nature of frequency modulation, the principles and circuit arrangements of suitable transmitters and receivers are dealt with. Then follows an important chapter on interference and the means of reducing this; and a brief consideration of the application of the system to television concludes the book. The addition of a few references at the end of each chapter helps to make this monograph a useful introduction to the whole subject.

The larger work by Messrs. Tibbs and Johnstone constitutes a major revision and expansion of an earlier edition of the book by the first author; and it is intended to provide a concise survey of the application of frequency modulation to radio engineering. As stated in a foreword by Dr. K. R. Sturley, head of the B.B.C. Engineering Training Department, the exploitation of frequency modulation for broadcasting was delayed in Britain by the War; but with the Government's decision, in July 1954, to inaugurate a very high frequency sound broadcasting service, much greater interest was aroused in the subject.

After introductory chapters on the principles of frequency modulation, the structure of electrical noise and its suppression as a source of interference in radio reception are considered in detail. Furthermore, since the modern application of frequency modulation is to carrier wave frequencies greater than 30 Mc./s. (wave-lengths less than 10 metres), the authors justifiably devote separate chapters to the propagation of very short waves, and to the aerial systems with which they are used. These chapters are important in enabling the engineer to understand how distortion of the audiofrequency signals can arise due to wave reflexion effects; they also direct his attention to the care necessary in the design of receivers. The second half of the book deals with the principles and practical design of transmitters, receivers and measuring instruments for frequency modulation systems, with a brief indication of their application to services other than broadcasting. The selected references at the end of each chapter appear to indicate that most of the important literature on the subject of frequency modulation is to be found in American journals.

The publication of this book will therefore help to redress the balance; its production is a credit to both authors and publishers, and it will form a timely and most useful guide to those interested in any of the several engineering aspects of the subject.

R. L. SMITH-ROSE

RECENT ADVANCES IN SCIENCE

Recent Advances in Science

Physics and Applied Mathematics. Edited by Prof. Morris H. Shamos and Prof. George M. Murphy. Pp. xii+384. (New York: New York University Press and Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1956.) 7.50 dollars.

THE contributions to this excellent survey were originally given as lectures at a symposium arranged in 1954 by the Division of General Education of New York University, where a number of the leading physicists in the United States explained the recent advances in their own fields to a non-specialist gathering of scientific workers. The articles, which deal with work that was in progress at the time and ideas which were then developing, as well as with achievements already accepted, are pretty well up to date with things at present. Thus, H. A. Bethe mentions the plans then being made by Reines and Cowan to detect the neutrino by inverse beta-decay; C. H. Townes explains the principle of the 'maser' (as yet unnamed), being rather guarded as to whether it will eventually work usefully; and L. J. Haworth, looking forward into the next decade, completes a discussion of the alternating-gradient synchrotron with a picture of the Brookhaven machine when happily settled on its estate.

There is a well-illustrated account by N. F. Ramsey of experimental work on neutron physics; W. Shockley gives a fairly elementary but full description of transistor physics; and R. M. Bozorth on ferromagnetism mentions many interesting recent applications of the ferrites and other new materials. On the more theoretical side, I. I. Rabi discusses atomic structure, emphasizing the importance of recent work on positronium; and F. G. Brickwedde explains the curious physical and statistical properties of the quantum liquid, helium II. V. F. Weiskopf analyses the complicated pattern of the elementary particles, and forecasts more to come as cosmotron work in the ultra-high energy range develops. There are three contributions of a more general type—Richard Courant on the many applications of numerical methods, with the strong-focusing synchrotron, weather forecasting, and flood control as typical examples; P. M. Morse on the adaptation of operational research to linear programming in business, and the uses of the Monte Carlo method; and E. U. Condon, on physics and the engineer, directing attention to the shortage of high-school science teachers. This last appears to be a feature of the times, and not restricted to any one country; one wonders if it is really the only problem that is quite unapproachable by the methods of operational research, for there must be some way of averting the impending academic dust-bowl.

Each article starts with a brief elementary introduction, and the general reader might gain from the book a good idea of what physicists have been doing recently, more particularly in the United States. But it is primarily intended for the scientific reader who wishes for a broad and fairly detailed picture of current progress. He will find it outstandingly useful.

G. R. NOAKES

THERMODYNAMICS OF BIOLOGICAL SYNTHESIS

Some Principles of Energetics in Biochemical Reactions

By Prof. Irving M. Klotz. Pp. vii+64. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1957.) 3 dollars.

SEVERAL selected topics of thermodynamics are of importance for the interpretation of the results of biochemical experiments. A closer understanding of their principles is helpful to biochemists for such practical purposes as well as for a strategic view of problems of the maintenance and development of biological systems. Only 20–25 years ago there were still lively disputes among eminent scientists as to whether the laws of thermodynamics are strictly applicable to biological systems. Some suggested that evolution or man's intellect had special 'Maxwell demons' to enable them to contravene the second law of thermodynamics. Good expositions of the thermodynamics of open systems and of the relations between information (intellect) and entropy have converted most people to the only acceptable contention that the laws of thermodynamics are applicable to biological phenomena.

Classical chemical thermodynamics was developed in a form most suitable for the interpretation of the results of experiments of isolated chemical systems at equilibrium and under standard conditions. Biochemical reactions in a cell, or in one of the many multi-enzyme systems used for the study of synthetic processes, are not in equilibrium but in a steady state. The composition of the solution must be suitable for the reaction, and cannot be varied to suit the convenience of physical interpretation. Thermodynamic properties of substances of biochemical importance can, of course, be determined under standard equilibrium conditions, but a study of the special aspects of the energetics of biochemical reactions requires the consideration of special conditions.

In Dr. Klotz's little book none of these problems of importance to biochemists is considered. He presents the most elementary exposition of thermodynamics I have ever seen, and illustrates it with examples from reactions of protein molecules and of biochemically important esters. As such this book should be very useful for students taking a first-year course in a biological subject; no previous knowledge of physics or physical chemistry is required, but the relevance of phosphate transfer should be understood. Even for such a junior reader the first few pages are somewhat unsophisticated, and it is my experience that somewhat greater rigour in the derivation of thermodynamic functions makes it easier for students to understand and remember them.

Apart from the subject-matter mentioned above, Dr. Klotz gives a good elementary account of the thermodynamic principles of electrode processes, osmotic pressure, sedimentation equilibria and of the molecular-statistical basis of thermodynamics. One must not look to this book for thermodynamic data for the reactions discussed; those given are not carefully chosen nor are adequate references to the literature given. Another very serious omission is that nowhere in the book can one find a discussion of the effect of *p*H on the reactions of charged compounds. Ionizable groups are involved either directly or indirectly in most biochemical reactions and consequently a brief treatment of the relation between dissociation constants, hydrogen ion concentration and chemical equilibria does seem essential. One must point out that the so-called standard free energies quoted for various hydrolysis reactions are only valid at definite *p*H values, which are not quoted in the book.

All these remarks should not be taken as a severe criticism of the book; different readers would expect different topics discussed in sixty-four pages under this title. Unfortunately, most people in Britain will find the price prohibitive at about 4*d*. a small page; surely this is just the sort of book which should be available cheaply between paper covers.

HERBERT GUTFREUND

DAIRY PLANT CONTROL

Laboratory Control of Dairy Plant

By Dr. J. G. Davis. Pp. xii+395. (London: Dairy Industries, Ltd., 1956.) 30*s*.

LABORATORY control of dairy plant is becoming more essential nowadays with the ever-increasing tendency for larger 'through-puts' of plant. Mistakes which with small plant were unfortunate can now mean a serious economic loss with large plant. Hence strict laboratory control has now become a necessity, and, in consequence, so has a book on the subject.

The author first deals with the purpose of plant control, and underlines the fact that testing must be economic. The principles of cleaning and sterilizing plant are given a chapter as complementary information to the succeeding chapter on methods of assessing the cleanliness and sterility of dairy plant. On p. 19 the author recommends the inclusion of sodium sulphite in a detergent to minimize attack on tin plant. It might have been helpful if he had pointed out that this should not be included in any detergent for use with sodium hypochlorite. The author, besides giving detailed bacteriological methods, describes simple tests which can sometimes be as useful.

The section on plant control, which is, of course, fundamental to a book such as this, contains details of the operation of conventional pasteurizing and sterilizing plant as well as of later developments such as in-bottle pasteurization and ultra-high temperature heaters. Other types of plant, homogenizers, clarifiers, filters, coolers for milk and also plant for other dairy products, ice cream, evaporated and condensed milk, are also considered, together with the setting and checking of instruments.

Bottles and bottle washers, detergents, sterilants, water and effluents all have separate chapters, in logical sequence. Routine bacteriological, chemical and physical tests dealing with all these aspects are detailed, but all are related in such a manner that it is clear in what circumstances they should be used and how the results of the tests should be interpreted.

Refrigeration and steam raising, and the resultant problem of corrosion are each given chapters, although these can probably be considered as no more than introductions to the subjects. There is a collection of most useful information on volume and weight measurement, trace metal problems, miscellaneous materials and processes, and the book concludes with two chapters on economic and legal aspects, points about which the manager, plant operator and laboratory worker must nowadays have more than passing knowledge.

The text is liberally illustrated with photographs and diagrams; there is an abundance of references in the text, with, in addition, an alphabetical list of references covering eighteen pages.

The author is well qualified to write such a book as this, having worked at a research institute and also in commerce. The book is obviously written as much for the manager as the laboratory staff, and the fundamentals could apply to other food industries. Indeed, this handbook serves a most useful function, is pleasingly got up, and contains very few textual errors.

L. F. L. Clegg

BASES OF INDUCTION

Foundations of Inductive Logic

By Roy Harrod. Pp. xviii+290. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1956.) 24*s*. net.

In the preface to his book, Mr. Harrod modestly describes how, as an eminent economist and biographer, he came to be interested in the problems of induction, and how eventually he came to believe that he had a contribution to offer to their solution. The outcome is the present book, which attempts to place inductive logic on as firm a basis as deductive logic, without the use of such principles as the 'uniformity of Nature' or the 'law of universal causation'; and without reference to prior probabilities. The philosophical outlook is that of Hume but without that author's sceptical conclusions.

The introduction is a brief résumé of the problem. The detailed study begins in Chapter 2 with a definition, based on frequency ideas, of probability. Simple induction is considered in the next chapter and a most ingenious argument is introduced to explain the principle of learning by experience: that what has happened in the past will often continue to happen in the future. In essence the argument is that if one is moving through a continuum then one is unlikely to be near the edge of it. A probability can then be assigned to the event that the continuum will continue for at least a proportion $1/x$ of the time that has already been experienced in it. If the derivation contains a hidden use of prior probabilities, then it has been well disguised. Chapter 4 deals with more general induction problems and contains another involved, but highly interesting, discussion of how a probability can be attached to a hypothesis, without any use of prior probabilities. The Heracleitean hypothesis is considered in the next chapter. Chapter 6 discusses the simplicity postulate introduced by Sir Harold Jeffreys and contains a justification for it. The definition of knowledge, memory, the argument for the existence of other sentient beings, are the topics of the next three chapters. The fundamental principles of induction are reconsidered in Chapter 10 in the light of these discussions, and the book concludes with some remarks on the thoughts it is sensible to have about a world lying beyond that to which our senses give us access.

It might have been thought that the author's central problem was one that needed considerable use of mathematical techniques in its treatment. In the preface (p. vi) there is an apologia for the lack of mathematical expression in the argument, but this is directed more towards mathematical logicians than to those mathematicians, usually termed statisticians, who have developed techniques of inductive logic that are in daily use in scientific thinking. Now Mr. Harrod is concerned with philosophical aspects of the problem, and not with its details of application, and has been most successful in putting forward a thesis with no mathematical language. But he has no excuse for ignoring the philosophical aspects of the statisticians' arguments. In fact, only one statistician, Sir Harold Jeffreys, is mentioned throughout the book. The argument used in Chapter 4, and termed 'reversing the consequents', appears to be a special case of the argument of 'confidence intervals' introduced by Neyman. It is true that the notion of a 'deflator' has not received formal mathematical expression by Neyman, but any statistician would be cognizant of the need for it in an application of the method. There are several strong reasons for disliking confidence intervals, and these have not been mentioned in the book. Again, following similar work by von Neumann and Morgenstern in connexion with the concept of utility in economics, Savage has shown that, subject to some mild requirements, any person acting rationally (that is, satisfying these requirements) is in possession of a prior probability. The central problem of probability theory to-day is not how to do away with the prior probability, but to find what prior probability it is that corresponds to the concept of nescience, if this concept has meaning. It may be that Mr. Harrod has, particularly in Chapter 3, produced an argument which might well be capable of answering this last question, though he places the emphasis differently. The book can be warmly recommended to statisticians, but philosophers should beware of the omission of relevant arguments.

D. V. Lindley

Experimental Physical Chemistry

By Prof. Farrington Daniels, Prof. Joseph Howard Mathews, Prof. John Warren Williams, Prof. Paul Bender and Prof. Robert A. Alberty. Fifth edition. Pp. xi+482. (London: McGraw-Hill Publishing Company, Ltd., 1956.) 49s.

THE avowed object of this book is the same as that of the 1929 and later editions, namely, "to illustrate the principles of physical chemistry, to train in careful experimentation, to develop familiarity with apparatus, to encourage ability in research". The volume is representative of the teaching of the laboratory course at the University of Wisconsin. Part I contains fifty-nine sections each of which describes an experiment and consists of a short introduction, an account of theory, apparatus, procedure, calculations, practical applications, suggestions for further work and references. It is intended that the experiments should be carried out under the guidance of an instructor. The second part of the volume, occupying pp. 321–469, describes apparatus and techniques, particularly for more advanced work. No claim is made for completeness, and the authors have been guided by their own experiences. This part of the book is not very satisfactory because so many subjects are dismissed in so few words. Thus microscopy is discussed in thirty-two lines and spectroscopy (visible, ultra-violet and infra-red) is described in forty-six lines. However, there are some interesting sections such as that dealing with the use of electronics in physical chemistry (twenty-nine pages). The inside of the front cover gives a list of atomic weights while the back cover carries a table of four-figure logarithms. The first part of this book presents the results of considerable experience in the teaching of practical physical chemistry and staffs of universities may well find here useful suggestions for their practical courses. E. F. G. HERINGTON

Acridines

By R. M. Acheson. With a chapter by L. E. Orgel. (Chemistry of Heterocyclic Compounds: a Series of Monographs, Vol. 9.) Pp. xii+409. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1956.) 12.50 dollars.

HETEROCYCLIC chemistry is poorly provided with comprehensive monographs, and this series is designed to provide a detailed treatment of the whole field. This book maintains the high standard set by its predecessors. The anti-malarial and anti-bacterial properties of certain acridines led to an intensive, but somewhat unbalanced, development of acridine chemistry. In Albert's "Acridines", published in 1951, the pharmaceutical aspects are stressed, and the large amount of experimental technique included makes it an invaluable book for the specialist. Acheson, dealing inevitably with much the same information, has adopted a different approach. He has arranged the material in a more logical way; he has emphasized topics of general chemical interest, for example, the mechanism of reactions, and relegated details of individual compounds to a series of extensive and excellent tables. Thus, the book provides lively reading for those interested in heterocyclic chemistry, and also serves as a standard reference text—a rare combination of virtues. Acheson has included an excellent chapter on the acridine alkaloids. This work has its own intrinsic interest, but also illustrates how intensive work on individual compounds illuminates the chemistry of a whole class, in this case the polymethoxy and polyhydroxy acridines. The concise account of the absorption spectra of acridines is well written by Orgel. Some infra-red spectra are reproduced, unfortunately without comment. The text is almost completely free from trivial errors, but the index is not always adequate. M. F. GRUNDON

Dictionary of Microbiology

By Morris B. Jacobs, Maurice J. Gerstein and Prof. William G. Walter. Pp. iv+276. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1957.) 50s. net.

ACCORDING to the publishers' note, this dictionary contains some 5,000 entries giving "clear and explicit definitions of terms from the entire field of microbiology". The entries include systematic names and classification data for bacteria (Bergey's nomenclature), moulds, protozoa and viruses together with antibiotics, etc. Spot tests showed that entries were comprehensive and satisfactory in these fields but less good in other subjects normally included in modern microbiology. For example, there is no reference to eclipse phase, latent phase, lysogency, induction, kinetoplast, chemostat, auxotrophe, lecithinase, strepogenin or racemase. Biochemists will find definitions of some chemical terms somewhat superficial: the various amino-acids are listed and described as "involved in the metabolism of micro-organisms", while pyridoxin derivatives are "probably converted to amino-acid decarboxylases". Transforming Principle is referred to pneumococcal-type transformation only; plasmagenes are "genetic determinants in the broadest sense"; an auxanogram refers to study of inhibitors, while an auxanograph refers to utilization of carbohydrate or nitrogen-bearing substances. In general, the dictionary contains much of use to all microbiologists, but is not of great assistance to the expert who requires precise definition of technical terms or elucidation of recent or uncommon words in his own field.

E. F. GALE

A Scientific Sampler

Edited by Raymond Stevens, Howard F. Hamacher and Alan A. Smith. Pp. xviii+413. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1956.) 45s. net.

ARTHUR D. LITTLE, Inc., is a research organization in the United States with a large staff devoted mainly to research in the applied sciences. Once a month the organization publishes an *Industrial Bulletin* in which the staff are given opportunities for describing their professional and extra-curricular interests in a form suitable for the lay reader. Over the past thirty years a wide range of topics has been considered, and the editors of the *Bulletin* have now brought a large number of them together to form a fascinating book. Some of the articles are more than twenty years old, but have been brought up to date by the addition of suitable footnotes. The variety of subjects covered is so great that it would need exhaustive treatment to cover them; few aspects of science are unrepresented.

"The Scientific Sampler" is a book for which many specialists have been looking. The articles are brief, clearly written and could be used either for reference or as a bedside book. The editors should be congratulated, not only for their choice in authors, but also for the way they have put the book together.

T. H. HAWKINS

THE RESEARCH INSTITUTE (ANIMAL VIRUS DISEASES)

OPEN DAYS

By Dr. IAN A. GALLOWAY
Director

An extensive building and development scheme costing something of the order of £1 million has recently been completed at the Research Institute (Animal Virus Diseases) at Pirbright in Surrey. The Institute is engaged on fundamental research on foot-and-mouth disease and the virus which causes it with the object of discovering methods of control and eradication in Britain and overseas. Investigations are also in progress on certain other viruses, for example, vesicular stomatitis and vesicular exanthema, which cause diseases clinically similar to foot-and-mouth disease. All the work is proving of great interest to workers in the wider field of research on human, animal and plant virus infections.

There was an alteration in the administrative arrangements in 1951 when a governing body was constituted. The members are appointed by the Ministry of Agriculture and the Secretary of State for Scotland after consultation with the Agricultural Research Council and the Medical Research Council. In 1956, responsibility for the grant-aiding functions were transferred from the Ministry of Agriculture to the Agricultural Research Council. The staff now numbers about 150, including twenty scientific officers, thirty laboratory technicians, forty laboratory and animal attendants and thirty engineering and maintenance staff. The annual grant is at present about £200,000. Dr. J. B. Brooksby, who has been a member of the staff of the Institute since 1940, was appointed deputy director in January 1957.

Unfortunately, it was not possible to hold an official opening ceremony and to arrange for a large number of visitors to tour the laboratories on account of the disease security restrictions imposed on staff and visitors. As an alternative, a series of open days was held during June 18–20, to which representatives from several different spheres were invited.

On the first day, Lord Rothschild, chairman of the Agricultural Research Council, replied to a speech of welcome by Mr. Stephen Cheveley, chairman of the governing body. Lord Rothschild emphasized the high reputation of the Institute at home and overseas. He outlined some general principles which should be borne in mind in the fiercely competitive world of science and virology in particular. One of these related to specialization, which, like diversification, could be overdone. He stressed the importance of animal virology and suggested the desirability of pursuing work in this field with greater intensity and of giving thought to the possibility of diversification in the activities of the Pirbright Institute. In this connexion it is noteworthy that the terms of reference of the Institute allow it to undertake research on any viruses and the diseases they produce.

Demonstrations were arranged by the different departments and brief reference may be made to a selection of items of particular interest which were shown and discussed.

Extensive world epidemiological surveys have been carried out by the Institute since 1948, involving the systematic examination and immunological classification of samples of virus. In addition to samples from outbreaks of foot-and-mouth disease in Great Britain, others from Africa, Asia, Central and South America have been examined. There are now seven recognized main immunological types of the virus (compared with three in poliomyelitis, three in influenza, three in equine encephalomyelitis and two in vesicular stomatitis). The well-known *O*, *A* and *C* types (1922–26) have been found in Europe, South America, Asia and Africa. Work at Pirbright has brought to light three other types, designated *S.A.T.*1, *S.A.T.*2 and *S.A.T.*3, in Africa, and recently in 1955 a further type, *ASIA* 1, in five Asian countries. It has been found also that there are, as in influenza, within each of the main immunological type groups, strains of virus which differ sufficiently in antigenic constitution to classify them as variants or sub-types. All these findings are now realized to be of such international importance especially in relation to control measures, which in endemic areas would involve appropriate vaccination, that proposals for recognition of the Institute as the world reference centre for foot-and-mouth disease are under very urgent consideration.

Since the virus of foot-and-mouth disease exhibits a high degree of variability in this multiplicity of types and sub-types as well as in many other properties such as virulence for particular host species, spreading power and invasiveness, work has begun on the genetic analysis of the various factors affecting host–virus relationship. At the same time, studies are being made of methods of inducing variants in the laboratory. The methods employed, which include isolation of pure-line strains by the monolayer tissue culture 'plaque' technique and ultra-violet irradiation, were demonstrated. The necessity of making parallel genetic studies of variation in susceptibility of the host or host cell is appreciated, and already the results of the comparison of the susceptibility of two strains of mice to infection with the virus has demonstrated the influence of the host factor.

The Institute has been responsible for introducing many new methods and techniques which were demonstrated. All of these not only speed up diagnosis and type determination and the production and testing of vaccines, but also lead to greater accuracy in many tests, and economy in the use of the large and expensive experimental animals. They provide a wide range of opportunities for methodological selection and combination for specific objectives and for correlation of experimental data.

These techniques include four methods of virus titration. The first, reported in 1949, is multiple intradermal inoculation at different sites on the tongues of cattle of different dilutions of virus and determination of the 50 per cent end-point infecting dose. The second involves the inoculation intraperitoneally of different dilutions of virus into separate groups of unweaned mice. This followed the demonstration at Pirbright in 1951 of the great susceptibility to infection of unweaned mice about a week old, in which a paralytic disease accompanied by heart and muscle degenerative lesions followed by rapid death was reported. The other two are tissue culture methods and were reported in 1954. In the first, different dilutions of virus are inoculated into small cultures of cattle tongue epithelium in rows of cups on a 'Perspex' plate. After incubation at 37° C., complement-fixation tests are carried out on the plate and the virus titre determined. Three years ago it was shown by the Institute that the virus of foot-and-mouth disease can be grown also in pig and ox kidney tissue cultures, and employing cell monolayers with an agar overlay in the Dulbecco 'plaque' technique the fourth method of virus titration was developed.

Attention was directed in the demonstration to the usefulness of unweaned mice in other directions: for the passage of field samples to secure suitable virus titres for complement-fixation and other tests, for serum neutralization tests to confirm immunological type, and to follow antibody levels as a supplementary test in assessing the potency of vaccines. It has been found possible also to infect by inoculation chicks and chickens (1954) and chick embryos with greater regularity than had been conceived possible some years ago. Attention was directed to the significance of these findings in opening up fresh lines of investigation and the development of modified or attenuated strains for immunization purposes.

In the biochemical department the results of work indicating the value of the gel-diffusion technique for identifying the virus types, the number of antigens in virus preparations and the antibodies in serum from convalescent animals were set out. It has been shown, with the seven immunological types of foot-and-mouth disease and the two immunological types of the virus of vesicular stomatitis, 'Indiana' and 'New Jersey', that the precipitin lines are disease- and type-specific.

The results of continued studies in the biophysical department on the analysis of the structure of the virus of foot-and-mouth disease and the complex response it stimulates in the host were demonstrated. Two components of the virus with different biological activity have been separated by centrifugal analysis, one about 20 mμ in size and the other about 8 mμ (1952). Electron microscopic studies have now made it possible to study the structure of the virus particles and treatments which lead to their disintegration.

Space will not allow of detailed reference to other demonstrations in the fields of pathology and experimental cytology; or to the application of tissue culture methods, on a scale suitable for vaccine production; or on a more fundamental level to detailed studies, on the growth and multiplication of the virus in different tissues in suspensions of cells, or in single layers of cells on a glass plate and on the relationship between the virus and infected cells.

Visitors were able to inspect the vaccine production unit which has been installed to enable the Institute to gain experience in large-scale work and so designed that modifications in the methods of vaccine production or indeed completely new methods may be introduced. In the past fifteen years at Pirbright much experience has been gained in testing vaccines for safety and protective power. Charts of these tests were shown and the techniques described. The visitors were also able to see one of the three new additional isolation units, each one entirely self-contained, for experiments on large animals, and ten units in a separate area for holding cattle for long-term immunity tests. They also saw the breeding unit for small laboratory animals, which functions on a mass-production system. A selective breeding system is maintained by detailed recording, and careful attention to hygiene and sanitation makes it possible to maintain the steady output of healthy stock required by the laboratories, which is of the order of 250,000 unweaned mice and 30,000 guinea pigs per annum.

The problem of controlling foot-and-mouth disease is one for international collaboration, and it seems that Britain is making every effort to make useful contributions in an attempt to diminish the world incidence of the disease and ultimately to eradicate it from many countries in which, unlike Britain, it is endemic. The work of the Pirbright Research Institute is of the highest importance, not only in relation to the problem of foot-and-mouth disease, but also in the better understanding and control of virus infections throughout the world.

SOLAR GRANULATION AND ITS OBSERVATION FROM A FREE BALLOON

By Dr. D. E. BLACKWELL and Dr. D. W. DEWHIRST
The Observatories, University of Cambridge

AND

Dr. A. DOLLFUS
Paris Observatory (Astrophysical Section, Meudon)

Under good observing conditions, the surface of the Sun, which usually shows a slightly mottled appearance, breaks down into a much finer network of minute bright spots on a very slightly darker background. The existence of these irregular spots, which are about 1 sec. of arc in diameter, corresponding to 750 km. on the photosphere, has been known for nearly a century. This structure is called granulation. Treated at first as a curiosity and a test of resolution in a solar telescope, the study of solar granulation is now beginning to be of great importance in solar physics.

Detailed models of the solar atmosphere show that the layers below optical depth $\tau \sim 1$ are convectively unstable[1], suggesting that granulation is itself a convection phenomenon. It has been supposed that the individual granules are Bénard cells arising from convection. Two other lines of evidence support the view that granulation is associated with convection. First, it has been shown by Richardson and Schwarzschild[2] at the Mount Wilson Observatory, by McMath and others[3] at the McMath–Hulbert Observatory, and by von Kluber[4] at Cambridge, that when the slit of a high-dispersion spectrograph is placed across a solar image, the Fraunhofer lines in the spectrum show spiky projections both on their red and on their violet sides. Such observations give directly the line-of-sight velocities in the photosphere; but it is important to notice that they cannot give the velocities associated with individual granules. Because of the relatively long exposure times necessary in high-dispersion spectroscopy and the rapid fluctuations in the quality of the solar image, it is seldom possible to obtain a resolution on the Sun of better than 3 sec. of arc. This means that we must be content to measure the average line-of-sight velocity of an area of the photosphere which is likely to contain several ascending and descending currents.

The second line of evidence, that depending upon a quantitative study of the Fraunhofer lines averaged over a relatively large region of the solar surface, is less direct, but equally convincing. It also shows that the region in which the weaker Fraunhofer lines are formed is turbulent. However, care is necessary in comparing the results of these two methods of investigation because they may not refer to the same scale of turbulence.

The importance of granulation does not end here. It has been suggested by Biermann[5] that a sunspot is due to the inhibition of the convective transport of ionized gases by a magnetic field, and hence a reduction in the outward flux of energy. Schwarzschild[6] has suggested that the corona is maintained by the flux of mechanical energy from the convection zone. But in spite of its theoretical importance, the subject is still in an elementary state. The sole reason for this lies in the difficulties of observation. Even at the best observing stations, atmospheric turbulence rarely permits a day-time image quality of better than 1 sec. of arc. In addition, it is not easy to approach the theoretical definition of even a 10-in. telescope when the optical components are subjected to the full flux of energy from the Sun. Moreover, the granulation is a low-contrast subject. For these reasons, little is known about the true structure of the granulation. In spite of more than half a century of work, virtually nothing is known about the variation of the structure of the granulation with wave-length, and only little about its variation with distance from the centre of the solar disk. It is apparent that the subject will not advance appreciably until better observations are made. The best that can be done from a ground station is exemplified in the beautiful work of Rosch[7] at the Pic du Midi using a refractor of 10-in. aperture. It is unlikely that photographs showing better definition can be made from the ground, even from a selected observing station. The reason for this is that much of the 'bad seeing' during day-time is caused by turbulence in the lower levels of the atmosphere arising from the heating of the ground by the Sun. An observatory on a mountain top is not necessarily free from this disturbance. The thickness of this turbulent layer undoubtedly varies from day to day and is dependent on local conditions; but if observations could be made from the air at a height of about 20,000 ft. above local land masses, the deleterious effects of the turbulent air will usually be avoided and a great improvement in the quality of the seeing may be expected.

Some experiments along these lines were made in 1955 by two of us (D. E. B. and D. W. D.), working in co-operation with the R.A.F. A fused quartz flat was mounted inside the open door of a Lincoln aircraft and used to reflect sunlight into an 8-in refractor fitted along the fuselage. However, disturbed air near the door of the aircraft even at a height of 22,000 ft. and mechanical vibration limited the definition to 5 sec. of arc. In assessing the difficulties of this work, it is helpful to bear in mind that photographing the Sun with the best resolution so far attained is equivalent to taking a legible photograph of the word 'NATURE' on the cover of this journal from a height of 2 miles. If worth-while progress is to be made, this limit must be decreased at least by a further factor of two.

To obtain the required definition, the ultimate aim must be to operate the telescope in quiescent air at such a height that it is above all the more grossly disturbed parts of the atmosphere, and the only practicable way to do this is to mount the telescope beneath a floating balloon. In 1956, work was begun at the Cambridge Observatories, in collaboration with the Paris Observatory, to investigate this possibility. One of us has already demonstrated the feasibility of making astronomical observations from a manned balloon[8]. A more detailed account of the apparatus used in a first flight and the results obtained with it has already been published elsewhere[9,10]. The telescope was of 11-in. aperture, and was guided manually on the Sun. Accurate guiding is very difficult, and the only reason why an experiment of this kind is practicable is that it is possible to take photographs with an extremely short exposure time. The exposure on the first flight was about 2 msec., but this was

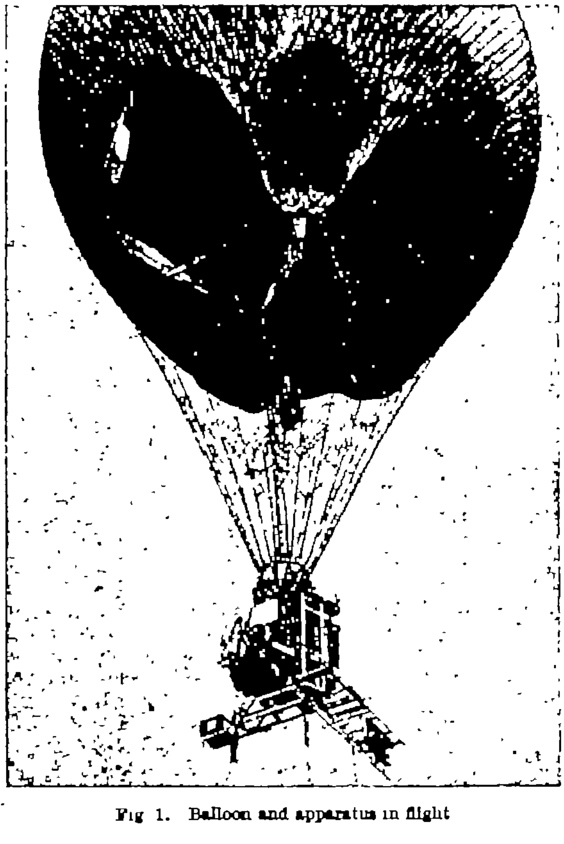

Fig 1. Balloon and apparatus in flight

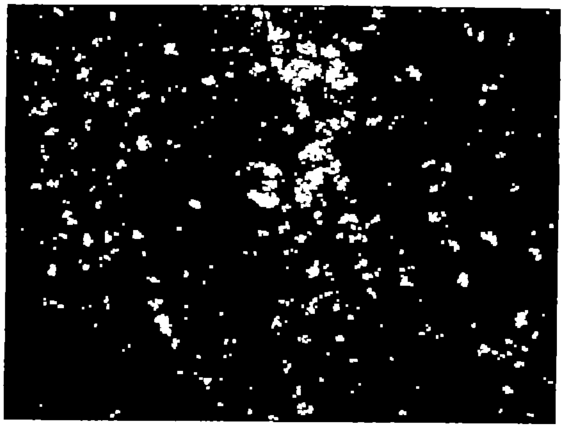

Fig. 2. A part of one photograph of the solar surface. Individual granules are mostly about 1·3 sec. of arc in diameter, but on the original negative smaller features can be distinguished

found to have been too long to counter the effect on the image quality of bad guiding, and the photographs show a sheared structure. For a second flight, therefore, this shutter was replaced by one operating at about 0·2 msec. This flight was made on April 1, 1957, from the Meudon Observatory outside Paris (observers A. D. and D. E. B.). A photograph of the apparatus and balloon in flight is shown in Fig. 1. A height of 18,000 ft. was attained and 480 photographs taken during a period of three hours.

Among other difficulties is that of predicting with sufficient accuracy the change of focus of a refracting telescope with altitude. The change may be as much as 2 mm. in a focal length of 3,000 mm., and as the focus is critical to 0·1 mm. it is necessary to take photographs over a range of focus settings. For this reason alone only one photograph in fourteen can show acceptable definition. However, the best photographs obtained are of excellent quality, and one photograph in particular appears to be at least the equal of any other that we have seen. A part of this photograph is reproduced in Fig. 2. Analysis of the photographs is still in progress, but it seems likely that the theoretical limit of resolution of the 11-in. objective has been reached. The ground-level seeing at the time of the flight was of poor quality, and the success of the photographs demonstrates that high-altitude observations of this kind are a feasible method of overcoming the previously insuperable difficulty of bad seeing. Plans for further flights with a larger telescope are now under discussion.

This investigation has been financed chiefly from a Royal Society Government Grant, with help from French special funds.

AVOIDANCE OF COLLISION AT SEA AND IN THE AIR

A JOINT meeting of the Institute of Navigation, l'Institut Français de Navigation and the Ausschuss für Funkortung was held at the rooms of the Royal Geographical Society during June 5–7, on "The Avoidance of Collision by Airborne and Shipborne Means".

Collisions at Sea

Though the meeting was short it was most useful because it served to demonstrate the various points of agreement and controversy on a matter which is complex and subject to a good deal of public comment, not always informed. As the prevention of collisions at sea is an international matter, it is extremely valuable to discover the bases of common and contrary opinion by free and international discussion before the regulations come under review in the more inhibited atmosphere of a formal conference.

After a disquisition on the mathematics of collision avoidance, the meeting was invited to consider the causes of collision at sea, despite the use of radar, then the possibilities of avoidance by manœuvre and, finally, the contribution which electronic or other equipment may make, or be asked to make, to ease the task of the navigator in this regard. Fog or low visibility was assumed throughout.

On the first point there was no disagreement whatever. Speakers only differed in their manner of expressing the failure of the human element to understand the problem it was facing, or to make even reasonably good use of their equipment. It must be said at once that in most of the accidents described in which one of the ships was without radar, that ship usually had to carry a substantial and sometimes a major share of the blame.

The main failure in the radar-fitted ships seemed to be philosophical or psychological rather than technical, in the navigational or electronic senses; inability to understand that the danger mounts at an increasing rate as ships approach one another without reducing speed; failure to appreciate the importance of continuity of radar watching and of forming the habit of regular and precise observation. Some speakers mentioned lack of self-discipline and sense of responsibility and another suggested the necessity of breaking down the feeling of personal immunity from disaster, which is common to other walks of life.

The view was unanimous that better training was essential and that it should include instruction in the non-technical aspects just mentioned. There was no dispute concerning the need for seamanlike caution when interpreting the rule calling for moderate speed, or for progressive reduction of speed when approaching a close-quarter encounter. Of the twenty-eight ships involved in the collisions analysed by one speaker, twenty were found by courts or inquiries to have been going too fast, and several maintained their speed up to the point of collision.

Controversy became apparent when consideration of manœuvring to avoid collision opened. The need for studying this subject arises from the agreed presumption that the present steering rules, that is, 'giving way' ship and 'standing on' ship, can only be applied between ships in sight of one another. In fog, therefore, there is a period, long or short, between radar contact and hearing or seeing the ship at close quarters, during which ships are under no obligation except to sound fog signals and go at a 'moderate' speed.

There are two main schools of thought on this subject, one which would strictly limit manœuvre to reduction of speed and to starboard alteration of course, and the other which would leave the choice to the seaman, presuming him to have been educated thoroughly in all aspects of technique and philosophy. The objection to restraint is that a rule to cover all situations will fail if it is too precise. Naturally this controversy remained unresolved and will no doubt be given much more thought.

On the subject of amending the collision regulations to take account of radar, diverse opinions were expressed. Some were in favour of special sound signals being provided to indicate that the ship was using radar. Others felt that this would lead to possibly dangerous assumptions as to both the intentions of the ship using it and the identity between the fog signal and some particular echo on the radar screen. All suggestions for amendment were left for further study, but the conclusions of the meeting expressed the need for attention to be paid to the interpretation, in the radar context, of the rules for moderate speed, altering course when at close quarters and stopping even before the fog signal is heard.

The subjects discussed under the heading of assistance from electronic or other equipment are best considered in two categories, depending upon the echo alone or on active co-operation from other ships; these categories also define opposing schools of thought.

On the whole, the former school found more support at the meeting than the latter, although one or two speakers did press the claims of the identification of ships whose echoes are seen, so that conversation or other means of exchanging intelligence may be established. The opposing case was that unless the complex and costly equipment needed was applied to all ships, whether radar-fitted or not, and was 100 per cent reliable, the navigator might be little better off. Further, if conversation and mutual agreement were to be the ultimate aim, it would involve severe language difficulties and radio congestion, both of which would give rise to delays intolerable in the circumstances. Further, the value of bi-lateral arrangements in multi-lateral and dynamic situations is, to say the least, doubtful.

There was no suggestion that electronics could not meet the requirement if it were to be posed, but there was no doubt that a system to provide precise radar identification for each of, say, 15,000 ships would be costly. If automatic coded transmission of course and speed information was needed the cost would rise, while if conversation were to be the aim, very high-frequency radiotelephone equipment would need to be provided universally.

The policy of depending upon the echo alone was shown to have two distinct channels, one dealing with echo movement and the other with echo shape. The object of both is to present the radar observer as rapidly as possible with intelligence concerning the course and speed of the ship whose echo is seen. With the ordinary marine radar of to-day, the orientation of the ship can be judged from the shape of her echo only in exceptional circumstances.

Systems which operate on echo movement vary, from the simple plotting by hand of measured radar ranges and bearings, to the recently launched 'true-motion' radar or the development of storage tubes (cathode ray tubes) on which the 'painted' path of an echo can be retained at will. Speakers extolled each of the modern devices and even combinations of them. Their advantages over manual plotting are first that the information-rate is much better, and secondly that the observer has less to do and less chance of making errors.

Dependence on the shape of the echo implies a very high degree of discrimination, and this is available in the greatest degree at the present time in the Q-band (8 mm.) radar, demonstrated by the Decca Radar Co., in England, and Messrs. Philips in Holland. It is still in a somewhat embryo state but, as the meeting was told, it does show the orientation of a 300-ft. ship at about 5 miles. An 8 mm. radar with a 12-ft. scanner will have a beamwidth of about 0·15°, providing 8 times better discrimination than a normal 3 cm. radar with a 6-ft. scanner. The speaker who favoured this system pointed out that such refinement in definition would make the heading of another ship evident from a glance at the echo, provided that it was within a certain range.

At longer ranges the heading will not be discernible from echo-shape, whereas with the echo-movement systems the effect of increased range is to decrease the information-rate. However, on balance the speaker was in favour of the echo-shape principle. He pointed out the susceptibility of the Q-band radar to interference from rain clutter; this and its shortcoming in maximum range make debatable its use as the only radar set in a ship.

The conclusions reached by the meeting showed that there was unanimity in assigning the blame for most of the collisions which have occurred to the human element, which often failed to appreciate the risks inherent in entering close-quarter situations at speed and to understand the limitations of and the best ways of using radar equipment. More and better training is needed in using radar and in the mental approach to encounters in fog, attention being devoted particularly to continuity of radar observation, and to reduction of speed and holding course when at close quarters.

The meeting hoped that technical advances would continue and be given impetus and direction by the studies of a working party which might be set up to consider the unsolved problems. F. J. Wylie

Collisions in the Air

At present collision avoidance in the air is based on visual avoidance manœuvres by pilots and, during poor flight visibility, on separation of aircraft under instructions of the air traffic control service on the ground. Separation by air traffic control is confined to the vicinity of airports and main air routes. The proposal to use airborne devices for collision avoidance is a comparatively recent one, and no such device has yet been produced. For these reasons, the discussions during the air sessions were mainly exploratory, to determine the possible roles of such devices and possible principles of design. It was considered premature to make any recommendations at this stage, but the meeting was valuable in allowing a free exchange of views between those present, including specialists in many fields from the three countries and a guest speaker from the United States who has made a study of the physics of air collision avoidance.

The discussions were in three main parts. The first dealt with the statistics of air collisions and the mathematics of collision avoidance manœuvres. The second session considered air traffic control from the point of view of its limitations as a method of preventing collisions in all weather conditions and in all areas. The third session was devoted to possible airborne solutions.

The statistics of collision incidence were from the United States, because flying is practised on a sufficiently large scale in that country for the number of collisions occurring over a few years to have statistical significance. These statistics show that the overwhelming majority of collisions occur in good flight visibility; most are near airports and most are cases involving overtaking. From this evidence it is apparent that complete reliance cannot be placed on visual avoidance even in good visibility. Among reasons for this examined at the meeting were the extremely restricted field of view from aircraft cockpits due to fuselage streamlining; lack of aircraft conspicuity, especially against the Sun; physiological limitations of the human eye, such as the difficulty in focusing to infinity in the absence of a defined horizon or cloud; and psychological factors conditioning the quality and speed of the pilot's reaction to the collision hazard.

While much could be done to improve these conditions, it was agreed that such improvements could be no more than palliatives, especially taking into account the very high speeds of jet aircraft, which make visual collision avoidance virtually impossible.

The mathematics of collision avoidance in the air differs from that of the marine problem in several respects. The very much higher speeds of closing allow less time to make a decision, and if a turn is made it will probably need to be sustained until the other aircraft is passed. Apart from this, there is the possibility of using the third dimension. The effectiveness of an avoiding manœuvre can be expressed statistically, depending upon the probable accuracy of the parameters measured by the warning system. If the system is self-contained, that is, if it does not work in co-operation with a transmitter on the other aircraft, its effectiveness will depend on the accuracy of measurement of rate of change of relative bearing between the aircraft, or rate of change of speed of closing, both of which are zero in the collision case. It was pointed out that the accuracy with which these rates must be determined to distinguish the collision case is so high that it is only when aircraft are within comparatively short range that such rates can be distinguished from random perturbations of the aircraft in its flight. A warning time of thirty seconds seemed to be the practical maximum for such self-contained systems. These limitations do not, however, apply to co-operative systems, wherein a responding beacon in the other aircraft could continuously transmit its heading, speed and flight altitude if necessary, thus enabling the collision triangle to be solved continuously in the interrogating aircraft.

It seemed to be accepted by the meeting that air traffic control from the ground is necessary in areas of high traffic density, irrespective of any airborne device, to cope with the situation where several aircraft may present a mutual collision hazard and to maintain an orderly flow of traffic into and out of the airports. Separation of aircraft by control from the ground does, however, involve path restriction and delays, and is therefore generally confined to conditions of poor visibility, including night flying. A device which would assist pilots by warning them of the presence of other aircraft in good visibility might be a better solution than extending air traffic control separation to all weather conditions. The air traffic control service is further confined at present to the vicinity of aerodromes and to established air routes. The device mentioned could provide protection in other areas not so served.

On long-distance routes, for example, over the North Atlantic, where navigation and communication facilities are limited, very large separations between aircraft have to be imposed by air traffic control to allow a margin for navigation errors. This results in artificial congestion, including restriction of cruising altitudes, though the actual traffic density in physical terms is extremely low. There are two alternative approaches to this problem. The first is to depend entirely on better navigation and communication facilities and to lay down a system of alternative fixed routes to improve the control system. The second is to replace or supplement air traffic control from the ground by the use of airborne collision-warning devices. Operators are likely to continue to require freedom in choice of path on such long-distance routes, in order to take maximum advantage of the wind distribution in achieving minimum flight time and therefore operating economy. Such flexibility may be difficult to achieve with the complex route network necessary for separation of aircraft entirely by air traffic control. Opinions at the meeting differed on the extent of this difficulty. Using airborne collision-warning devices, there need be less restriction of flight paths, and it was generally accepted by the meeting that such devices in one form or another were desirable on such long-distance routes. They have the advantage of avoiding continuous restriction of aircraft flight path in order to cater for the very remote contingency of conflict with an aircraft on an adjacent path.

A number of different applications were suggested for collision-warning devices, and the type of device required may vary with these different roles. For example, a system for use in good visibility in areas of high traffic density would need to be limited in range to prevent too many spurious warnings. A system for use on long-distance routes where traffic density is much lower could be of longer range and so give the pilot sufficient time to assess the situation and perhaps, in co-operation with air traffic control, change altitude to avoid the other aeroplane. During the session on airborne solutions various possible principles of operation for collision-warning systems were examined, but no system has yet been proposed capable of giving a universal solution to the problem, that is, covering all possible danger sectors with every combination of aircraft speeds. Doubt was expressed at the meeting whether a self-contained system is feasible, but study is continuing because such a device would have the tremendous advantage of giving immunity from all aircraft, and would not necessarily require universal adoption and standardization of design. Co-operative systems using equipment in both aircraft certainly seem more feasible, and various radio and radar techniques were discussed in relation to such devices. This is a field wide open for further study and invention.

Although no formal conclusions were drawn from this meeting, the discussions did show that there are several distinct possible roles for air collision-warning systems, and that their introduction may be inhibited by an attempt to fill all these roles with one infallible device. For example, a fairly simple system might be developed to provide proximity warning when overtaking another aircraft in visual conditions. This might warn the pilot of the presence and direction of the other aircraft, so that he could make an avoidance manœuvre visually. Such a device might have prevented the Grand Canyon disaster last year, and other similar accidents. It is possible that operational experience, gained by the use of comparatively simple devices of this kind, will indicate the lines for more advanced developments.

D. O. FRASER

NEWS and VIEWS

British Museum (Natural History) :

Dr. H. W. Parker, C.B.E.

IT has recently been announced that Dr. H. W. Parker, keeper of zoology in the British Museum (Natural History), is to retire on October 1. His tenure of the keepership has been outstanding for his introduction into museum practice of the principle that species are live populations in Nature, varying in time and in space, affected by ecological and geographical factors, and requiring statistical treatment of large samples and study in the field. No longer can it be said that a species is what resembles a particular specimen stuck on a pin in a museum. Dr. Parker's numerous publications reflect this infusion of the 'new systematics' into museum taxonomical work, and his monographs on the lizards of Somaliland, the Microhylid frogs and the Leptodactylid frogs are universally regarded as classical contributions to the subject.

Dr. F. C. Fraser

DR. F. C. FRASER, who succeeds Dr. Parker, brings to the keepership of zoology a fundamental training in the principles of taxonomy and a long career of research into the life, structure and function of whales. In investigations undertaken under his supervision, the significance of the sounds emitted by whales under water has been elucidated by means of researches into the structure and function of the auditory apparatus, which show that whales are enabled to detect the direction from which the sounds come. This is a fundamental necessity for the continuance of the species by enabling the animals to meet in a medium where the senses of smell, sight, taste and touch are unavailing. In a recent communication in *Nature*, Dr. Fraser and one of his colleagues have put forward a new and objective explanation of the 'blow' of whales which seems likely to prove a major contribution to the solution of an age-old problem.

Mr. J. D. Macdonald

MR. J. D. MACDONALD is succeeding Dr. Fraser in the deputy keepership of zoology. Mr. Macdonald has been in charge of the Bird Room at the British Museum (Natural History) since 1944, and has been responsible for the new Bird Gallery and British Bird Pavilion which have met with great favour from visitors. He has travelled far afield in connexion with his researches, and went on ornithological expeditions to the Southern Sudan and to South-West Africa, whence he brought back valuable collections.

Geography at Bristol : Prof. W. W. Jervis

ON the evening of June 14 a large company of past and present students of the Department of Geography in the University of Bristol bade farewell to Prof. W. W. Jervis, who retired from the chair of geography at the end of the academic year. Prof. Jervis, geographer and barrister-at-law, is a graduate of the University of Durham, having been a student at Armstrong College, Newcastle, before the First World War. His first appointment was as lecturer in mathematics and geography at Exeter in 1913. Shortly afterwards he was on active service, chiefly on the North West Frontier of India and in Mesopotamia. In 1919 he was appointed lecturer in geography in the University of Bristol and began to build up the now flourishing and active Department. Created reader in geography in 1926, he was elected to the first chair of geography in the University of Bristol in 1933. The events of the Second World War called a halt to further developments and the Department of Geography did not escape the damage inflicted upon Bristol and its University. During part of the War Prof. Jervis was again in uniform, commanding the 9th Gloucestershire Battalion of the Home Guard. On the return to peace-time conditions, Prof. Jervis and his colleagues faced the problems common to all universities against a background of re-creating a Department with its essential physical resources. There has been one very clearly marked feature of the work instanced in the Department's well-known and deserved reputation in surveying, reflecting Prof. Jervis's own interest in all matters appertaining to cartography. The spread of his graduates over many fields of employment and areas in the world is in itself a tribute to the achievements of the retiring professor.

Prof. R. F. E. W. Peel

PROF. W. W. JERVIS is to be succeeded at the University of Bristol by Prof. R. F. E. W. Peel, of the University of Leeds, who graduated at Cambridge in 1934. His first university appointment was in the Department of Geography, King's College, Newcastle upon Tyne, in 1935. In 1938 he was granted leave of absence to join an expedition to Libya under the leadership of Bagnold, and his abilities as a geographer and anthropologist (he took the diploma in anthropology at Cambridge in 1935) were shown in both his contributions in the field and in published papers on his return. On the outbreak of hostilities in 1939 he was commissioned in the survey branch of the Royal Engineers, and he was among those evacuated from Dunkirk. Following a period of service in England he was posted to Italy and was in charge of the map production branch of the Survey Directorate. At the end of the War he returned to his post at King's College, Newcastle, but shortly afterwards was appointed to the staff of the Department of Geography at Cambridge. When the University of Leeds created an additional chair of geography, Prof. Peel was appointed to fill it and on the retirement of Prof. A. V. Williamson he became head of the Department. While at Leeds, in addition to obtaining and occupying new premises, Prof. Peel has visited East Africa and Canada, and sustained his interest in problems of the physical geography of northern England. His teaching and research interests are not, however, narrowly confined, and in the Bristol environment he will find satisfaction in the developments there in surveying and cartography, as well as in physical and human geography.

Second Geneva Conference on Peaceful Uses of Atomic Energy

THE second International Conference on the Peaceful Uses of Atomic Energy is to be held in Geneva during September 1–13, 1958. A provisional agenda has been agreed by the seven-nation Advisory Committee, of which Sir John Cockcroft is the member for the United Kingdom, providing for twelve plenary sessions embodying papers of a general survey type, and four parallel series of technical sessions covering the following subjects: Series 1: chemistry and the chemical processing of irradiated fuel, reactor technology, radiation damage in reactor materials, handling of highly irradiated materials, treatment of radioactive wastes; Series 2: nuclear physics including the physics of fission and fusion reactors, reactor theory, fuel cycles and the economics of nuclear power, research, test and prototype power reactors, reactor experiments; Series 3: production and uses of isotopes and ionizing radiations in research, medicine, agriculture and industry, dosimetry, biological effects of radiation, radiological protection, reactor safety and location, meteorological and oceanographical aspects of the large-scale use of atomic energy; Series 4: raw material supplies, winning and refining of uranium and thorium, methods of separation of isotopes, metallurgy and fabrication of fuel elements, processing of other nuclear materials.

The Conference will be conducted under the same rules of procedure as in 1955, which are published as Annex 2 in Vol. 16 of the Proceedings of the International Conference on the Peaceful Uses of Atomic Energy. Officials of the Conference, including the president, secretary-general and chairmen of the technical sessions, will be announced later. Arrangements for participation by the United Kingdom are being organized through an Executive Committee (chairman, Sir John Cockcroft; secretary, Mr. B. W. Mott) and a Papers Committee (chairman, Dr. B. F. J. Schonland; secretary, Dr. T. A. Hall) on which are representatives of the U.K. Atomic Energy Authority, the Central Electricity Authority, industry, universities and other bodies. Titles and 500-word abstracts of papers must be in the hands of the secretary-general of the United Nations by March 1, 1958, and final texts by June 1, 1958. At present the Papers Committee is engaged on the compilation of a provisional list of titles, with the object of estimating the number of papers likely to be submitted from the United Kingdom and their distribution between the various sessions. It is hoped that this information will be available by September 1, 1957. Organizations represented on the Papers Committee will be approached by their representatives for contributions, but others should communicate directly with the Papers Secretary, at the Atomic Energy Research Establishment, Harwell, Berkshire, if they have titles to submit or if they require further information. Inquiries concerning matters other than the submission of papers should be addressed to the Secretary of the Executive Committee, at the same address.

U.S. National Science Foundation Research Grant for Aslib

THE United States National Science Foundation has made an award of £10,000 to Aslib for research into the comparative efficiency of various indexing and literature search systems. The research programme, which is expected to take two years, is to be conducted at the College of Aeronautics, Cranfield, under the direction of Mr. C. W. Cleverdon, librarian of the College. Many new techniques have been evolved in recent years in an effort to overcome the problems created by the vastly greater flow of research papers and the increased need to locate information due to the growing complexity and volume of scientific and industrial research. The research which has been planned is intended to provide evidence as to whether and in what circumstances one indexing system is more efficient than another. First, some 20,000 research reports on aeronautical engineering matters will be indexed under five different systems. Strict controls, covering time and other relevant economic factors, will be maintained at all stages of the work. When this has been completed, it is intended to carry out exhaustive tests on the indexes in order to show their comparative efficiency in varying conditions.

Journal of Electronics and Control

STARTING in July with the first number of Vol. 3, the *Journal of Electronics* will contain an additional section dealing with control systems and mechanisms and its title will be changed to *Journal of Electronics and Control*. The Electronics Section will continue to publish papers devoted to all aspects of electron science as heretofore, and the new control section, which will be the responsibility of the recently appointed assistant editor, Mr. J. R. Day, will consist of contributions on any aspect of the science of control, either fundamental or arising in the context of industrial or other problems. The principles of detection and measurement, process control, the control of electrical and mechanical quantities in the field of servo-systems, the applications of electronic devices to control systems, and the automatic handling of data come within its purview, but not the study of organizational, economic and psychological factors involved in control engineering. Space will still be reserved in each number for book reviews, news items and correspondence. The number of pages will be increased from 100 to 130, and for the time being the frequency of publication of the *Journal* will remain unchanged—six parts per annual volume. There will be no increase in the annual subscription rate or in the price per single copy.

British Steel Castings Research Association

THE British Steel Castings Research Association has entered into an arrangement with the Steel Founders' Society of America for the exchange of information at their respective annual conferences. Each Association will, in alternate years, invite the other to nominate a speaker to address its annual conference on a selected subject. The scheme is being initiated this year with an invitation to representatives of the British Steel Castings Research Association to address the Steel Founders Society of America Technical and Operating Conference, to be held in Cleveland, Ohio, during November 11–13, on the subject of the application of the graphite-rod resistor furnace to steel foundry practice, and the use in steel foundries of the immersion pyrometer for the measurement of liquid steel temperatures. This paper will be presented by Mr. T. A. Cosh, head of the British Steel Castings Research Association's steelmaking section, and Mr. L. W. Saunders, chief metallurgist, Lake and Elliot, Ltd.

British Iron and Steel Institute Translation Service

AT the suggestion of the British Iron and Steel Research Association, the Iron and Steel Institute has agreed to organize a co-operative translation service. Plans are already well advanced, and a number of companies in the industry are collaborating with the Institute in setting up the service. The scheme will benefit the industry in two ways: not only will the range of available translations of foreign technical papers, including Russian publications, be considerably widened, but also much unnecessary duplication of effort will be avoided. Translations prepared by individual companies will be passed to the central 'pool', and these will be supplemented by translations from other sources. An index is currently being compiled of those translations made since 1950 which are still available, and lists of newly produced material and of translations in course of preparation will be published at regular intervals by the British Iron and Steel Research Association, the British Iron and Steel Federation and the Institute itself. Although primarily devised to serve the needs of the iron and steel industry, the new service will nevertheless be available to all who wish to take advantage of the facilities offered. An agreed scale of charges has been laid down which includes provision for substantial reductions where a number of copies of any individual paper are required. Inquiries should be addressed to the British Iron and Steel Research Association, 11 Park Lane, London, W.1.

International Group for the Study of the Fauna of the Soil

DURING the Sixth International Congress of Soil Science held in Paris in 1956, zoologists specializing in the study of the fauna of the soil formed an international group with the object of providing a means for the exchange of information among workers in this field. To achieve this aim, a *News Bulletin* is being published, and in addition international colloquia on particular aspects of the subject will be held at intervals. The first number of the *Bulletin*, which appeared in May, includes a questionnaire requesting details of current research projects together with information of animal groups studied. The results of this inquiry will be published in future numbers of the *Bulletin*, copies of which can be obtained from J. d'Aguilar, Station centrale de Zoologie agricole, Route de St.-Cyr, Versailles. The first colloquium, devoted to "Methods of Research in Soil Zoology", will be held at Rothamsted Experimental Station, Harpenden, Hertfordshire, during July 10–14, 1958, immediately prior to the International Zoological Congress to be held in London during July 16–23. The next issue of the *News Bulletin* will give the programme and other details of the colloquium.

Sugar Research in Mauritius

THE annual report for 1956 of the Mauritius Sugar Industry Research Institute (pp. 92+xx. Réduit, 1957) includes papers on cane breeding, nutrition, soils, diseases and pests, weed control, cultivation and irrigation, effects of rainfall on production, and sugar manufacture. Both the total sugar production and the yield per unit area established new records. Only a few points from the research reports can be noted here. Breeding and selection studies have been continued along the usual lines for the crop. The induction of arrowing, that is, flowering, by photoperiodic treatments is to be attempted. Some interesting information has been obtained from mineral analyses of the juice of six cane varieties grown under different conditions of fertility and climate. For potassium, magnesium and calcium a strong varietal effect was found; for phosphate, however, the varietal effect appears to be weak with the varieties tested. The generally lower status of juices from high rainfall areas in all minerals has been noted. From the results obtained it would appear that the effect of increasing nitrogenous fertilization on the potassium and phosphate contents of juice is governed by whether or not an increase in yield occurs. With an increase in yield both potassium and phosphate decrease, but when no increase in yield is obtained the potassium and phosphate levels of the juice remain approximately constant irrespective of the amount of nitrogen applied to the crop. Foliar diagnosis has been used to advantage in determining the nutritional requirements of sugar cane in different areas. Indeed, the year 1956 marks the end of the first decade of organized control of fertilizer treatment, chiefly phosphate and potassium, based on this technique.

Auxin Inhibition in *Lunularia*

IN the course of earlier investigations of the gemmæ of *Marchantia* and *Lunularia*, the possible existence of the phenomenon of apical dominance, as exemplified by the higher plants, was noted by C. D. LaRue and S. Narayanaswami. It is well known that the gemmæ of liverworts do not germinate within the gemma cup unless they are detached from the thallus, nor are adventitious buds formed on healthy thalli. These and related observations suggested a programme of investigations from which some interesting results have accrued (*New Phytol.*, 56, 61; 1957). Using *Lunularia*, it was found that excision of the upper halves of thalli above the gemma cups caused the gemmæ within the cups to germinate. Mutilations such as puncturing, slitting, excision of wings, etc., did not affect the gemmæ so long as the apical notches and the midrib regions were intact. This indicates the action of auxin inhibitors from the tips of thalli rather than the effect of a wound stimulus. The upper halves of thalli isolated by transverse cuts do not regenerate adventitious buds, whereas the basal halves do so from the cut ends. The regenerated apical buds cause retardation of the growth of gemmae in the same way as the original ones. Surgical experiments indicate the basipetal movement of inhibitors. Applications of growth hormones, such as indolylacetic acid, indolylbutyric acid and naphthaleneacetic acid in lanolin or in agar blocks, to the cut ends confirm the inhibiting influence of the apical notch and the latter as a centre of synthesis of inhibitors. Positive results for the formation of auxin have been obtained with *Avena* tests of the extracts of thallus tips. Preliminary experiments with analysis of such extracts by paper chromatography suggest that the auxin involved may be indole acetic acid.

Measurement of Body Radioactivity

The papers given at a conference on the measurement of body radioactivity held at Leeds on April 16–17, 1956 (*Nature*, 178, 172; 1956), have recently been published (*Brit. J. Radiology*, Supp. No. 7. Pp. vi+130. London: British Institute of Radiology, 1957. 25*s*.). Measurements of body radioactivity were originally undertaken to measure the body burden of workers who had been exposed to radium and radon and of patients who had been injected with contrast-media containing thorium. Wider use will now undoubtedly be made of the techniques used in these investigations in determinations of the incorporation of fall-out in human populations. The radium content of the body of a chemist who died at the age of seventy-four after working for thirty-four years with radioactive materials was determined by workers in four independent laboratories. The reasonably good agreement of the results obtained by scintillation counting, ionization chambers and autoradiography gives confidence in the methods.

The admirer of big apparatus will enjoy the description of high-pressure ionization chambers containing 3,000 litres of gas at 20 atmospheres pressure, and of an instrument in which 108 photo-multipliers view the scintillations in 500 litres of liquid with a sensitivity of the γ-ray equivalents of 10^{-9} to 10^{-10} gm. radium in equilibrium with its daughter substances. The NaI–Tl crystal spectrometer developed by Marinelli and his collaborators shows the trend towards simpler instruments. The volume contains much information on many related topics like background radiation and the radium-content of drinking water in many parts of the world. It is very well produced, but summaries might have been added to the papers.

Algebraic Transformations to a Normal Population

An interesting application of the use of an algebraic transformation of a variable to obtain a normal population is provided by a report, "Distribution conjointe de la température et de l'humidité de l'air au Congo Belge" (Publications de l'Institut National pour l'Étude Agronomique du Congo Belge, Bureau Climatologique. Communication No. 14. Pp. 31. Brussels, 1957), by Dr. F. Bultot. The problem related to the determination of the range within which 95 per cent of values of atmospheric vapour pressure occurred at specified temperatures in the Belgian Congo. Annual and monthly means of temperature and vapour pressure and even annual monthly means of the values for each hour were inadequate to give the limits needed. If the variables are normally distributed the range can readily be determined by drawing the ellipses of bivariate distribution. The actual temperatures and vapour pressures were found, calculating the coefficients of kurtosis and disymmetry, to have quite skew distributions. The values of the logarithms to base 10 of the temperature and of the cube of the vapour pressure, however, were found to be nearly normal. The standard deviations of these quantities, and the correlation coefficient between them, were calculated and the ellipses drawn. Figures for a number of places in the Congo are given, showing the ellipses corresponding to 95 and 99 per cent of the number of observations, with corresponding diagrams obtained by transforming back to direct values.

French Metallurgical Society

The French Metallurgical Society is to hold its autumn meeting in Paris at l'Ecole Nationale Supérieure de Chimie, 11 rue Pierre-Curie, during October 7–12. At the meeting the following awards will be presented: the Grand Medal of the Society to Prof. G. Chaudron, for his services to metallurgy; and the Rist Prizes to G. Pomey and A. Gueussier. The programme of the meeting includes sessions on metal fatigue, rheology of metals, metallurgical problems posed by atomic power, the physics of metals and the physical chemistry of alloys. Further details can be obtained from the Société Française de Métallurgie, 25 rue de Clichy, Paris 9.

Manchester Literary and Philosophical Society

The Manchester Literary and Philosophical Society recently elected the following officers for the year 1957–58: *President*, Dr. F. C. Toy; *Vice-Presidents*, Miss A. C. Alexander, Sir Geoffrey Jefferson, Prof. J. Kenner, Dr. Norman Smith; *Hon. Secretaries*, Dr. L. Cohen, F. Willett; *Hon. Treasurer*, H. Hayhurst; *Hon. Librarians*, L. L. Ardern, Dr. W. H. Brindley; *Hon. Curator*, N. G. C. Pearson.

Carlsberg–Wellcome Travelling Fellowships Awards

The Carlsberg Foundation (Copenhagen) and the Wellcome Trustees (London) announce that the awards of Carlsberg–Wellcome Travelling Fellowships for the academic year 1957–58 (*Nature*, 179, 658; 1957) have now been made. Mr. Jørgen Berger, the Danish Fellow, a member of the teaching staff of the Department of Organic Chemistry, Denmark Pharmaceutical College, will study techniques of organic ultra-microanalysis with Dr. R. Belcher in the Chemistry Department at the University of Birmingham, and Dr. Stephen Paget Lapage, the British Fellow, who is a trainee member of the Public Health Laboratory Service, will work at the State Serum Institute, Copenhagen, on the biochemical and serological identification of enterobacteriaceae.

Oversea Service Division, Colonial Office

The following appointments have recently been made in the Oversea Service Division, Colonial Office: C. E. Johnson (chief agricultural officer, Northern Rhodesia), assistant director of agriculture, Northern Rhodesia; J. V. Webdale (agricultural officer, Tanganyika), agricultural officer, Zanzibar; J. Blackburn (chemist, Tanganyika), assistant government chemist, Northern Region, Nigeria; A. F. A. Lamb (conservator of forests, Trinidad), chief conservator of forests, Sierra Leone; D. A. Harkin (geologist, Geological Survey Department, Tanganyika), deputy director of Geological Survey, Tanganyika; A. M.

Quennell (deputy director of Geological Survey, Tanganyika), director of Geological Survey, Tanganyika; D. H. Romney (scientific officer, British Honduras), senior scientific officer, British Honduras; R. H. Regnault (surveyor, Fiji), deputy director, Lands, Mines and Surveys, Fiji; A. L. C. Thorne (senior veterinary research officer, Federation of Nigeria), deputy director of veterinary research, Federation of Nigeria; J. Armstrong, agricultural officer, Northern Rhodesia; T. R. Barnes, agricultural officer, Western Region, Nigeria; W. J. R. Boyd, agricultural officer, Northern Rhodesia; A. J. M. Gunn, agricultural officer, Tanganyika; D. J. H. Jones, agricultural chemist, Northern Rhodesia; W. Keir, agricultural officer, Kenya; J. H. Simons, plant protection officer (plant pathologist), Western Region, Nigeria; C. R. Cratchley, geologist (geophysicist), Federation of Nigeria; J. B. Wright, geologist, Kenya; J. Ashton, senior surveyor, Northern Region, Nigeria; A. G. Bailey, scientific officer, Northern Region, Nigeria; C. M. Leslie, scientific officer, East African Industrial Research Organization, East Africa High Commission.

University News: London

THE title of professor emeritus in the University of London has been conferred on the following: Prof. C. W. Dannatt, on his retirement from the chair of metallurgy at the Imperial College of Science and Technology; Prof. J. B. S. Haldane, on his resignation from the Weldon chair of biometry at University College; Prof. B. J. Lloyd-Evans, on his retirement from the Kennedy chair of mechanical engineering at University College; Prof. W. H. Pearsall, on his retirement from the Quain chair of botany at University College; Prof. William Wardlaw, on his retirement from the chair of physical chemistry at Birkbeck College.

The following appointments are announced: Dr. Douglas McKie, reader in the history and philosophy of science at University College, to the University chair of the history and philosophy of science tenable at that College; Dr. M. Freedman, lecturer in anthropology at the London School of Economics and Political Science, to the University readership in anthropology tenable at that School; Mr. S. J. Gould, lecturer in sociology at the London School of Economics and Political Science, to the University readership in social institutions tenable at that School; Dr. P. L. le Roux, senior lecturer at the London School of Hygiene and Tropical Medicine, to the University readership in medical parasitology tenable at that School; Dr. J. F. Sutcliffe, lecturer at King's College, to the University readership in botany tenable at that College.

Announcements

MR. E. S. HISCOCKS, secretary of the National Physical Laboratory, has been appointed director of the United Kingdom Scientific Mission in the British Commonwealth Scientific Office in Washington; he will also be attaché for scientific questions to the British Embassy. He will succeed Mr. H. J. Hadow, who has completed his term of office in Washington and will return to duty with the Department of Scientific and Industrial Research in England.

MR. B. W. COLLINS, of the New Zealand Department of Scientific and Industrial Research Geological Survey Office, Christchurch, has been appointed scientific liaison officer in Great Britain, under Dr. V. Armstrong, at the New Zealand Scientific Liaison Office, which is a unit of the British Commonwealth of Nations Scientific Liaison Office, Africa House, Kingsway, London.

THE British Scientific Instrument Research Association's laboratories at South Hill, Chislehurst, Kent, are to hold five open days during October 7–11. Inquiries should be sent to the Director at that address.

THE Society for Water Treatment and Examination is to hold its autumn meeting at the Palace Hotel, Southend-on-Sea, during October 2–4. Further details can be obtained from the Hon. Secretary, 41 Carshalton Road, Sutton, Surrey.

THE Institute of Personnel Management, jointly with the National Institute of Industrial Psychology, has arranged a five-day course in "The Use of Statistics in Personnel Management", to be held at the National Institute of Industrial Psychology, 14 Welbeck Street, London, W.1, during October 28–November 1. Further information can be obtained from the Training Officer, Institute of Personnel Management, Management House, London, E.C.4.

THE Chemical Engineering Group and London Section of the Society of Chemical Industry are to hold a joint symposium on "Safety in Chemical Industry" on October 14 and 15 at the Royal Institution, Albemarle Street, London. Full details and application forms can be obtained from the Assistant Secretary, Society of Chemical Industry, 14 Belgrave Square, London, S.W.1; registration should be completed before October 5.

AN informal symposium on "Column Packings for Gas Chromatography" will take place at the University of Cambridge on October 4. The meeting is being organized by the Gas Chromatography Discussion Group under the auspices of the Hydrocarbon Research Group of the Institute of Petroleum and will commence at 11 a.m. The proceedings will not be published in full. Application for tickets should be made before August 26 to Dr. H. Purnell, Department of Physical Chemistry, Free School Lane, Cambridge.

THE first International Symposium on Gas Chromatography, sponsored by the Analysis Instrumentation Division of the Instrument Society of America, is to be held in the Kellogg Center for Continuing Education, Michigan State University, during August 28–30. The Symposium, under the general chairmanship of H. J. Noebels, is to be held in six sessions devoted to the theory of gas chromatography, the application of gas chromatography instrumentation in the laboratory, analysis of high-boiling materials by gas chromatography, the application of gas chromatographic techniques to the purification of chemicals, and gas chromatography instrumentation for continuous automatic analysis. All inquiries should be addressed to the Conference Registrar, Instrument Society of America, 313 Sixth Avenue, Pittsburgh 22, Pennsylvania. Registration must be complete by August 15.

ERRATUM. Messrs. A. T. Willis and G. Hobbs state that in the communication entitled "A Modified Nagler Medium" in *Nature* of July 13, p. 92, the following correction should be made: par. 3, line 4, for "0·03 per cent neutral red", read ". . . 0·003 per cent neutral red".

BRITISH STEEL CASTINGS RESEARCH ASSOCIATION

NEW RESEARCH STATION

THE new Research Station of the British Steel Castings Research Association in Sheffield was opened on June 4 by Sir Harry Jephcott, chairman of the Council of Scientific and Industrial Research. The Station comprises an experimental foundry, laboratories and offices and is built on a site which is conveniently disposed in relation to the centre of the city and the main-line railway stations. The present buildings, which provide 12,500 sq. ft. of accommodation, occupy somewhat less than half a 2-acre site, leaving plenty of space for future expansion. The total cost of the buildings and equipment has been £93,000 and the Association is now provided with much-improved facilities for experimental work, which has previously been carried out in limited temporary accommodation and in the works of member firms.

The experimental foundry occupies an area of 90 ft. by 40 ft. and is large enough and sufficiently equipped to permit foundry processes to be investigated on a scale reasonably comparable with industrial practice. It is served by a 3-ton overhead-travel crane, operated electrically and controlled from the floor, and provision has been made for all essential foundry operations. Modern sand preparation plant is installed and, in addition to facilities for hand moulding and core making, there is a simultaneous jolt-squeeze moulding machine, a core blower and a shell moulding machine.

The main steel-making furnace is of 6-cwt. capacity and is a graphite resistor rod furnace, basic lined and operating at 225 kilowatts (single phase), a type of melting unit little known in Britain but popular on the Continent. This is suitable for pilot-plant scale steelmaking research. A smaller high-frequency furnace of the spark-gap type, with 30-lb. capacity, is also installed. The provisions for cleaning castings, welding and heat treatment are adequate for the largest size casting which can be made from the steelmaking furnace.

Grouped around the experimental foundry in two single-story bays are the machine shop and laboratories. The machine shop is fully equipped for pattern making and for the construction of special research equipment. The laboratories are devoted to metallurgy, mechanical testing, chemical analysis and the study of sands and refractories. The metallurgical laboratory houses two projection microscopes and two bench microscopes and also contains X-ray diffraction apparatus and a microphotometer. The latter equipment is being applied to a study of foundry dusts as well as to studies of sands and refractories and general metallurgical problems. Provision is also made for thermal analysis, and a dilatometer and equipment for the measurement of the hardenability of steels are under construction. The test house contains a 50-ton tensile testing machine and a combined Izod–Charpy impact machine with ancillaries for testing at sub-zero temperatures. Vickers and Brinell hardness machines and special equipment for the testing of miniature tensile specimens complete the equipment in this section.

The chemical laboratory is equipped for routine chemical analysis including semi-micro methods. Absorptiometric techniques of analysis are in use, and special equipment is provided for flame photometry and for the determination of hydrogen in steel. The sand and refractories laboratory houses equipment for the evaluation and control of foundry moulding materials, including a petrological microscope and a pH meter. Equipment for the differential thermal analysis of clays and the determination of refractoriness of sands, clays and refractories is under construction.

Offices for the research staff and space for storage are provided at one end of the foundry bay. A separate building contains a laboratory which is concerned with problems of industrial health. This work is primarily concerned with the assessment and control of airborne dust in foundries. The laboratory is provided with a dust tunnel in which known dust concentrations simulating foundry atmospheres can be generated and maintained for the calibration and comparison of dust sampling instruments. Provision has also been made for measurements of the efficiency of dust collecting equipment. Portable equipment is also available for a study of noise-levels and for analysis of the frequency distribution of noise.

A further single-story building houses the administrative offices and the library and information section, together with rooms for ciné photography and document copying. The Association makes considerable use of film for the dissemination of the results of its work, and the conference room, which can seat forty, is equipped for film projection.

The staff of the Association now totals forty-nine, of whom eleven are senior graduate investigators. In addition, four bursars are maintained at universities.

The occasion of the opening of the Station was marked by a special luncheon, which was attended by the Lord Mayor of Sheffield, the Master Cutler (Sir Peter Roberts, M.P.) and representatives of the University of Sheffield, the Department of Scientific and Industrial Research and member firms of the Association. In proposing the toast of the Association, Sir Harry Jephcott paid tribute to the design and layout of the Research Station. Mentioning the fact that 80 per cent of the industry were members of the Association, he urged the remaining 20 per cent also to join since, in his view, the work of the Association with its new facilities would undoubtedly make a material contribution to the technical efficiency of its members. He urged the Association to include in its programme an adequate proportion of fundamental research, which was always in the long run the best investment in research. He also stressed the importance of maintaining close contact with the universities and hoped that the Association, now that it had acquired its own laboratories, would not give up its practice of maintaining university bursars.

Replying to the toast, Mr. Kain, chairman of the Council of the Association, traced the origin of the Association, which had taken over the steel foundry work formerly carried on by the now extinct Steel Castings Division of the British Iron and Steel Research Association and the Research and Development Division of the British Steel Founders' Association, and paid tribute to those who had co-operated in its formation. He acknowledged also the assistance which the Association received from the directors and staff of member firms on advisory and other committees. He stressed the need for qualified staff in the industry to apply the results of the Association's work and hoped that the Association would be able to play some part in providing facilities for education and training for nominees of members. Finally, he welcomed the representatives of the City and University of Sheffield.

After the official opening, the Association held a series of open days for the benefit of staff from member firms and others closely associated with the industry. In all, approximately 450 visitors have inspected the Research Station during the first and subsequent open days. A. H. SULLY

BRITISH CAST IRON RESEARCH ASSOCIATION

OPEN DAYS

THE British Cast Iron Research Association, Alvechurch, Birmingham, held two open days on July 3 and 4, the first day being set aside for representatives of member firms, and the second day for visitors from other research associations, Government laboratories, trade associations, universities, technical colleges and institutions.

The new experimental melting station was opened by the president of the Association, Mr. J. J. Sheehan, on July 3. It covers an area of 5,000 sq. ft. and is fully equipped with oil-fired crucible furnaces, a 5-ton S. W. L. electric travelling crane, sand preparation and moulding equipment. In addition, it is furnished with four 'Efco' electric high-frequency melting furnaces of 10, 5, 2 and 1 cwt. capacity. Cupola furnaces, including facilities for both hot-blast and cold-blast melting, will be provided eventually, and will permit melting under both acid and basic conditions in a water-cooled melting zone. The annexe to the station is equipped for rough grinding, shot-blasting, heat-treatment, coremaking, and for carrying out small experimental melts. The equipment here includes a 30-kW. high-frequency vacuum melting furnace made by the National Research Corporation of Cambridge, Massachusetts, with a melting capacity of 30 lb.

Experimental investigations on view included the majority of the work in progress under the current research programme. Several investigations on the soundness of iron castings were illustrated and included the effect of physical variables and composition on the soundness of grey cast iron; solidification sequences in iron castings, and the soundness of nodular iron castings.

Aspects illustrative of the work on malleable cast iron included investigations on 'inverse' greyness in unannealed malleable castings, the influence of graphitization on decarburization, and a study of the nucleation of the melt by counting the eutectic cell size. Factors influencing the chilling tendency of cast iron and work on the solidification mechanism of white cast irons were also exhibited.

An effort is being made to provide data to enable cast iron to be used for steam engineering applications at temperatures above 450° F., the current temperature limit. Growth tests are being carried out up to 600° C. and the battery of creep testing machines recently installed will permit creep tests to be made on materials evaluated on the basis of these growth tests. Further work on mechanical properties refers to the correlation of composition and structure of high-phosphorus materials, based on the eutectic cell size concept. Other investigations under this heading include a scrutiny of the form of the stress/strain curve for grey cast irons; the influence of testing conditions and composition on the properties of pearlitic nodular cast irons; the influence of arsenic and phosphorus on the high-temperature tensile properties of these materials, and the influence of understressing on their properties in the normalized state.

A display was shown to illustrate the corrosion-resistance of ordinary and high-alloy cast irons in various media. Other work in this field covers the application of cathodic protection to prevent severe pitting attack in cast iron propellers, and the mechanism of the corrosion attack on cast iron diesel engine waterways in the presence of antifreeze solutions.

A recent project undertaken by the Association concerns an attempt to utilize low-phosphorus native ores by providing means of dephosphorization, and work shown included experiments with the oxygen top-blowing process. Equipment is available for the determination of gaseous elements in cast iron, using vacuum fusion and vacuum heating techniques. Certain of these elements are of significance in the study of pin-holing of iron castings, in the origination of enamelling defects, and in the graphitization of malleable cast iron. An investigation is in progress on the causes of the premature failure of ingot moulds, in association with the manufacturers of ingot moulds and bottom plates.

Current research on foundry moulding and core sands includes high-temperature testing, using a high-frequency oscillator to determine load/deformation characteristics at high temperatures; the testing and properties of CO_2 process sand moulds and the properties of bonded sand in the green state.

Routine methods of examination and analysis were demonstrated in the chemical and spectrographic laboratories, and in the sands, metallographic and mechanical testing laboratories. Work was also exhibited to illustrate some of the investigations undertaken by the Development Department which, of course, is chiefly concerned with giving advice to member firms on the numerous technical problems that arise in the course of production.

Experimental work on the occurrence of sub-surface blow-holes in association with manganese sulphide segregations was shown, and work on dry sliding and lubricated wear at high and low local pressures. A further exhibit gave the results of an investigation into the failure of certain heavy section castings due to abnormal forms of graphite, associated with the presence of traces of such elements as lead, tellurium, selenium and bismuth.

The work of the Foundry Atmospheres Section was illustrated by a display showing the pattern of formation, dispersal and control of dust in the foundry, together with dust sampling equipment. Some of the equipment developed for local dust control was also shown and included external dust control arrangements for pedestal grinders, a wet spray collar for bars used in de-coring difficult castings, a ventilated wire handbrush and wet spray type of grit and dust arrester for cupola furnaces.

Finally, some of the work based on the experience of the operational research team, which visits foundries by invitation and provides advice on problems of production and layout, was shown, and included recommended suitable foundry layouts, improvements in production flow lines, the correct use of patterns and moulding equipment, and data on output and costs.

J. G. Pearce

ORGANIZATION OF THE METEOROLOGICAL OFFICE

In a written answer in the House of Commons on June 28, the Secretary of State for Air, Mr. G. Ward, said that the Committee appointed in 1955 under Lord Brabazon to review the organization of the Meteorological Office in relation to current and future requirements saw no reason to question the wisdom of the decision to entrust responsibility for the State meteorological service to the Air Ministry, and was satisfied that the close association of the Meteorological Office with aviation since 1919 had been mutually advantageous. The Committee considered that the present standing of the Meteorological Office as a scientific institution was high, and that users had great confidence in the services provided. The Committee welcomed the work being done by the research staff in the development of numerical methods of forecasting, and the decision to install an electronic computer at the Central Forecasting Office. It considered that greater precision in local forecasting might be achieved by more detailed study of local weather characteristics, coupled with the use of radar scanners. The development of a combined headquarters at Bracknell should eliminate the present loss of effort due to dispersal of the Office.

As a result of the Committee's recommendations, the Meteorological Office had been reorganized under a director-general with two sections, concerned with forecasting and services and with research, each under a chief scientific officer, and a third section, under an assistant secretary, with administration and general duties. Measures approved as a result of the report, including an increased number of higher level posts, and an increase in the number of senior appointments open to the experimental officer class, would improve the prospects available to both the experimental and the scientific officer classes. The Committee expressed the hope that it would be possible to bring home to the universities the challenge which meteorology presented to the imagination of the first-class physicist or mathematician.

The Committee suggested no changes in the constitution or terms of reference of the Meteorological Research Committee or in the division of the research programme between the Meteorological Office and the universities, but recommended that the arrangement under which a separate grant is made to the Royal Society for fundamental research should be reviewed at the end of the current five-year period and that grants for research emanating from the Air Ministry should thereafter normally be channelled through the Meteorological Research Committee. This recommendation was still under discussion. The Committee also recommended a system of research grants for postgraduate study in meteorology, and the Department of Scientific and Industrial Research was willing to consider awards under the scheme it administers.

The Committee also recommended a review of the man-power requirements for aviation services. The requirements of civil aviation were being reviewed in conjunction with the Ministry of Transport and Civil Aviation. Local forecasting units were desirable for other purposes, particularly in agricultural and horticultural districts, but a more detailed examination was required before any pattern of development could be approved. The Minister said that he had accepted the Committee's recommendation that the existing Meteorological Committee should be replaced by an advisory committee of not more than five members, all of whom would be outside the Government service. The new Committee would consist of an independent chairman, and four members, including the chairman of the Meteorological Research Committee *ex-officio* and another scientist, appointed after consultation with the president of the Royal Society, and normally two laymen. Lord Hurcombe had accepted the invitation to become chairman of the new Committee, which would be required to keep under review the progress and efficiency of the Meteorological Office and the broad lines of its current and future policy, the general scale of effort and expenditure devoted to the Meteorological Office, and the contacts between the Office and those using its services.

WATER RESOURCES OF GREAT BRITAIN

The publication of the Surface Water Year Book 1954–55[*] is a further welcome addition to the growing body of hydrological knowledge for Great Britain. The first four Surface Water volumes dealt with the periods 1935–36, 1936–37, 1937–45 and 1945–53: since that date the volume has been appearing annually and the time-lag in publication has been steadily reduced.

There has been an increase from 102 gauging stations in 1953–54 to 116 gauging stations in this latest volume; but some changes have been made in the presentation of the statistics for 1954–55 in order to reduce both the size and the cost of the volume. The daily mean discharge tables have been omitted, while hydrometric records of 'reservoired areas' have been summarized on a single page. The station descriptions have been rearranged and condensed, and the surface geology particulars omitted. Complete records and details are, however, available for consultation at the Surface Water Survey Centre.

While progress is thus being made in the collection and dissemination of these basic hydrological data concern is still being expressed at the lack of a much-needed water policy for Great Britain. A notable debate in the House of Lords on May 29 surveyed the steadily increasing consumption of water per day, and also the rising consumption of water per head per day throughout the country. Emphasis was laid upon the very great and continuing increase in the industrial use of water over the past two decades, to which must be added the demand likely to arise in agriculture with the application of summer irrigation methods. Some areas now face the prospect of permanent water shortages even under normal conditions, while a slight drought will rapidly exhaust available reserves and bring industry and agriculture to a standstill in other localities.

---

[*] Ministry of Housing and Local Government, and Scottish Office. The Surface Water Year-Book of Great Britain 1954–55. (Hydrometric statistics for British Rivers, together with related rainfalls, for the year ended 30th September, 1955.) Pp. xi+64. (London: H.M.S.O., 1957.) 15*s*. net.

Replying for the Government, Lord Mancroft stated that the subcommittees appointed by the Central Advisory Water Committee of the Ministry of Housing and Local Government in 1955 would be pressed to complete their investigations as a matter of urgency. The Government hoped for a reduction in the large number of water undertakings in the country (nearly 1,300) by voluntary amalgamations. It was also studying the whole question of the organization of hydrological research, as one of the chief difficulties in the present situation was the lack of reliable information. No authoritative figures of the rate of increase of water consumption, nor of the available total resources, existed. It was fully realized that not enough information was yet available to assess accurately exactly how serious the problem was likely to be, but "Her Majesty's Government are most earnestly and objectively going into this whole problem" as the urgent need for a more precise assessment of the situation had been recognized.

THE WELLCOME TRUST

REPORT FOR 1937–56

THE first report of the Wellcome Trust, recently issued*, covers the first twenty years of the Trust's activities, during 1937–56. Its major interest is in the general survey of the origin and activities of the Trust, which occupies the greater part of the report, including an appreciation of the work of the founder, the late Sir Henry S. Wellcome. There are a classified list of grants and a clear statement of the policy pursued by the trustees, with appended lists of recipients of various medals and prizes awarded by or on behalf of the Trust, and of publications from the Wellcome Trust Research Laboratories or subsidized by the Trust. During the period the trustees have made grants totalling £313,883 for medical research, museums and libraries, and have allocated £64,053 to assist research in the history of medicine. £48,335 has been spent on completing Sir Henry Wellcome's "Archæological Enterprises", and on publishing the findings of these and a related independent study, while £4,105 has been provided for Wellcome medals and prizes. To August 31, 1956, a total of £739,788 had been provided for medical and veterinary research, of which £300,000 was allocated in respect of building and other projects not yet effective. Of this sum, £193,090 was for research chairs, £321,700 for building, adaptation and equipment of research laboratories, £52,215 for special equipment, and £7,699 for miscellaneous travel grants.

For reasons given in the report the trustees had to postpone for more than ten years the full development of the main activities of the Trust, and in the meantime they recognized that the archæological enterprises which Sir Henry Wellcome had been supporting at Jebel Moya and other sites in the Sudan, and at Tell ed-Duweir (Lachish) in Palestine, had prior claim. The results of the former work at Jebel Moya were published for the trustees by the Oxford University Press in 1949, and those of the explorations at the neighbouring sites of Abu Geili, Segadi and Dar el Mek in a later volume; while after excavation at Lachish was terminated by the outbreak of war in 1939, the results were prepared for publication by Miss O. Tufnell.

At an early stage, however, the trustees considered the choice of areas of research in medicine and related sciences in which they could plan to use the funds at their disposal to serve the objects of the Trust: the advancement of research bearing on medicine, surgery, pharmacy and allied subjects, and the establishment, endowment and maintenance of research museums or libraries in that field. They took the view that these funds would be used to the best advantage if not too widely diffused, and if their activities were planned so as to be complementary to those of other funds with similar aims. Accordingly, they decided to give preference to those subjects which had attracted Sir Henry Wellcome's own active interest and so to give priority to work in pharmacy and pharmacology, veterinary medicine and tropical medicine. While continuing to provide funds for the several medals and prizes established by Sir Henry himself, it is not a part of the trustees' present policy to consider the creation of other such awards.

In 1938, the trustees accepted full responsibility for the laboratory at Thessaloniki, where Dr. H. Foy had been engaged on research in malaria, and the laboratory was named the Wellcome Trust Research Laboratory, Thessaloniki. In 1953, the appointment of Dr. Foy was given academic permanence. Later, the laboratory was extended, and when continuation of the work at Thessaloniki became impossible at the end of 1940, the work was transferred to the South African Institute of Medical Research, Johannesburg, until work could be resumed at Thessaloniki in 1945–48. With the reduction of the prevalence of malaria to very small proportions in consequence of the insecticides discovered during the War, it was again decided to close the Thessaloniki laboratory, and since 1949 Dr. Foy and his co-workers have been working, with Nairobi as base, on a programme now including the study of nutritional and other forms of anæmia widely prevalent in the tropics, as well as the distribution of the sickle-cell trait. In 1942, the trustees made a grant of £20,000 for further research on the development of methods for drying human blood-plasma and serum and for the purchase of the necessary plant, and between February 1943, when the plant came into operation, and September 1945, when it closed down, this plant provided stable dried plasma and serum to meet the whole of the requirements of the Royal Navy and of the civilian population of Britain, and a proportion of those of the Army and of the Royal Air Force.

A grant of £44,000 was made in 1945 for the creation of the Wellcome professorship of clinical tropical medicine in the London School of Hygiene and Tropical Medicine, and one of £74,000 in 1946 for the endowment of a full-time Wellcome professorship of pharmacology in the School of Pharmacy, University of London. Grants of £18,000 were made to the Animal Health Trust and of upwards of £10,000 to the Pharmaceutical Society for research fellowships, and £15,000 was awarded for various research fellowships in such subjects as biochemistry—while in 1956 a Wellcome research professorship of anæsthesiology was established at McGill University with a total grant of about £50,000; together with a Wellcome associate research professorship at the University of Pennsylvania, with a grant of about £25,000.

SURFACE ACTIVITY

THE Second International Congress of Surface Activity was held in the Senate House of the University of London during April 8–13. The enthusiasm shown by participants emphasized that the popularity of this subject in both the scientific and industrial interests throughout the world had in no way diminished since the First International Congress, held in Paris in 1954. Since the United Kingdom had the largest foreign contingent to the First International Congress, the International Union of Pure and Applied Chemistry asked the United Kingdom to undertake to arrange a second congress.

The late Dr. L. H. Lampitt, the British representative on the International Union of Pure and Applied Chemistry, and also the vice-president and honorary treasurer, gathered together a meeting of British scientists, both academic and industrial, who might be interested in the subject. This meeting elected an *ad hoc* committee under the chairmanship of Dr. Lampitt to proceed with the organization of a congress along the lines of the First International Congress in Paris. This committee decided that the subject-matter of the Second International Congress should be extended to include other aspects of surface activity than those discussed at the first world meeting, which was mainly on detergency. The Comité Français de la Détergence sponsored and organized the First International Congress. It arranged the first programme on industrial lines, in so far as the subject-matter was chosen from the industrial applications of surface chemistry rather than from the basic science. Moreover, the subjects were subdivided into seventeen divisions, which were run concurrently, necessitating a serious overlap of interests.

This the *ad hoc* committee for the Second International Congress now decided to change. The organizing committee accepted a programme drawn up with a scientific bias, with contributors both from academic and industrial research laboratories throughout the world. The contributors were asked to place their work under sections derived from surface activity taking place at specific interfaces, such as gas–liquid interface, liquid–liquid interface, solid–liquid interface, solid–gas interface and cell–water interface. Furthermore, to avoid overlap of interests, the sessions were to be run concurrently in only two lecture theatres, and the programme was so chosen that, so far as possible, sessions on allied subjects would not clash.

It was originally hoped to have approximately one hundred contributions, which it was thought possible to discuss in two lecture theatres over four days; but such was the world enthusiasm for this subject that more than two hundred contributions had already been received by the closing date, and late contributions were more than sufficient to start a Third International Congress. It was considered, after much hesitancy, that the two hundred papers should be accepted and that they should be run approximately twenty-five a day for the four days, in each of the two lecture theatres. It was decided that contributions should be pre-published and pre-circulated throughout the world to participants, so that the papers could be taken as read at the Congress meeting. It was considered that by this method two hundred papers could be fully discussed.

It was estimated that approximately one thousand people would attend such a meeting, which restricted the choice of venue to the Senate House of the University of London, where two large lecture theatres, the William Beveridge Hall and the Institute of Education, each seating more than five hundred, are available. It turned out that approximately one thousand people paid to come to the Congress, and since both lecture theatres were consistently full (sometimes over-full) throughout each of the four days of the meeting, it would appear that many more attended.

The contributions were sent in from nineteen countries, and were fairly evenly distributed throughout the world. Apart from the United Kingdom, which contributed eighty-three papers, they included the following countries, with the number of papers in brackets:

United States (32)
U.S.S.R. (21)
France (9)
Germany (8)
Holland (8)
Japan (8)
Australia (7)
Belgium (6)
Canada (5)
Italy (3)
Finland (2)
Israel (2)
Poland (2)
India (1)
Kenya (1)
Sweden (1)
Switzerland (1)
Yugoslavia (1)

The programme was arranged in the two lecture theatres *A* and *B* in the following sections:

A		*B*	
First day			
Gas/Liquid and Liquid/Liquid Interface (32)		Solid/Gas Interface (39)	
Insoluble films	14	Physical adsorption	26
Soluble films	7	Chemisorption	13
Foams	4		
Evaporation retardation	3		
Monolayers liquid/liquid interface	4		
Second day			
Gas/Liquid and Liquid/Liquid Interface (24)		Solid/Gas Interface	
Solubilization and micelles	13	Chemisorption (continued)	
Emulsions	7		
General phenomena	4	Electrical phenomena (15)	
Third day			
Solid/Liquid Interface (22)		Solid/Liquid Interface (28)	
Washing	14		
Suspensions and agglomerations	8	Contact angles, spreading and wetting	10
		Flotation	18
Fourth day			
Cell/Water Interface (Biological) (13)		Solid/Liquid Interface (25)	
		Flotation (continued)	
		Adhesion	6
		Adsorption	9
		Lubrication	5
		Nucleation	5
Total 91		Total 107	

The long-suffering publishers of the proceedings of the Congress have arranged to print the discussion in four volumes: Vol. 1 to include gas/liquid and liquid/liquid interfaces; Vol. 2 to include washing, suspensions and agglomerations and cell/water interface; Vol. 3 to include solid/gas interface, physical adsorption and chemisorption; and Vol. 4 for solid/liquid interface, including electrical phenomena. It was considered that dividing the interests in four volumes, offering reasonable economic units for those interested in selected topics, was preferable to publishing the whole proceedings of the meeting in a more expensive single unit. The written discussion of the transactions at the meeting has been found to be unexpectedly voluminous, but the proceedings of the Congress should appear in the near future, while world interest is focused on modern surface activity.

The entire proceedings should give a very useful up-to-date version of modern surface chemistry in all its aspects, both pure and applied, and will take several years to digest.

The discussion at the Congress seemed to specialize in classical surface chemistry at the air/liquid and liquid/liquid interfaces, such as thermodynamics of adsorption at interfaces and micelles, evaporation retardation, transport of material across liquid/liquid interfaces, formation of emulsions, the meaning of contact angles at the solid/gas/liquid line interface, long-range forces at solid surfaces and nucleation phenomena. It was truly astonishing to listen to the thermodynamic specialists expressing opposing views, with complete confidence that the opposing side was wrong and that they were fundamentally correct. It was somewhat horrifying to notice that the thermodynamic concepts and terms were frequently misused. For example, Harkins free energy term was repeatedly misquoted as a Gibbs free energy term, and systems used by Hill, Guggenheim, Harkins and Everett freely intermixed. It seems essential that some common system with defined symbols should be established once and for all.

There was relatively little discussion on the solid/gas interface, presumably since there were very high-geared participants in the audience which possibly frightened off discussion, and unfortunately the chairmen were conscientious and ruthless about being on time with their programme. But there were some very interesting papers in this section, especially those dealing with perturbation effects of the adsorbing molecules on solid surfaces, and also of the solid surface on the adsorbing gas molecules. This was shown experimentally by infra-red adsorption of the molecules in the adsorbed phase. This work has immediate application to studies in catalysis and possible means of measuring changes in bulk properties of solids by changes in surface phenomena. There were some interesting papers, partly in review, on the surface energies of solids in relation to their chemistry, which has interesting possibilities for future work in this intriguing field.

Some workers in the solid/liquid interfacial field related all the occurring phenomena to the inherent roughness of the solid surfaces. Others seemed to have such smooth surfaces that they could measure attractive forces between solid surfaces at molecular distances apart. Each party was completely unconvinced by the arguments of the opposing side.

One of the applied subjects which aroused interest was the use of long-chain hydrocarbon alcohols in the form of condensed monolayers in retarding the evaporation of water. On the laboratory scale this is successful up to 90 per cent; on field trials on areas of about an acre the efficiency is about 30–40 per cent, using alcohols spread from floats containing solid beads of the material. Hope was given that by using liquid spreaders in which the long-chain alcohol is soluble, the film could be spread and held on areas of square miles. Since water evaporates in Australia at the rate of about six million tons a year per square mile, the economic stimulus to this type of work is most pronounced. Papers dealing with the role of water molecules selectively adsorbing at crystal surfaces, either soluble in saturated water solutions or insoluble in the form of powders in the atmosphere, have very interesting practical implications: in the first case for the selective flotation of soluble salts, and in the second case for nucleation in cloud seeding experiments, where copper sulphide is shown to be the best seeding agent, and zinc sulphide, for example, one of the worst.

The meeting presented a great opportunity for scientists of the Western world to listen to and to learn the methods of the Russian and Polish scientists, expressed mainly in English. This was invaluable, since the Russians are more active in the field of surface chemistry than their Western colleagues, and their papers with references present a good record of their recent research.

From the enthusiasm shown by those producing original manuscripts and by participants at the discussion, there should be no difficulty for the organizers of the next International Congress to start thinking soon on a programme for the third world meeting.

J. H. SCHULMAN

STUDIES ON FERTILITY

THE seventh annual conference of the Society for the Study of Fertility was held in Exeter on July 5 and 6. As in the past, papers were read on clinical, basic scientific and veterinary subjects covering the field of fertility in its broadest sense.

From the Liverpool School, already well known for its contributions to testicular and male accessory-organ anatomy and physiology, came two further papers. E. J. Clegg studied changes in the coagulating glands and seminal vesicles in rats by killing litter mates at weekly intervals. He found the former to be histologically more labile than the latter and, since there was no simple relation between age, testicular histology and the fructose content of the coagulating gland, concluded that fructose content was not a reliable indicator of hormone production. In discussion, it was pointed out by T. Mann that the fructose content of the secretions, rather than of the gland cells, was likely to be of more significance, while J. Macleod drew a parallel with Leydig cell secretion rather than numbers as of importance from the point of view of testis hormone production. E. W. Macmillan, also from Liverpool, has continued his studies on sperm transport through the epididymis of the rat. Since ipsilateral orchidectomy after the introduction of radio-opaque medium into the vasa efferentia does not affect the time of passage through the vas deferens, it is concluded that the *vis a tergo* from the testis is of no importance. The rate was similarly unaffected by ligation of the terminal efferential tubule or by high ligation of the ductus epididymidis. Trypan blue particles are transported in the same way as radio-opaque media.

A symposium on the methods of testing for spermicidal activity was opened by T. Mann (Cambridge), who pointed out that no single biochemical mechanism was affected by all spermicides, and that there were at least three groups of these: enzyme and competitive inhibitors, sulphydryl-binding substances, and surface-active agents. Clare Harvey (Exeter) discussed the dichotomy of opinion on whether the end-point for tests should be the concentration required to kill within a fixed time, or the time required to kill at a fixed concentration. She preferred the former (modified Baker test of total spermicidal activity). B. Carruthers (London) said that at the Family Planning Association Laboratories, satisfactory results had been obtained with the modified Baker test. He also mentioned his studies with the Davidson contact test and how the results could be affected by various factors, especially ingredients in the vehicle themselves not regarded as spermicides. P. E. Lindahl (Sweden) described how he has replaced the upper and lower glass surfaces of the cell used in the Davidson test by semi-permeable membranes, permitting the access of oxygen, since he believes conditions within the vagina to be aerobic, not anaerobic. J. Macleod (New York) said that a special laboratory has been set up at the Sanger Bureau of the International Planned Parenthood Federation, with the express purpose of investigating all the existing methods of spermicidal testing. He himself believed that fundamental studies on spermigration are urgently needed.

There were two papers on the effects on pregnancy of certain antimetabolites and nucleotoxic compounds. J. M. Robson and D. Jackson (London) considered three groups of substances—spindle poisons, such as podophyllotoxin, colchicine and demecolcine; mitotic poisons, such as chlorambucil and nitrogen mustards; and antimetabolites, such as 6-mercaptopurine and furazolidone. Most of these were effective in interrupting pregnancy, some even before the stage of implantation; but, in general, the therapeutic ratio was too low for them to have any practical value. Of those agents which were effective before implantation, the antimetabolites seemed most promising. J. Yudkin, B. P. Wiesner and Miriam Wolfe had found β-peltatin less active, but with a higher therapeutic ratio than podophyllotoxin. α-Peltatin was more active and less toxic than β-peltatin. Two doses, given on successive days, were more effective than a single dose. Demecolcine was very effective, but the escaped litters after marginal doses showed many congenital abnormalities and the surviving offspring had impaired fertility. It was promising for future research that slight changes in chemical structure markedly influenced both effectiveness and toxicity.

M. G. Scott and Patricia P. Scott (London) have made detailed studies of the effects on the reproductive organs of cats of chronic infections, dietary inadequacies and ligation of the pancreatic duct. These all led to retardation of development and regression of the gonads and accessories. In the testes abnormal cell types were seen, while poor follicular activity was found in the ovaries. It was concluded that the primary effect in all cases was malnutrition rather than a direct influence of the chronic infection, and that it was exerted on the anterior pituitary body, the gonadal changes being secondary.

Hilda M. Bruce (London) said that all the hamsters at present in the western hemisphere were descendants of a single litter found at Aleppo twenty-five years ago. About twelve varieties were now recognized. Of these, the ruby-eyed fawn mutant showed genetic sterility in the male. Her investigations on this revealed that fertility is confined to a period of 2–3 weeks after puberty, the subsequent progressive infertility being due to increasing defect of spermatogenesis. The testicular histology showed disorganization of isolated tubules even in young and still fertile animals; this process progressed with advancing age so that by 150 days sterility was complete. Multinucleate cells (similar to those found by Scott and Scott in their subnormal cats) appeared. In the ensuing discussion, T. Mann pointed out that copper-containing enzymes are implicated in both pigment formation and spermatogenesis, suggesting a possible enzyme defect as the basis for the genetic sterility.

Delphine M. V. Parrott (London) described a technique for orthotopic ovarian grafting which avoided the difficulties of surgical removal of the ovaries in the recipient mouse, by subjecting the animals to 900 r. of whole-body irradiation, followed by the injection of bone marrow from other mice. A later modification was to give two successive doses of 450 r. since, although the effect on the ovary is cumulative, the systemic effects of a given dose (if not lethal) are relatively short-lived. Orthotopic grafts made four weeks after irradiation proved fertile, but if grafting were delayed until nine weeks after irradiation, fertility was reduced, perhaps because of the reduced blood supply to the very atrophic ovarian remnant.

J. L. Hancock (Cambridge) has made an examination of cleaved ova recovered after natural or artificial insemination of sows in order to assess the fertilization-rates. He found 90·5 per cent cleavage after natural matings, but only 21·7–47·8 per cent after artificial insemination. The highest rates with the latter were obtained when undiluted semen or semen diluted with egg-yolk glucose phosphate diluent was used (46·2 and 47·8 per cent cleavage). When semen diluted as above but stored for twenty-four hours at 5° C. was used, the rate was only 21·7 per cent, and when semen diluted with seminal plasma was inseminated the rate was 22·2 per cent. It was also observed that the number of spermatozoa in the zona pellucida of recovered eggs was in general considerably lower after artificial insemination than after natural mating. There seems little doubt that the efficiency of artificial insemination compares unfavourably with that of natural mating.

G. I. M. SWYER

AGRICULTURE AT CAMBRIDGE

A COLLECTION of eleven review articles which have prefaced the Memoirs of the School of Agriculture, Cambridge, over the past few years has recently been published as the first volume of "Agricultural Research and Teaching at Cambridge"*. As Sir Frank Engledow points out in a foreword it is always profitable to ponder objectives and achievements of the past in deciding courses for the future, and these articles review in some detail the researches and achievements by members of the staff of the School of Agriculture in particular fields. A historical review of researches in the physiology of reproduction is made by F. H. A. Marshall in which he traces the development of this subject from the founding of a university lectureship in agricultural physiology in 1908. Kenneth Smith summarizes twenty years of virus research, and G. D. H. Bell describes how the application of genetical principles to the breeding of agricultural plants was the inspiration for the establishment of the Plant Breeding Institute in 1912. The researches in animal nutrition are reviewed by E. T. Halnan. The Horticultural Research Station was opened in 1922, and R. M. Woodman describes the changes in the character of the work which have taken place since then. The study of agricultural economics commenced as early as 1896 with the endowment of a lectureship in this subject by Sir Walter Gilbey, and the late A. W. Menzies-Kitchen traces its development up to 1951. H. H. Nicholson describes the evolution of field drainage investigations which commenced in 1930 at the suggestion of Sir Frank Engledow. J. Hammond gives an account of animal production research, including the breeding experiments of Punnett which led to the establishment of the Poultry Research Station. The history of Cambridge University Farm, from the leasing of Burgoynes Farm between 1900 and 1910 and its establishment on the present site, is related by W. S. Mansfield, the director. F. Hanley details the development of crop husbandry experiments from 1894 onwards. The final review is by Sir Frank Engledow, who describes the changes in agricultural teaching at Cambridge between 1894 and 1955.

These collected reviews give a very complete picture of the progress in agricultural research at Cambridge from the end of the past century, when it was considered doubtful whether it was proper for the University to raise agriculture to the status of a Department with a chair, to the present time, when the importance of agriculture in the national economy alone is ample justification for sound teaching and research.

NIGHT-VISION EFFICIENCY

During the Second World War the practical need arose of selecting military personnel for tasks requiring high visual performance at night, and various tests of 'night-vision efficiency' were therefore devised. The Medical Research Council initiated a study of these tests, and has recently published a report* of its findings. The report consists largely of experimental work and makes the following positive contribution to this difficult topic: absolute thresholds vary from individual to individual, and the amount of light an individual requires to perform an acuity discrimination (detecting the orientation of a Landolt *C*) and a more complex perceptual task (identifying objects in a dimly lit Hogarth print) is strongly correlated with his absolute threshold, provided that these tests are such that rods, not cones, are operative.

Minor technical criticisms can be made; for example, the frequency of positive responses to 'blank' stimuli is not reported, though this is an important index of the subject's reliability, and the figure must have been used in making the 'guessing correction' when the thresholds were determined by the procedure described in an appendix (a war-time report by H. K. Hartline and P. R. McDonald for the United States Committee on Aviation Medicine). The absolute threshold seems to be more variable than many other visual functions, such as optimum acuity, critical fusion frequency and differential threshold; it would be interesting to know why this is so, but the authors offer no experiments which throw more light on the matter. Nor have they made a serious attempt to assess the relative importance of this particular factor compared with the many other factors (for example, variations in pupil size, residual refractive error, night myopia, avoidance of foveal fixation, pattern of eye movements, reliability of response, intelligence, motivation, etc.), which may also be important in causing variations in visual performance at low illuminations. Nevertheless, a positive, well-established result is valuable in a field full of conflicting claims, and the experiments on acuity at low illuminations will interest visual physiologists.

STATISTICAL ANALYSIS OF A RANDOM, MOVING SURFACE

A theoretical study, by Dr. M. S. Longuet-Higgins, of the statistical properties of a surface the elevation of which is given by the superposition of a large number of simple harmonic waves with random phases travelling in different directions has recently been published under the title "The Statistical Analysis of a Random, Moving Surface"*. At time t, the elevation (measured from the mean level) at a point in the surface the co-ordinates of which are (x,y) is taken to be

$$\zeta(x,y,t) = \sum_n c_n \cos(u_n x + v_n y + \sigma_n t + \varepsilon_n)$$

where the phases ε_n are distributed independently and uniformly over the interval $(0,2\pi)$, and the angular frequency

$$\sigma_n = \sigma(u_n,v_n) = \sigma(\sqrt{u_n^2 + v_n^2})$$

the function σ depending on the type of wave motion and the medium in which it takes place. In the limit as $n \rightarrow \infty$, ζ becomes a two-dimensional stationary normal stochastic process, the properties of which are completely determined by the spectral density of energy $E(u,v)$, defined by

$$\sum_{\substack{u_n \leqslant u \\ v_n \leqslant v}} \tfrac{1}{2}c_n^2 = \int_{-\infty}^{u} \mathrm{d}u' \int_{-\infty}^{v} \mathrm{d}v' E(u',v') \, ;$$

the correlation function of the process is the cosine transform

$$\int_{-\infty}^{\infty} \mathrm{d}u \int_{-\infty}^{\infty} \mathrm{d}v \, E(u,v) \cos(ux + vy + \sigma(u,v)t)$$

This has recently been used as a model for surface waves in the open ocean; the author suggests that it may also be applicable to other geophysical phenomena such as microseisms or perturbations of the ionosphere.

The main part of the study is concerned with the use of the limiting representation to derive the following properties: (1) the probability distribution of ζ and the components of slope ζ_x, ζ_y at any point; (2) the average number of zeros of ζ per unit distance along a line in an arbitrary direction in the x–y plane; (3) the average length of surface contours per unit area and the distribution of their direction; (4) the average densities of maxima, minima and 'specular' points (points where ζ_x, ζ_y take given values) per unit area; (5) the probability distribution of the velocities of zeros of ζ along a given line; (6) the probability distribution of the velocities of contours and 'specular' points; (7) the probability distribution of the amplitude and phase of the wave envelope, defined as

$$\sum_n c_n \exp i\{(u_n - \bar{u})x + (v_n - \bar{v})y + (\sigma_n - \bar{\sigma})t + \epsilon_n\}$$

where $\bar{u}, \bar{v}, \bar{\sigma}$ are the mean values of u, v, σ with respect to the spectral distribution $E(u,v)$. All the results are expressed in terms of quantities which are functions of the moments

$$m_{pq} = \int_{-\infty}^{\infty} du \int_{-\infty}^{\infty} dv\, u^p v^q E(u,v)$$

of the spectral distribution. Special attention is paid to the case of a narrow spectrum, for which $E(u,v)$ is only appreciable when u and v lie in narrow ranges, so that the waves are approximately uniform in wave-length and direction. This situation might occur with ocean waves arising from a single distant storm area during a not too long time interval. A result of Rice ("The Mathematical Analysis of Random Noise", *Bell System Technical Journal*, 46; 1945) relating to the wave envelope of a one-dimensional process can then be used to obtain an approximation to the distribution of the heights of maxima and minima of ζ.

The problem of estimating $E(u,v)$ from observational data is also considered. A method of approximating to $E(u,v)$ given the values of a finite number of moments of the energy distribution for the intersection of the surface with an arbitrary vertical plane is developed. It is shown that these moments are determined by the average numbers of zeros of ζ and its derivatives per unit distance along an arbitrary straight line, and by the mean velocities of these zeros, and hence may be estimated if values of ζ and $\partial\zeta/\partial t$ along the line are available. In the case of the sea surface it is suggested that these might be recorded by radar in an aircraft flying on a fixed course at high speed and constant altitude. No information is given about the accuracy of estimates of $E(u,v)$ made by this method. Some knowledge of the way in which the accuracy increases with the area covered by the observations for typical spectral distributions would be useful, although it might be difficult to obtain this theoretically.

VARIABLE STARS IN THE MAGELLANIC CLOUDS

IN a recent paper on the spectra of some variable stars in the Magellanic Clouds (*Mon. Not. Roy. Astro. Soc.*, 116, 5; 1956), M. W. Feast, of the Radcliffe Observatory, Pretoria, gives the results of a study of spectra obtained with the $f/2$ camera of the 2-prism spectrograph (86 A./mm. at Hγ) at the Cassegrain focus of the 74-in. Radcliffe reflector. Four variables in the Small Cloud and six in the Large Cloud were selected (another star turned out to be a galactic, foreground object) and the results are tabulated in order of increasing period. Individual velocities are not published at present, but the average velocity of stars in the Small Cloud was 133 km./sec. and in the Large Cloud 274 km./sec.; the other star, *HV* 2882, had a low velocity. The Magellanic Cloud variables appear to be normal late *F* and early *G* type supergiants, and no abnormalities were noticed nor were any emission lines found to indicate that they are Population ii (*W* Virginis) cepheids. The results are important because the work of Gascoigne and Kron (*Aust. J. Sci.*, *Supp.*, 17, 23; 1954; and *Pub. Astro. Soc. Pacific*, 65, 32; 1953) led to the suggestion that the Cloud variables were in fact Population ii cepheids.

The variable *W* Men. was discovered by Luyten (see *Harvard Bulletin*, 846; 1927) and lies in the direction of the Large Magellanic Cloud. It is an *R* CrB.-type variable, and if it is a member of the Large Magellanic Cloud it is the only star of the class known in an extragalactic system, and the only one with a known distance and absolute magnitude. Spectroscopic criteria are the only means at present for determining the absolute magnitude of this class of variable. Owing to the faintness of the star, it was necessary to use a short trail to obtain a spectrum with the $f/2$ camera, and two spectra obtained on December 1, 1953, and February 10, 1954, were sufficiently good for certain definite conclusions to be reached. Its radial velocity is about 260 km./sec., which is in good agreement with the expected velocity for a cloud member in this position. While the spectral type is necessarily uncertain, it appears to be a supergiant of type *F*5–*G*0, most probably *F*8 with Hγ weak for the class. It may be concluded that the supergiant characteristics shown by the *R* CrB. variables are really indicators of high luminosity in these stars. Using a modulus of 19·2 mag. for the clouds, given in a paper on the distances of the Magellanic Clouds by Thackeray and Wesselink in *The Observatory* (75, 33; 1955), an absolute magnitude at maximum for *W* Men. of − 5·4 is deduced.

POLLEN IN TERRESTRIAL SOILS

G. W. DIMBLEBY (*New Phytol.*, 56, 12; 1957) has pointed out that pollen analysis of terrestrial soils, as opposed to aquatic deposits, has received surprisingly little attention, especially when it is apparent that much pollen must fall on dry ground just as it does on bog surface. The assumptions that pollen falling on soils is rapidly destroyed, or removed by downwash, or so mixed and dispersed as to be valueless in studies of vegetational history, are not necessarily well founded. In fact, he has found that pollen may be present in terrestrial soils in numbers considerably exceeding those of many peat deposits. The highest frequencies, nearly 1·5 million per gm. oven-dry soil, were recorded in mineral layers, though raw humus also gave high counts. The preservation of pollen is not satisfactory in soils of which the pH is above 5, but in acid soils it appears to be independent both of soil type and texture. The soil pollen content is markedly reduced by fire, and this may account for the relatively low pollen frequencies in the mineral layers of some heath soils. Acid tropical soils may contain considerable quantities of pollen, and this, together with the high values in temperate soils, suggests that the normal aerobic microbiological processes of acid soils are not so destructive of pollen as might be thought.

The distribution curve of each species of pollen through the profile assumes a characteristic form according to the length of time the pollen has been in the soil, owing to the gradual downward movement under the influence of percolating water. This movement is normally a very slow process. From the distribution patterns it is possible to outline the broad features of past vegetation changes, but interpretation is always comparative, and independent time fixes must be obtained for absolute dating.

CONGENITAL PORPHYRIA IN BOVINES: FIRST LIVING CASES IN BRITAIN

By PROF. E. C. AMOROSO, F.R.S.
Royal Veterinary College, London, N.W.1

R. M. LOOSMORE

AND

PROF. C. RIMINGTON, F.R.S., and B. E. TOOTH
University College Hospital Medical School, London, W.C.1

HUMAN congenital porphyria is a rare disease, only some thirty-five undoubted cases having been reported[1]. In animals, the condition was unknown until 1936, when it was discovered in a herd of cattle in Swaziland. The clinical and biochemical features were fully described by Fourie[2] and Rimington[3] and resembled closely the findings in human cases. Eventually further unrelated bovine cases were discovered in South Africa (Fourie and Rimington[4]; Fourie[5]), and later Clare and Stephens[6] reported the condition in pigs in New Zealand. Jórgensen and With[7] have more recently reported its occurrence in both pigs and bovines in Denmark. We have now observed living cases of congenital porphyria in England. Two of these have been demonstrated to the Physiological Society (Amoroso, Loosmore, Rimington and Tooth[8]).

Although the literature contains several reports of dark-coloured bones in abattoir material (see Fourie[5]) and Ross[9] has conducted a post-mortem examination upon what was almost certainly a case in the Birmingham district, these occurrences are the only ones of which we have certain knowledge. Mr. B. L. Nestel, veterinary officer in the Department of Agriculture, Jamaica, has informed one of us (C. R.) privately that in 1956 he saw in Jamaica three calves born with pink teeth and sensitive to sunlight, but unfortunately an exact diagnosis was not made while the animals were alive. Further cases of bovine congenital porphyria may, however, be occurring in a herd of Jamaica Black cattle.

Description of Cases: In July 1956, one of us (R. M. L.) was asked to see a two-year-old roan Shorthorn heifer (*A*) on a farm in Buckinghamshire. The animal had purplish-red teeth and, on being turned out in the spring for the first time, had developed on the rump and shoulders crusty sores suggestive of photosensitization. The diagnosis of congenital porphyria was confirmed a few days later as a result of further clinical and biochemical investigations; the urine and faeces were rich in porphyrins (see Table 1). From the farmer's records it was clear that he must have had two other cases in closely related heifers (*B* and *C*) born in 1951 and 1954 respectively, but the condition had not been recognized as congenital porphyria at the time. The breeding of all these animals is shown in Fig. 1. Two months after this first living case was seen, inspection of the herd revealed two more cases among the young calves. One (*D*) was a full sister of the two-year-old just described; the other (*E*) had a normal twin (*F*), and all three animals were bought for further study. Their breeding is set forth in Fig. 1. Calves *D* and *E* both have discoloured teeth and pass a pinkish urine rich in porphyrins (Table 1). The fluorescence of the teeth in ultra-violet light is fiery red, while fluorocytes are visible in the peripheral blood and are numerous in the bone marrow; blood plasma shows red fluorescence. The twin *F* shows none of these features.

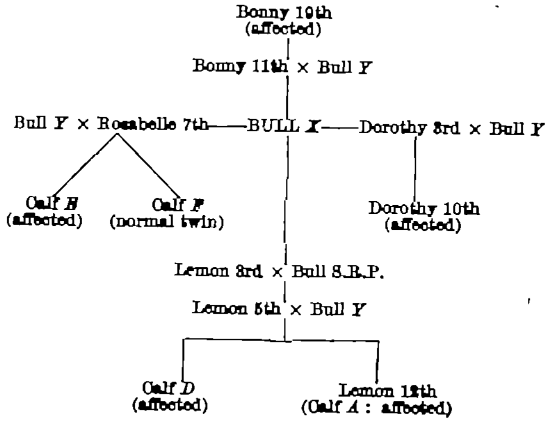

Fig. 1. Inheritance of congenital porphyria in a Shorthorn herd. Bulls *X* and *Y* must be carriers of the recessive character

Biochemical Investigations: Quantitative determinations of porphyrins in the excreta are recorded in Table 1, the control animals being the twin *F* and an unrelated calf (*G*) of approximately the same age. Paper chromatography of the isolated porphyrins (Falk and Benson[10]; Falk, Dresel, Benson and Knight[11]) established the preponderance of series I isomers. Porphobilinogen was absent from the urine and from a liver biopsy specimen, confirming that the

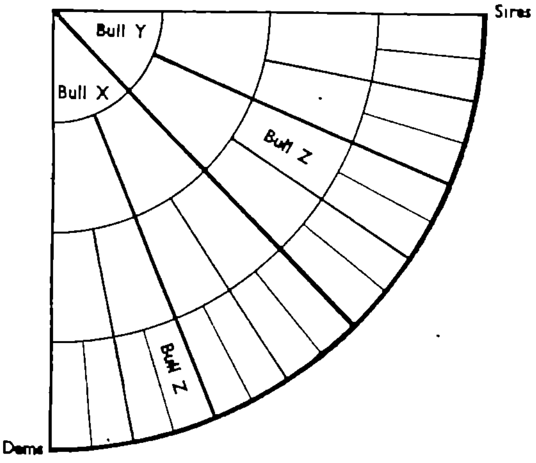

Fig. 2. Breeding of bulls *X* and *Y* showing, on the maternal side, common ancestry in bull *Z*

disturbance of porphyrin metabolism was of the 'hæmopoietic' type[12].

Hæmolysates of avian erythrocytes are known to be capable of synthesizing hæm and porphyrins *in vitro* from added glycine[13]. Human erythrocytes, although incapable of utilizing glycine, can carry the synthesis from added porphobilinogen or δ-aminolævulic acid as far as the coproporphyrin stage (Rimington[14]), and both the uroporphyrin and coproporphyrin formed belong exclusively to the series III isomers. Normal calf blood was found to behave similarly; but when a hæmolysate, prepared from the mixed bloods of the affected animals *D* and *E*, was incubated with porphobilinogen, the uroporphyrin formed consisted of isomers I and III in about equal amounts. One of us (C. R.) has observed similar production of series I porphyrins *in vitro* from bloods of two different human cases of congenital porphyria. It is clear that the enzymic abnormality in this disease persists in the mature circulating erythrocytes and is not confined to early stages of maturation in the bone marrow.

Genetics: The herd in which these cases have occurred is one of pedigree Shorthorns and their inheritance has been relatively easy to trace. The farmer obtained bull *X* from a well-known breeder and used him on the farm for several years; he appeared in every way normal. A second bull *Y* was then obtained from the same breeder, and all the cases have occurred in crosses between *Y* and daughters of *X* (Fig. 1). In the South African material, bovine congenital porphyria was shown to be inherited as a recessive Mendelian character (Fourie[3]), and if a similar mode of inheritance were to be operating in the present instance both bulls *X* and *Y* would be carriers of the recessive gene. An examination of the stock books, kindly carried out for us by Prof. N. J. Scorgie and Mr. John David, revealed that *X* and *Y* had a common ancestor on the maternal side, the bull *Z* in Fig. 2, a circumstance which greatly strengthens the presumption that the bulls *X* and *Y* were clinically normal carriers of the recessive gene for congenital porphyria. How far the condition may be disseminated in pedigree dairy Shorthorn stock we do not know, but it would seem highly probable that further cases in such cattle will be encountered and possibly with increasing frequency.

DIFFERENCE AND DERIVATIVE SPECTRA

By Dr. A. E. MARTIN

Sir Howard Grubb, Parsons and Co., Ltd., Optical Works, Walkergate, Newcastle upon Tyne 6

During the past few years both difference (sometimes called differential)[1] and derivative spectra[2] have been employed to bring out details of the spectra of minor components in the presence of a strong absorption background due to basic material.

In the first method, the background absorption is cancelled out by using a double-beam spectrometer, with sample in one beam and in the reference beam a substance with closely matching background absorption but free from the minor constituent.

In the derivative method the basic absorption is eliminated to a large extent by differentiating either once or twice the d.c. output signal from the spectrometer. The effect of single and double differentiation on a typical absorption band is shown in Fig. 1, and it will be seen that the second derivative much more closely resembles the original band than does the first derivative. If a small band $A_1 = f(\nu)$, where A_1 is the absorbance and ν the frequency, is superimposed on a background represented by $A_2 = a + b\nu + c\nu^2$, a, b and c being constants, the total absorbance $A = A_1 + A_2$ and $\frac{d^2A}{d\nu^2} = 2c + f''(\nu)$, so that the effect of the background absorption disappears except for a constant displacement.

Single differentiation is effected simply by applying the signal voltage $f(\nu)$ to a capacitor C_1 in series with a resistor R_1. If the scanning rate is constant so that $d\nu/dt = r$, it is found that the voltage appearing across R_1 is

$$rR_1C_1f'(\nu) - r^2R_1^2C_1^2f''(\nu) + \dots$$

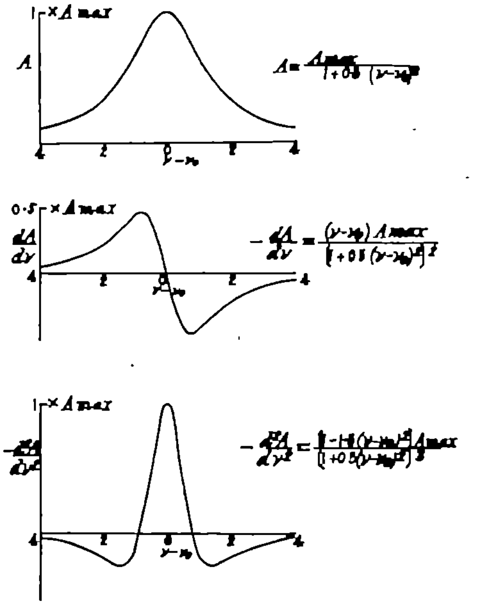

Fig. 1

To obtain a satisfactory result, rR_1C_1 must be reduced sufficiently to make the second term acceptably small.

It is the purpose of the present communication to suggest a simple means for obtaining the second derivative. The desired result is obtained by using the circuit shown in Fig. 2, and it can be shown that the voltage across R_2 is

$$r^2Pf''(\nu) - r^3PQf'''(\nu) + r^4P(Q^2 - P)f''''(\nu) - \ldots$$

where $P = R_1R_2C_1C_2$ and $Q = R_1C_1 + R_1C_2 + R_2C_2$.

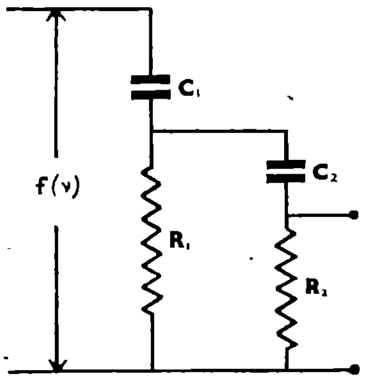

Fig. 2

For an absorption band of the general type shown in Fig. 1, $f''(\nu)_{\text{max.}} = -\frac{8Pr^2}{w^2} f(\nu)_{\text{max.}}$, where w is the half-width, that is, the frequency difference corresponding to points where $f(\nu) = \frac{1}{2}f(\nu)_{\text{max.}}$ To make the third derivative small compared with the second, rQ must be kept low, while for a given value of Q, P should be as large as possible and approach the maximum value $\frac{Q^2R_2}{4(R_1 + R_2)}$. Q should be as large as is convenient, and since R_1 and R_2 are limited by the characteristics of the spectrometer amplifier and recorder used, C_1 and C_2 must be large. Practical values are $R_1 = 2,000\ \Omega$, $R_2 = 500\ \Omega$ and $C_1 = C_2 = 100\ \mu$F., leading to $P = 0{\cdot}01$ and $Q = 0{\cdot}45$.

If the voltage across R_2 is applied to a self-balancing potentiometer which gives full scale for 1 mV. and the maximum signal from the spectrometer amplifier, $f(\nu)_{\text{max.}}$, is 5 volts, $8Pr^2/w^2 = 1/5,000$, and since $P = 0{\cdot}01$, $r/w = 1/20$. Thus for a band with a half-width of 10 cm.$^{-1}$, $r = 0{\cdot}5$ cm.$^{-1}$ per sec. In these conditions $r^4P(Q^2 - P)f''''(\nu)/r^2 Pf''(\nu) = 0{\cdot}023$, which is reasonably small. Even better results are obtained if R_2 may be increased beyond 500 ohms. For given values of P, R_1 and R_2, the best result is obtained when $C_2(R_1 + R_2) = R_1C_1$.

Returning to difference spectra, if in a double-beam spectrometer the incident energy at frequency ν is I in both beams, and if α represents the fraction of this radiation transmitted by the basic material while β is the fraction transmitted by the minor component, the double-beam servo system will operate to equalize the energy in the two paths so that the indicated value will be $\alpha\beta I/\alpha I = \beta$, which is the quantity required. If, however, there is a frequency shift h between the reference and sample spectra, $\alpha_1 = f(\nu)$ for the reference cell and $\alpha_2 = f(\nu + h)$ for the sample. The quantity measured, therefore, is $\beta\alpha_2/\alpha_1 = \beta f(\nu + h)/f(\nu)$. Making use of Taylor's theorem and ignoring terms higher than the second, the measured value is $\beta[1 + hf'(\nu)/f(\nu)]$ instead of β. This effect is clearly demonstrated in Fig. 3, which shows the superimposed spectra of ethylbenzene (top curve), polystyrene foil (middle curve) and finally the difference spectrum with ethylbenzene in the

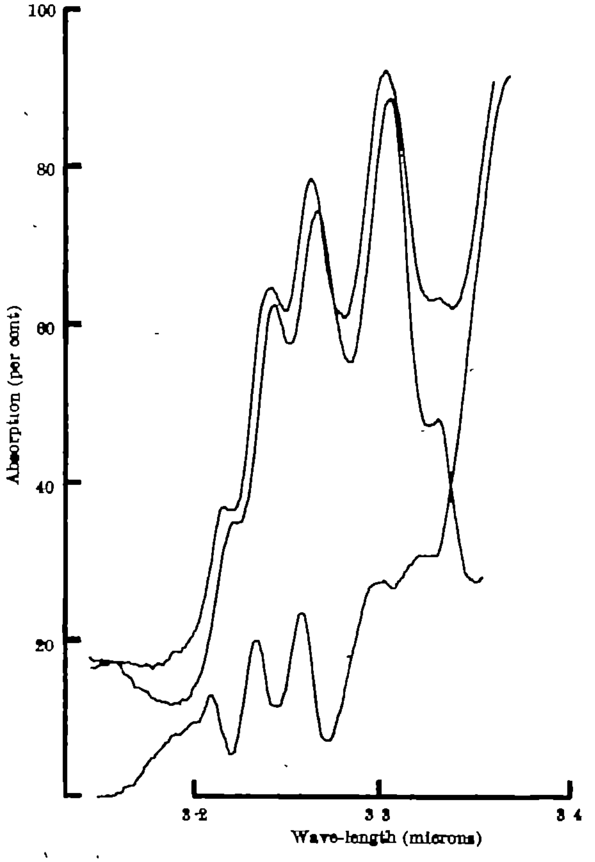

Fig. 3

sample beam and polystyrene in the comparison beam. The bands chosen (aromatic C—H) are similar in shape and intensity but differ slightly in frequency; β can be taken as approximately equal to unity in this case.

It should be possible to use this effect to measure accurately small frequency-shifts due to variation with temperature and concentration, and in addition to study the effect of changing from one solvent to another. This procedure can also be used to prove the identity of two samples of the same compound or to establish the difference between closely allied substances.

If the spectrometer records absorbance rather than transmittance, the result is presented even more directly. Let A_1 be the absorbance of the reference material ($= f(\nu)$) and A_2 the absorbance of the sample ($= af(\nu + h) + \bar{f}(\nu)$), where $af(\nu + h)$ is contributed by the basic material and $\bar{f}(\nu)$ is due to the minor constituent, if present; h denotes a frequency-shift between a band in the reference and sample materials, and a allows for possible error in matching. I_1 and I_2 denote the radiation transmitted by reference and sample, respectively, and since the double-beam balancing system weakens the reference beam until equality is reached with the sample beam, the required attenuation is I_2/I_1 and the quantity recorded is $\log I_1 - \log I_2 = A_2 - A_1 = af(\nu + h) + \bar{f}(\nu) - f(\nu) = (a - 1)f(\nu) + ahf'(\nu) + \bar{f}(\nu) = hf'(\nu) + \bar{f}(\nu)$ when $a = 1$. From the record h can be determined.

AN EFFECT OF *p*H ON THE UPTAKE OF SALT BY PLANT CELLS

By R. G. HURD* and DR. J. F. SUTCLIFFE

Department of Botany, King's College, University of London

A NUMBER of investigators have examined the effect of *p*H value of the medium on uptake of salts by plants[1-4]. In most cases little, if any, influence has been observed over a range of *p*H values from 5 to 9. A major difficulty in the interpretation of such experiments is that buffered solutions must be employed if relatively constant *p*H values are to be maintained, and these give rise to spurious effects either by interference with the entering salt, or by influences upon metabolism which indirectly affect absorption. Such effects can be minimized by use of a buffer system, which does not contain easily absorbable ions, and is metabolically inactive. This article presents the results of some experiments to determine the effect of *p*H on the absorption of salts by parenchyma cells of various storage organs, using such a buffer system (*tris*-hydroxymethylaminomethane + sulphuric acid).

In an experiment with red beet root tissue, it was found that the rate of absorption of potassium ions from a 0·0024 *M* solution of potassium chloride was much greater at *p*H 8·5 than at *p*H 6 (Fig. 1). The rate of uptake of chloride, however, was approximately the same at the two *p*H values. Consequently, whereas the rate of absorption of chloride was only slightly lower than that of potassium at *p*H 6, considerably more potassium ions than chloride were absorbed at *p*H 8·5. The buffer components of the medium were essentially inactive in this experiment since, as Fig. 1 shows, the uptake of salt from an unbuffered control solution, with a *p*H value of about 6, was approximately the same as that from the buffered solution at *p*H 6. Evidence is also available, although it is not presented here, showing that the buffer probably did not interfere significantly with the uptake of salt from the alkaline solution.

When the experimental period was extended beyond 72 hr., it was observed that potassium absorption from the alkaline solution continued to exceed the uptake of chloride until the tissue became saturated with salt. When both tissues were saturated, the total amount of potassium in the disks at *p*H 8·5 was approximately twice that held by the disks in the acid solution.

The magnitude of these effects on both the relative uptake of the two ions, and the amounts of salt held in the tissue at saturation, varied somewhat with the concentration of salt in the medium. No stimulation of potassium uptake at the alkaline *p*H from a solution of 0·024 *M* potassium chloride was observed until about 12 hr. after absorption commenced. Afterwards, uptake at *p*H 8·5 exceeded that at *p*H 6, and the amount of potassium held by the tissue at saturation was greater in the former solution. How-

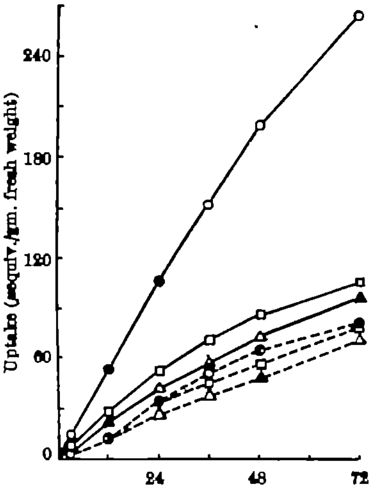

Fig. 1. Amounts of K^+ and Cl^- absorbed by washed beet slices at 18° C. from 0·0024 *M* potassium chloride solutions at *p*H 6. ☐, Buffered; △, unbuffered; and at *p*H 8·5, ○, buffered. Full line refers to potassium, pecked line to chloride

ever, the effects were, in each case, smaller than those observed in experiments with salt solutions at a lower concentration. This was attributable mainly to a greater effect of increased concentration in promoting the uptake of both potassium and chloride ions at *p*H 6 than at *p*H 8·5. The amount of salt held by the tissue at saturation was unaffected by concentration at *p*H 8·5, but more potassium and chloride ions were present in tissue kept at *p*H 6 in 0·024 *M* potassium chloride than in 0·0024 *M* potassium chloride (Table 1).

---

* Present address: W.A.C.R.I., Tafo, Ghana.

Table 1. Amounts of K^+ and Cl^- (μequiv./gm. fresh wt.) held by red beet root disks at saturation from solutions of 0·0024 *M* potassium chloride and 0·024 *M* potassium chloride at *p*H 6 and *p*H 8·5 (temperature = 18° C.). Results are means of several experiments

Concentration	Ion	*p*H 6	*p*H 8·5
0·0024 *M*	K^+	160	293
	Cl^-	83	82
0·024 *M*	K^+	196	294
	Cl^-	116	86

The degree of stimulation of cation absorption induced at the alkaline *p*H also varied between different kinds of tissues. The greatest stimulation was obtained with phloem tissue from parsnip roots; white beet root tissue, artichoke tuber tissue and carrot tissue (phloem and xylem parenchyma) showed effects similar in magnitude to those obtained with red beet. A significant effect was also obtained on intact barley seedlings. On the other hand, the rate of absorption of potassium by slices of potato tuber tissue and swede hypocotyl tissue (outer xylem) was the same at *p*H 8·5 as it was at *p*H 6.

It has been found that the effects of *p*H observed in these experiments were related to the presence of bicarbonate ions in the alkaline solutions, and to the ability of some tissues to absorb these ions. Over a part of the *p*H range examined, the amount of potassium ions taken up in 6 hr. at 25° C. by red beet tissue increased proportionately with the retentivity of carbon dioxide as bicarbonate ions in the solutions (Fig. 2). At the highest *p*H values (8–9), however, it is evident that some factor other than the amount of bicarbonate ions in the solution becomes limiting. The observed correlation indicates that the excess absorption of potassium over chloride ions at *p*H 8·5 may be associated with uptake of bicarbonate ions, and it was thought that the more rapid absorption of potassium ions from solutions containing bicarbonate as well as chloride may be responsible for the *p*H effect. Table 2 shows that the uptake of potassium by red beet and parsnip tissue proceeded more rapidly from a solution of potassium bicarbonate, or from a solution containing both potassium chloride and potassium bicarbonate, than from a solution of potassium *chloride, when all* the solutions had initially the same potassium content. Swede tissue, on the other hand, absorbed potassium less rapidly from a potassium bicarbonate solution than from a solution containing potassium chloride.

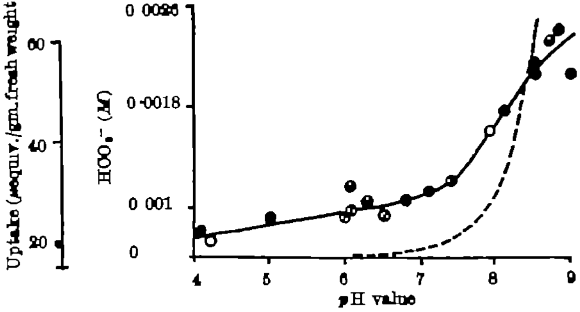

Fig. 2. Uptake of potassium ions by washed beet slices in 6 hr. at 25° C. from 0·0024 *M* potassium chloride solutions at different *p*H values (full line); and the (theoretical) amounts of HCO_3^- retained in solution under the same conditions (pecked line)

Table 2. Amounts of K^+ (μequiv./gm. fresh wt.) taken up in 21 hr. by various tissues at 25° C. from unbuffered solutions of (*a*) 0·0024 *M* potassium chloride; (*b*) 0·0024 *M* potassium bicarbonate; and (*c*) 0·0012 *M* potassium bicarbonate + 0·0012 *M* potassium chloride

Tissue	*a*	*b*	*c*
Red beet	30·0	41·5	44·0
Parsnip	29·0	85·5	81·0
Swede	88·0	67·5	81·5

In this experiment the solutions were not buffered, and did not have exactly the same initial *p*H value, so that *p*H could have been directly influencing the result. However, the uptake of potassium from potassium bicarbonate solutions reduced to *p*H 6 with sulphuric acid was found to be greater than that from potassium chloride solutions buffered at the same *p*H. It is therefore concluded that the presence of bicarbonate ions was the important factor promoting the uptake of potassium from alkaline solutions.

This experiment demonstrated that potassium uptake is stimulated by the presence of bicarbonate ions in tissues capable of showing a *p*H effect; this does not necessarily mean that bicarbonate ions are absorbed, although uptake is strongly indicated. It is well established that bicarbonate is not accumulated as such by plant cells[5] and it is sometimes implied that they are not even absorbed[6]. Some fixation of bicarbonate ions by excised barley roots was, however demonstrated by Overstreet *et al.*[7] using carbon-11-labelled bicarbonate. More recently, Kadry[8] has claimed that there is a marked accumulation of carbon derived from bicarbonate in several plants. We have found, using carbon-14-labelled bicarbonate, that bicarbonate ions are taken up by beet disks in equivalent amounts to the sodium ions absorbed from a sodium bicarbonate solution (Table 3).

Table 3. Amounts of Na^+ and HCO_3^- (μequiv./gm. fresh wt.) taken up by red beet disks in 6 hr. at 18° C. from 0·0012 *M* $NaH^{14}CO_3$ solutions after pretreatment for 1 hr. in unlabelled 0·0012 *M* sodium bicarbonate. Uptakes of HCO_3^- based on radioactivity measurements on (*a*) the external medium; (*b*) the tissue

Replicates	Na^+	HCO_3^- (*a*)	HCO_3^- (*b*)
Exp. *A* 1	8·3	7·0	9·0
2	7·0	6·5	5·5
Exp. *B* 1	4·5	4·5	5·0

Other tissues, including swede and potato, will take up bicarbonate ions from solutions of potassium or sodium bicarbonate, but whereas those tissues capable of showing a *p*H effect will absorb bicarbonate also in the presence of chloride, those not showing the *p*H effect will not readily absorb bicarbonate when chloride is present if the two are supplied in equimolar amounts (Fig. 3). This latter observation may account for the absence of a *p*H effect in potato and swede tissues.

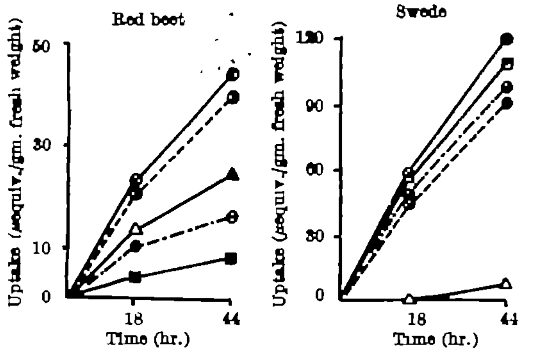

Fig. 3. Uptake of ions by red beet root tissue, and swede hypocotyl tissue, at 18° C. from unbuffered solutions of 0·0024 *M* KCl (○—.—○, K^+ uptake); 0·0024 *M* $KHCO_3$ (○— —⊙, K^+ uptake); and 0·0012 KCl + 0·0012 *M* $KHCO_3$ (○——○, K^+ uptake; ▲——▲, HCO_3^- uptake; ⊟——⊟, Cl^- uptake)

When bicarbonate ions are absorbed, few, if any, remain as such in the tissue. We have shown by paper chromatography that most of the bicarbonate is converted in beet tissue into various organic acids, particularly malic acid.

It may be concluded, therefore, that the apparently unequal uptake of cations and anions observed with some tissues from solutions of potassium chloride at *p*H 8·5 is in reality an equal uptake of positively and negatively charged particles. The sum of chloride and bicarbonate ions absorbed in a given time is equivalent to the amount of potassium ions taken up. This is possibly also the case with the same tissues at *p*H 6, and, since fewer bicarbonate ions are available in acid solutions, the smaller difference between the rate of potassium and chloride uptake is understandable (Fig. 1).

The conclusion that cations are absorbed in association with bicarbonate ions is of interest in another connexion. Ulrich[9] observed that when an excess uptake of cations over anions occurs in barley roots (for example, when absorption takes place from a solution of potassium sulphate), there is an increase in the organic acid content of the tissue. Ulrich looked upon this as a device to maintain electrical neutrality following unequal uptake of oppositely charged particles. Lundegårdh[10], on the other hand, believed that synthesis of organic acid anions was the cause rather than the effect of an excess absorption of cations. In terms of the hypothesis outlined above, under the particular conditions in which apparent unequal uptake occurred in the present experiments, bicarbonate ions are absorbed in association with some of the potassium ions taken up, and are converted into organic acid anions which serve to maintain electrical neutrality within the tissue. An accumulation of bicarbonate ions in the tissue could presumably accomplish the same end, but apparently this does not occur for reasons which are unknown.

It seems unlikely that the concomitant absorption of bicarbonate ions can account entirely for all cases of apparent excess cation uptake observed in plants. In acid solutions, where negligible amounts of bicarbonate ions are presumably present, an excess absorption of cations may occur from certain salts such as potassium sulphate[9]. In these circumstances it seems probable that organic acid anions appearing within the tissue are derived mainly, not from absorbed bicarbonate, but from carbon dioxide. The uptake of carbon dioxide by roots and its fixation as organic acids has been demonstrated by Poel[11] and Jacobson[12]. Jacobson noted a qualitative relationship between the amount of carbon dioxide fixed and the excess cations accumulated by excised barley roots from solutions of various salts. When organic acids are derived from carbon dioxide, the excess cations presumably enter in exchange for hydrogen ions produced by dissociation of the organic acid molecules synthesized. Carbon dioxide fixation cannot account for the observations made in the present experiment, because the greatest effects were found in alkaline solutions which did not contain more dissolved carbon dioxide than did the acid media.

Finally may be considered the less common situation in which an excess of anions over cations is absorbed. Hoagland and Broyer[13] observed a qualitative lowering of the organic acid content of barley roots placed in solutions of calcium bromide, and subsequent workers[8,14] have confirmed this effect. In every case the decrease in amount of organic acid was small, and it is possible that these anions were lost in exchange for the excess bromide absorbed. A more likely explanation seems to be that exchange occurred between internal bicarbonate and external bromide ions. The carboxylating reaction by which bicarbonate is converted to organic acids is likely to be reversible, and will have a definite equilibrium constant. If external anions exchange with bicarbonate ions present in the cell, organic acids will break down to renew the equilibrium. In cases of excess anion uptake by storage tissues, it has been observed that bicarbonate ions appear in the medium in equivalent amounts to the excess anions accumulated[15]. Thus it may be concluded that the examples of unequal uptake of anions and cations by plant cells are likely to be more apparent than real. The concomitant uptake or loss of bicarbonate ions (or carbon dioxide) is likely to be responsible for changes in the organic acid content of the tissue during apparent unequal uptake. No influence of *p*H as such on anion accumulation was detected in any of the tissues examined. This observation makes it unlikely that a mechanism of the type $A^- + ROH \rightleftharpoons RA + OH^-$ as visualized by Jacobson, Overstreet, King and Handley[16] operates in the absorption of anions by these cells.

A full account of this work will be published elsewhere. Our thanks are due to Prof. T. A. Bennet-Clark for his interest in the investigation, and to the Department of Scientific and Industrial Research for providing a maintenance grant to one of us (R. G. H.).

A New Type of Nitrogen-fixing Bacterium

In the course of an investigation in the Jute Agricultural Research Institute on nitrogen transformation in soils cropped with jute, a nitrogen-fixing bacterium has been isolated by the dilution-plate technique. It shows certain morphological and physiological differences from the known non-symbiotic nitrogen-fixing organisms like *Pseudomonas azotocolligans* and those belonging to the Azotobacteriaceae[1]. The cells at first have a coccus-like appearance and occur singly (measuring 0·75–1·0 × 1·5–2·5μ on an average) or as doublets or triplets, gradually changing to rod shape (Fig. 1). The cells are Gram-negative; they contain fat and are very difficult to suspend in water. The optimum temperature for growth was found to be about 28° C. The organism is aerobic, but can be grown under low oxygen tension in Winogradsky's nitrogen-free glucose–phosphate media. It can grow in acidic media also; even at pH 4·0 growth was obtained. Bromo-cresol purple milk (skimmed) is turned alkaline and a sediment is formed at the bottom with a clear liquid surface after ten days incubation at 30° C.

Colonies on Ashby's nitrogen-deficient agar are raised, and are usually oval with mean diameters of 4·6 × 3·3 mm.; but some, especially of the larger colonies, may be pulvinate. At first the colonies are transparent with a yellow tinge, but in three or four days they turn chocolate brown and finally become gelatinous. On Winogradsky's glucose peptone agar, colonies appear earlier but grow more slowly than on Ashby's agar. On the former medium the colonies, when young, have chocolate centres and white shiny edges but gradually become grey or colourless. On potato dextrose agar slants, chocolate-brown colonies develop within two days. The pigment does not diffuse into the medium and is insoluble in water and in alcohol. But under low oxygen tension, the colonies appear somewhat like water-drops without any pigment.

The nitrogen fixed in Ashby's nitrogen-free agar–mannitol medium, when estimated by semi-micro-kjeldahl distillation, was found to be nearly 17 mgm. per gm. of mannitol added, and 253 mgm. per 100 gm. of dried medium after incubation for a period of nine days under optimum conditions.

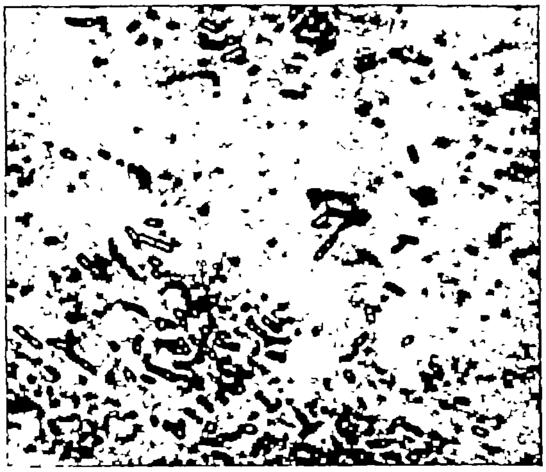

Fig. 1. A new nitrogen-fixing bacterium. × 1,500

Unlike *Azotobacter*, the organism grows in nutrient broth and turns it turbid with a slight yellowish tinge. In nitrogen-free liquid medium, it makes pellicular growth at first and afterwards bulbous gelatinous growth with brown colour; the entire liquid medium becomes jelly-like in about a month. This jelly-like mass, unlike *Pseudomonas azotocolligans*, sticks neither to the side of the flask nor to calcium carbonate at the bottom. If pigmentation does not occur within a week, due to unfavourable growth conditions, no pigmentation develops even on prolonged keeping.

The organism utilizes carbohydrates, especially glucose and mannitol. It has been found that whatever be the source of the energy material, practically no growth is obtained with inorganic nitrogen compounds (either ammonium or nitrates). Further work is in progress.

An Albino Strain of the Desert Locust

During extensive laboratory breeding of the desert locust *Schistocerca gregaria* (Forskål), at the Chemical Defence Experimental Establishment, Porton, twelve albino hoppers (nymphs), creamy-white in colour, occurred among the normal heavily pigmented ones. Six were males and six females, and from them an albino strain has been established in the laboratory of the Anti-Locust Research Centre.

The coloration of normal *Schistocerca* hoppers reared in crowds (phase *gregaria*) consists of a heavy black pattern on a white or yellow ground, while that of young adults is predominantly pink. The pink changes to yellow or straw as the adults become sexually mature. Hoppers of the albino strain reared in crowds, however, do not develop the black pattern, and the adults are almost uniformly ivory-white, becoming yellow on maturation. Goodwin[1] showed that the black pattern of normal *Schistocerca* is due to melanin and the pink colour to insectorubin, and suggested that these two pigments are metabolically interrelated. This suggestion appears to be supported by the apparent absence of melanin from the albino hoppers, although a small amount of insectorubin is present (Goodwin, personal communication).

Schistocerca hoppers reared in isolation (phase *solitaria*) are typically green with little or no black pattern, and they contain neither melanin nor insectorubin[1]. Albino hoppers similarly reared also develop this green colour, without black pattern. Thus, under conditions of isolation, hoppers of the normal and albino strains are indistinguishable.

Nickerson[2] suggested that phase coloration in *Schistocerca gregaria* is controlled by two hormones, one controlling the extent of the black pattern and the other controlling the background colour. He was unable to discover whether these two hormones were separate in their mode of action or whether they formed parts of an integrated system which resulted in the visible coloration. Evidence from the albino strain shows that, despite the absence of black pattern, the background colour shows the same phase changes as in the normal strain. This supports the two-hormone hypothesis and appears to indicate that the two factors can be separated. It is hoped that the albino strain can be used for clarifying further the physiology of phase coloration; living material would be willingly supplied to research workers who may be interested.

The albino strain has now been bred to the F_7 generation without the appearance of any individuals of the normal type and without any loss of vigour. Crosses between albino and normal adults show a Mendelian pattern of inheritance, in which albinism is recessive.

I wish to thank Mr. R. D. MacCuaig for his kindness in sending me the twelve original albino hoppers.

Sclerotization and Melanization: Two Independent Processes in the Cuticle of the Desert Locust

CONSIDERABLE advances in our knowledge of sclerotin formation in the insect integument have been accompanied by little progress in our understanding of melanin formation. This seems to be due to confusion between the two processes of sclerotization and melanization.

The cuticle of the last nymphal instar of the desert locust, *Schistocerca gregaria* (Forskål), is pale and not amber-coloured, although, like that of the cockroach *Periplaneta*[1], it appears to be phenolically tanned. It contains melanin only in well-defined patches. A critical study of melanin formation in this cuticle has led to two important conclusions. First, melanization and sclerotization are two independent processes, as was suggested by Goodwin[2]. Each appears to involve its own copper-protein phenolase. Secondly, the two processes are consecutive in the melanized areas, sclerotization being delayed until melanin formation has been completed. Hitherto it does not seem to have been unequivocally shown that darkening of an insect exoskeleton may not be accompanied by tanning.

In the soft cuticle newly exposed on moulting, a copper-protein phenolase occupies the entire thickness of the presumptive exocuticle (*A*, Fig. 1). This enzyme appears to be identical with that responsible for hardening in the cockroach ootheca[3], in the puparium of *Sarcophaga*[4] and in the cuticle of *Periplaneta*[1]. That it is indeed concerned with hardening is indicated by its absence from the arthrodial membranes, which remain soft throughout the instar. A similar, but more highly reactive, phenolase (*B*, Fig. 1) occupies only those regions of the exocuticle in which melanin is destined to be formed. Attempts to distinguish critically between the two enzymes have been only partly successful. Both activate the same substrates, but differ in the intensity of their action and in the extent to which they are inhibited by the usual phenolase inhibitors.

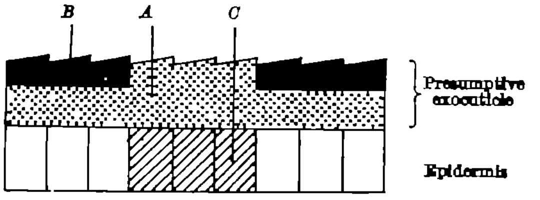

Fig. 1. Normal nymph

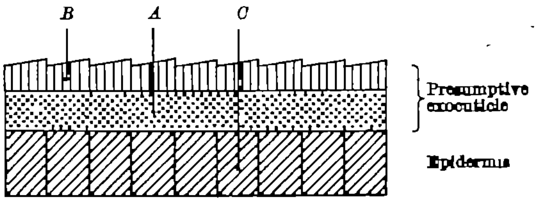

Fig. 2. Albino nymph

Closely correlated with this difference in enzyme activity is the distribution of phenolic material in the epidermis at the onset of the hardening process. In unpigmented areas, strongly reducing material (*C*, Fig. 1) accumulates in the epidermal cells and may represent diphenolic compounds. In pigmented areas, on the other hand, no such material is apparent in the epidermal cells. It is remarkable that the cuticle, at the same developmental stage, is itself slightly argentaffin only in the unpigmented areas. Elsewhere it is not argentaffin, but becomes so after melanin formation has been completed.

The reason why melanin is not formed in the cuticle of the albino strain of the same species of locust[6] may now be referred to. Surprisingly, the highly active phenolase concerned in melanin formation is not lacking (*B*, Fig. 2), but is uniformly distributed throughout the outer zone of the presumptive exocuticle. Nor are diphenols absent from the cuticle, for I have extracted from the exuviæ of albino nymphs the same diphenols (including protocatechuic acid and dihydroxyphenylacetic acid) as from the cuticles of the normal strain. But reducing substances accumulate at the onset of hardening throughout the whole epidermis of the albino locusts (*C*, Fig. 2), just as they do in non-melanized areas of the normal strain, and it may be suggested that failure to form melanin, whether in the pale areas of the cuticle of normal nymphs or in the whole cuticle of albinos, may be due to the withholding by the epidermis of the necessary chromogen.

These observations were made during an investigation into the cuticle of the desert locust carried out at the University of Manchester and supported by the Anti-Locust Research Centre. A full report is being prepared.

Action of Diaphanol on Arthropod Cuticles

DIAPHANOL (a 50 per cent solution of glacial acetic acid saturated with chlorine dioxide) has been much used since its recommendation by Schulze[1] as a reagent for softening and bleaching arthropod cuticles. Its precise action, however, seems never to have been critically studied.

Chromatographic examination of cuticles of the adult cockroach *Periplaneta americana* after treatment with diaphanol reveals that after only a comparatively short time of 24 hr. the aromatic amino-acids have been destroyed. Prolonged treatment results in complete removal of all ninhydrin-positive material. Cuticles, after treatment with diaphanol, were hydrolysed with 6 *N* hydrochloric acid for 20–24 hr. and the hydrolysate evaporated to dryness, the residue being taken up in 10 per cent *iso*-propyl alcohol. Two-dimensional chromatograms were developed using butanol/acetic acid/water and aqueous phenol as solvents, the amino-acids being detected by spraying with a solution of ninhydrin in butanol. After treatment for 24 hr. with diaphanol both *ortho*- and *para*-tyrosines were absent, and proline also had been partially eliminated. After treatment for 6 weeks, only very minute quantities of ninhydrin-positive material could be detected after hydrolysis, and the spots on the chromatogram corresponded with glycine and aspartic acid. After treatment for 8 weeks no ninhydrin-positive material remained.

In tests carried out on the effects of diaphanol on individual amino-acids, it was found that after 18 hr. phenylalanine had been partially broken down, some alanine being present in the solution. After 3 days, all ninhydrin-positive material had been removed from the solution. When a mixture of tryptophan, *ortho*-tyrosine, *para*-tyrosine, proline, threonine, methionine, valine and glycine was placed in diaphanol the aromatic acids had disappeared after 18 hr. and proline was reduced in amount. All the acids had been destroyed after 5 weeks. As aromatic substances are responsible for tanning in many arthropod cuticles[2] the changes caused by diaphanol treatment are readily explained by its action on aromatic nuclei and individual amino-acids.

Diaphanol is stated to be a useful reagent for softening and bleaching chitinous materials but "has the disadvantage that it often spoils histological detail"[3]. This is not surprising in view of its action on amino-acids in general.

These observations were made while studying amino-acid metabolism in the cockroach *Periplaneta americana*.

Surviving Rat Skin Grafts in Mice

UNTIL recently, orthotopic transplantation of heterologous normal tissue could not be achieved in mammals. In 1956 it was demonstrated independently by Nowell *et al.*[1], Ford *et al.*[2] and Vos *et al.*[3] that a persistent proliferation of rat hæmatopoietic cells occurs in mice which survive a lethal total body dose of X-rays as the result of the administration of rat bone-marrow. More than one year after the transplantation in some of these mice all the erythrocytes and granulocytes were found to be of rat origin[4].

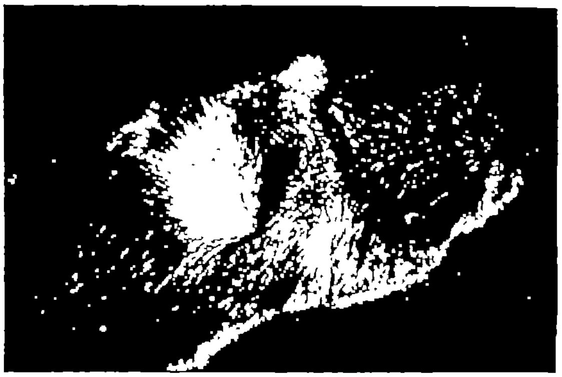

Fig. 1. Functional rat skin grafts in a mouse, 28 days after transplantation, 151 days after irradiation. This mouse died during anaesthesia

It seemed of interest to investigate whether these radiation-chimæras would accept skin grafts of the bone-marrow donor species. In the case of homologous bone-marrow transplantation in irradiated mice, successful grafting of the skin of the bone-marrow donor strain has been reported by Trentin[5]. The use of heterologous bone-marrow transplants permits a regular evaluation of the functional state of the marrow graft by identification of the erythrocytes and granulocytes[6]. Unfortunately the relatively high mortality which occurs in mice treated with rat bone-marrow limits the number of available animals.

In the present experiments irradiated *CBA* and F_1 (*CBA* ♂ × *C57 Bl* ♀) mice were protected with bone-marrow from an inbred rat strain (Wistar Albino Glaxo). The X-ray dose varied between 675 and 800 r. In 35 of the surviving mice small pieces of rat skin have been grafted at 24–151 days following the irradiation (Table 1). The method of free skin grafting[7] was used. In preliminary experiments, rat skin transplants into non-irradiated mice (37 cases) were found to slough within 12 days after the grafting.

At present, rat skin of a completely normal aspect is growing in 10 mice (Fig. 1). These grafts are between 52 and 108 days old. All the erythrocytes and granulocytes of the recipients are of rat origin. In nine cases the rat skin grafts are deteriorating. These hosts have a mixed population of rat and mouse erythrocytes and granulocytes. Sloughing of the rat skin grafts has been observed in three cases. In these mice no rat cells were found in the peripheral blood.

Table 1. SURVIVAL OF RAT SKIN GRAFTS IN LETHALLY IRRADIATED MICE TREATED WITH RAT BONE-MARROW

	No. of mice	Nature of erythrocytes and granulocytes
Dead between 14 and 63 days after transplantation	18*	—
Takes, showing normal rat skin	10	rat
Takes, in some stage of deterioration	9	mixed
Sloughed	3	mouse

* Eleven mice died 14 and 28 days after transplantation (30–59 days after irradiation) One mouse died 28 days after transplantation and 151 days after irradiation. One mouse died 63 days after transplantation and 88 days after irradiation.

Homologous (*C57 B1*) skin was grafted simultaneously with rat skin in 19 of the mice protected with rat bone-marrow and used in this study. In four of these cases the rat skin graft has taken excellently, while the homologous skin sloughed between 10 and 30 days after the transplantation. This may have been due to a production of antibodies, either by the foreign bone-marrow or by the host. The observation that irradiated mice which have been protected by F_1 marrow accept skin grafts of the other parent strain[8] points to the latter possibility.

Of the rat skin grafted radiation-chimæras 13 have died between 14 and 63 days after the transplantation. In all cases except one the skin graft appeared healthy at the time of death. In the older grafts a regrowth of hair had occurred.

Amino-Acid Composition of Adult and Fœtal Myoglobin of the Cow

In recent years some investigators have searched for a fœtal type of myoglobin[1–4]. The results obtained by Jonxis and Wadman[2] and Rossi-Fanelli and co-workers[3] suggest that some differences exist between the myoglobins of the adult and fœtal cow, particularly as regards resistance against alkali, solubility and ultra-violet spectral absorption. By using paper electrophoretic techniques, Singer *et al.*[4] showed the probable existence of a fœtal type of this muscle pigment in human beings. However, a sharp characterization of these fœtal proteins has not yet been accomplished. In this communication we report some experiments concerning the paper electrophoretic behaviour and the amino-acid composition of the adult and fœtal myoglobin of the cow.

For the preparation of the myoglobins the technique described by Boardman and Adair[5] was used with some modifications. Fœtuses five to six months old of cows of Friesian origin were used. After saturation of the water extract of the muscle with carbon monoxide, solid ammonium sulphate was added until 65 per cent saturation was reached (*p*H between 6 and 7). The precipitated proteins were removed by filtration. Next the concentration of ammonium sulphate in the filtrate was raised to 100 per cent saturation. The precipitate was dissolved in a small volume of distilled water and dialysed against a large volume of a 75 per cent saturated solution of ammonium sulphate. The concentration of the ammonium sulphate was gradually increased to 85 per cent saturation. The purity of the myoglobin remaining in solution was estimated by measuring the spectral absorption between 500 and 600 mμ after reduction with sodium dithionite and saturation with carbon monoxide (maximal adsorption[6] of carboxy myoglobin at 540 mμ). As shown in Fig. 1 a maximum of 576–578 mμ was reached after 85 per cent saturation. The myoglobin was again precipitated by raising the concentration of ammonium sulphate to 100 per cent saturation. The precipitate was dissolved in a small volume of distilled water and dialysed, first against water for 48 hr. and next against a 0·025 *M* citrate buffer solution *p*H 6·0 (sodium ion concentration, 0·075). An aliquot of this solution was subjected to chromatography on a column 10 cm. × 1·5 cm. of 'Amberlite *IRC 50*' (*XE 64*) using a 0·05 *M* citrate buffer solution *p*H 6·0 (sodium ion concentration, 0·15). The chromatographic result is roughly similar to that obtained by the English investigators for beef myoglobin[5]. The main component, which shows a maximum at exactly 578 mμ (Fig. 1), was used for the paper electrophoretic studies and the analysis of the amino-acid composition. No distinct differences were found between the extracts of muscles of adult and fœtal cows during the preparation of the pure myoglobin solutions.

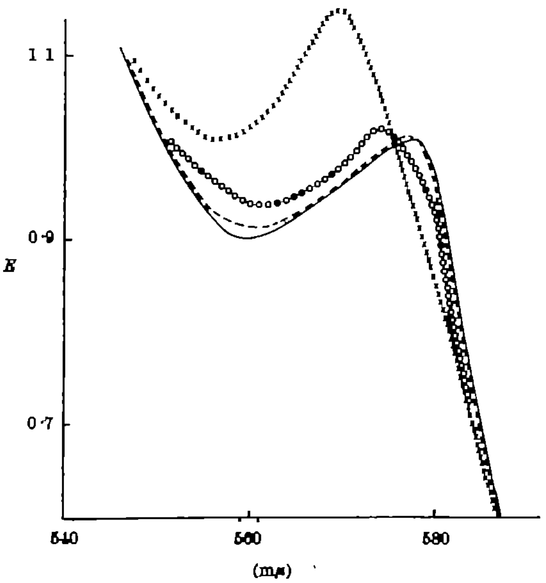

Fig. 1. Spectrophotometric curves of different myoglobin preparations: xxxx, after 70 per cent saturation; oooo, after 80 per cent saturation; ----, after 85 per cent saturation; ——, chromatography

The two myoglobin preparations were first studied by paper electrophoresis using a 0·06 *M* veronal buffer, *p*H 8·6. As shown in Fig. 2, the patterns of myoglobin *A* and *F* are similar. Similarly, with a 0·1 *M* phosphate buffer solution, *p*H 6·5, no differences were found. The spectral photometric curves of the two myoglobins in the ultra-violet light did not show appreciable differences in the position of the absorption maxima. The slight flexion in the curve of the fœtal myoglobin, as described by Rossi Fanelli *et al.*[3], could not be confirmed at 290 mμ.

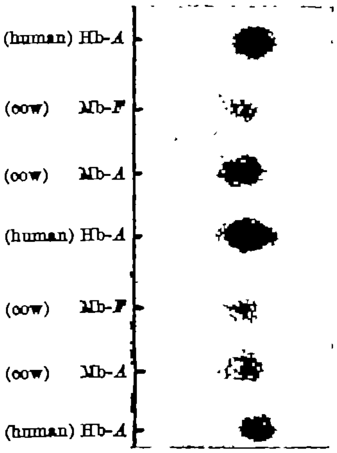

Fig. 2. The paper electrophoretic pattern of the myoglobins of the adult and fœtal cow

The amino-acid composition of the two proteins was estimated by the column chromatographic method of Stein and Moore[7], using 'Amberlite *IR* 120' (*XE* 69). The myoglobins were hydrolysed by refluxing about 50 mgm. of the protein with 200 ml. of 6 *N* hydrochloric acid. The results of the analyses of the amino-acid composition of the 48-hr. hydrolysates of the proteins are given in Table 1. They are also compared with those obtained for the hæmoglobins of the adult and fœtal cow. The amino-acid composition of the adult and fœtal cow hæmoglobin will be discussed elsewhere in detail. All analyses were carried out in triplicate. From Table 1 it is clear that no significant differences are present between the amino-acid compositions of the two myoglobin preparations. The amino-acid composition of the fœtal hæmoglobin, on the contrary, differs in the amounts of serine, alanine, *iso*leucine, histidine and lysine. From our results, however, it is impossible to decide definitely on the existence of a fœtal type of myoglobin in the cow. Such a component may exist, but if it does the chemical composition of this protein must be closely similar to that of the adult myoglobin.

We are much indebted to Drs. Moore and Stein for permission to study their new method of amino-acid analyses before publication, and to Prof. J. H. P. Jonxis for his advice and encouragement during this investigation. This work was supported by a grant from the Dutch Organization of Pure Research (Z.W.O.).

Table 1. AMINO-ACID COMPOSITION OF THE 48-HR. HYDROLYSATES OF THE MYOGLOBINS AND THE HÆMOGLOBINS OF THE ADULT AND FŒTAL COW

(Values are given in gm./100 gm. protein and are the mean of three analyses of different preparations)

Amino-acid	Myoglobin *A*	Myoglobin *F*	Hæmoglobin *A*	Hæmoglobin *F*
Aspartic acid	10·0	10 0	11·9	11 5
Threonine	3·3	3·2	4·8	4 3

Myoglobins from Sheep Homozygous for Different Hæmoglobin Types

IN recent years, the presence of different abnormal hæmoglobins not only in human beings but also in some species of animals has been described. It is still a question whether this genetically controlled deviation is limited to the synthesis of hæmoglobin or whether other abnormal proteins (for example, the related myoglobin) are synthesized at the same time. Singer *et al.*[1] studied this problem in patients with sickle cell anæmia; they used spectroscopic and electrophoretic methods, but failed to demonstrate the presence of an abnormal type of this muscle protein.

Since many kinds of animals are known to possess different types of hæmoglobin, the possibility exists of investigating the myoglobin of animals which are homozygous for one of the different hæmoglobins. Recently, we described[2] some characteristic properties of two different hæmoglobins of the sheep (hæmoglobin I and II). These two proteins differ in electrophoretic and chromatographic behaviour, in solubility, resistance to alkali and amino-acid composition. In this communication we present the results of an investigation concerning possible differences between the myoglobins obtained from sheep which were homozygous for one of these two different hæmoglobin types. Characterization of the two proteins was attempted by electrophoretic and spectroscopic techniques and by the analyses of the amino-acid compositions.

The muscle proteins were prepared as described for cow myoglobin[3]. It was found that during isolation and purification the behaviour of sheep myoglobin was identical with that of cow myoglobin. The paper electrophoretic experiments were carried out with a 0·06-*M* barbital buffer solution, *p*H 8·6, using Whatman 3 *MM* paper. As shown in Fig. 1,

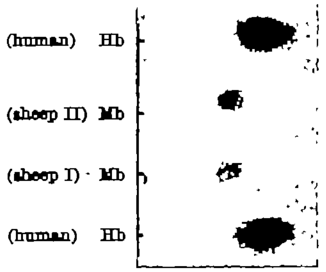

Fig 1. Paper electrophoretic pattern of the two sheep myoglobins

Table 1. AMINO-ACID COMPOSITION OF THE MYOGLOBINS AND HÆMOGLOBINS OF SHEEP HOMOZYGOUS FOR ONE OF THE TWO HÆMOGLOBINS. (Values are given in gm./100 gm. protein)

Amino-acid	Myo-globin-I	Myo-globin-II	Hæmo-globin-I	Hæmo-globin-II
Aspartic acid	9·2	9·6	13·5	12·5
Threonine	3·2	2·9	4·45	5·1
Serine	2·9	3·15	4·15	4·85
Glutamic acid	13·35	13·8	7·4	8·1
Proline	1·9	1·7	3·35	3·5
Glycine	5·7	5·4	5·1	3·95
Alanine	8·2	8·0	9·95	8·6
Valine	6·1	6·1	10·85	11·15
Methionine	2·8	2·95	1·8	
*iso*Leucine	4·65	4·7	0	0
Leucine	13·7	14·15	16·1	16·1
Tyrosine	2·25	2·6	2·6	3·05
Phenylalanine	7·9	8·3	7·05	7·6
Histidine	9·4	9·2	8·15	8·2
Lysine	15·5	15·25	8·7	8·5
Arginine	2·0	2·05	4·05	4·2
Total	108·75	109·85	107·2	105·6

no difference could be detected. Also the ultra-violet spectral absorption curves of the two proteins were completely similar. Amino-acid analyses of the 48-hr. hydrolysates of the two myoglobins were carried out, using the column chromatographic method of Stein and Moore[4] with the cation exchanger 'Amberlite *IR* 120' (*XE* 69). The results of duplicate experiments are given in Table 1; they are compared with the values described for the two hæmoglobins of the sheep. From these results it will be clear that in this respect also there are no significant differences between the two myoglobin preparations. The amino-acid analyses of the two hæmoglobins, on the contrary, showed the existence of small but distinct differences in the amounts of aspartic acid, glycine, alanine, glutamic acid, threonine and serine.

Summarizing, it may be concluded that our investigations fail to reveal any difference in the spectroscopic and electrophoretic behaviour and in the amino-acid composition of the myoglobins of sheep with different types of hæmoglobins. Our results do not support the hypothesis that the genetically controlled abnormality of producing more than one type of hæmoglobin in one species of animal is not limited to this protein particularly.

This investigation was supported by a grant from the Dutch Organization for Pure Research (Z.W.O.).

Abnormal Hæmoglobins in Monkeys

WE wish to report the finding of abnormal hæmoglobins in two species of monkeys. The monkeys had been shot in the Uganda Protectorate as part of another investigation and their blood has been subject to paper strip electrophoresis. At first lysed whole blood was used, but later larger specimens were collected and hæmoglobin solutions prepared. Hæmoglobins which behaved on electrophoresis like human *AA* hæmoglobin solutions were taken as the normal reference point.

Table 1

Species	No.	Electrophoresis at pH 8·6
Cercopithecus ascanius	37	all normal
Cercopithecus aethiops	3	all normal
Cercopithecus neglectus	6	all normal
Cercopithecus mitis	6	5 normal and 1 abnormal
Cercocebus albigena	16	all abnormal
Colobus badius	2	both normal
Colobus abyssinicus	3	all normal

Table 1 shows the numbers of monkeys of each species examined and the findings on electrophoresis at pH 8·6.

Cercopithecus mitis. Five specimens moved normally. One specimen had a fast-moving component which did not separate from the normal hæmoglobin present but formed a streak ahead of it. The leading edge of the hæmoglobin lay ahead of a known example of human hæmoglobin *J*[1]. At pH 6·5 the abnormal hæmoglobin moved slowly but not backwards and the same patterns were preserved after freezing at − 20° C. This fast component therefore behaves on electrophoresis in the same way as human hæmoglobin *I*[2], and the hæmoglobin composition of this monkey resembles *AI*. The fast component of this mixture differs from the hæmoglobin *I* described by Rucknagel *et al.*[3] in constituting a larger proportion of the total.

Cercocebus albigena. At pH 8·6 all the hæmoglobin specimens from this species moved as a single band

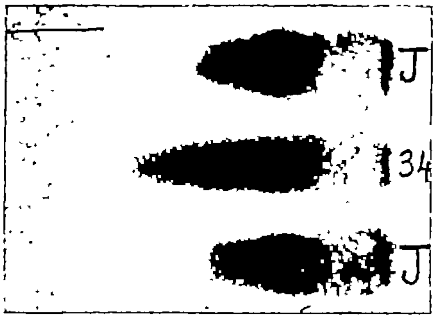

Fig. 1. Electrophoretic patterns of hæmoglobin from *Cercopithecus mitis* with the fast-moving component (34) compared with hæmoglobin *J* at pH 8·6

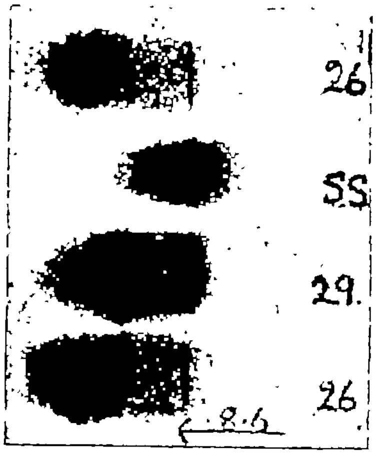

Fig. 2. Electrophoretic patterns of hæmoglobin from *Cercocebus albigena* (29) running behind a normal *Cercopithecus ascanius* (26) and ahead of a hæmoglobin from human sickle cell anæmia (*SS*) at pH 8·6

Table 2

Species	No.	Results
Cercocebus albigena	7	trace of A.R.H. in all
Cercopithecus ascanius	9	trace of A.R.H. in 7
Colobus badius	1	trace of A.R.H. present
Colobus abyssinicus	2	trace of A.R.H. in both

slower than normal hæmoglobin but faster than human hæmoglobins *S* or *D*. The bands lay slightly nearer the normal or *A* position than the *S* position. This position corresponds to hæmoglobin *GG* in humans[3]. At *p*H 6·5 no difference could be observed between these and normal hæmoglobin.

At the suggestion of Dr. H. Lehmann some of the specimens were examined for alkali-resistant hæmoglobin (A.R.H.) by Singer's method. The results are shown in Table 2.

The traces of alkali-resistant hæmoglobin present were less than 4·0 per cent and too small to determine accurately. The slow movement of the hæmoglobins from the species of *C. albigena* is not, therefore, explicable on the grounds of small amounts of alkali-resistant hæmoglobin. The ages of the monkeys were not accurately known but none was an infant and some were old adults, so that by analogy with humans in whom alkali-resistant fœtal hæmoglobin has largely disappeared by the age of three months its presence would not be expected in these monkeys.

The presence of two components in the hæmoglobin of one specimen of *Cercopithecus mitis* indicates a heterozygous condition, and thus the presence of more than one allele affecting hæmoglobin in the population. The presence of a slow hæmoglobin, moving as a single band in all specimens of *Cercocebus albigena*, indicates either fixation in the population of a different allele from that controlling hæmoglobin *A*, or the fixation of a modifying allele or alleles at other loci.

Both these findings suggest the value of further hæmoglobin studies in populations of non-human primates. Further studies are required to find out if the abnormal hæmoglobins reported here are identical with those human hæmoglobins with similar electrophoretic properties. If this should be proved, then non-human primates may become valuable for research in human genetics.

Occurrence of a Cardio-active Principle in Spleen

The work of Rein[1] and Pinotti[2] showed that the liver can release a substance into the circulation which is capable of improving the efficiency of the heart in a manner which could not be explained solely on hæmodynamic grounds. These two authors believed that the liver material acted by improving the energy metabolism of the heart, leading to greater economy of cardiac work. Later work reported by Rein[3,4] indicated that the stimulus for the release of the active liver principle was cardiac hypoxia, which caused release of a material from the spleen into the blood stream. This material was transported to the liver, where it served as stimulus for the release of the active liver principle. Rein's work has shown that the materials involved in the reaction must be of a hormonal nature. In 1952, Green[5] described an extract from the non-saponifiable components of ox liver which exerted a positive inotropic action on the isolated papillary muscle of the cat. This work has been confirmed here, and an examination has been made of extracts of spleen to determine whether any cardioactive material is present in this organ.

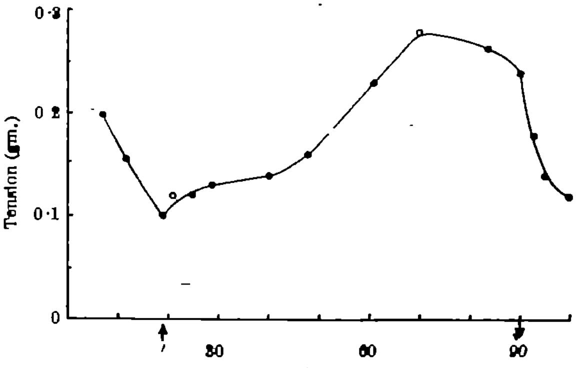

Fig. 1

Freshly removed ox spleen was minced and freeze-dried. Serial extractions of the freeze-dried material were performed in a Soxhlet apparatus using petroleum ether (40°–80° C. fraction), di-ethyl ether, acetone and methanol, all solvents being purified and re-distilled before use. The various fractions were evaporated to dryness over a water-bath and were stored in stoppered vessels at 4° C. For each experiment a weighed quantity of extract was dissolved or suspended in a quantity of physiological medium of identical composition, *p*H and temperature to that bathing the preparation.

Using the isolated papillary muscle of the cat, we were able to demonstrate the absence of positive inotropic activity in the petroleum ether and di-ethyl ether fractions, but the acetone fraction contained a cardio-active material which gave a positive inotropic effect. A typical record for this extract is shown in the graph of Fig. 1. A similar positive inotropic effect was observed on the isolated Langendorff heart of the guinea pig, which showed an increased amplitude of beat, together with a slight increase in rate and coronary flow.

The method of extraction precludes this effect being due to ionic changes since no inorganic salts could appear in this extract. The extract was also free of substances such as histamine and acetyl choline, for when tested on isolated guinea pig ileum no contraction resulted with quantities greater than those required to produce a positive inotropic effect on the heart. Work is at present in hand to produce a purer preparation.

We wish to acknowledge grants in aid of this investigation from the National Health and Medical Research Council, and the Kahn Fund for Medical Research, and to extend our thanks to Mr. J. D.

Mellor, of the Commonwealth Scientific and Industrial Research Organization, for provision of freeze-drying facilities.

Hydroxyproline and Thermal Stability of Collagen

Gustavson[1] has recently directed attention to the importance of hydroxyproline residues in determining the hydrothermal stability of a collagen. He examined collagen samples from two broad sources, namely, mammalian and teleost connective tissue, and his findings demonstrated a direct relationship between the hydroxyproline content of a collagen and its shrinkage temperature. He considers that hydroxyproline will form interchain hydrogen bonds between its hydroxyl group and the carbonyl oxygen of an adjacent peptide grouping and may also be involved in the formation of ester links between polypeptide chains, thus playing a very important part in determining the stability and general reactivity of a collagen fibre. The evidence for assigning such a function to the hydroxyproline residue has, however, been derived from a study of many animal species. Furthermore, there is a growing body of evidence[2–4] which indicates that the reactivity of a collagen fibre depends on age and it still remains to be established whether variations in the hydroxyproline content can account for the differing degrees of reactivity with age, shown by collagen obtained from a single animal species.

We now wish to report some findings which bear on this question. In a study of the action of collagenase on samples of dermal collagen from sixty individuals, Keech[3] found that fifty of these responded normally to the enzyme, the response being a function of age. Eight samples, however, failed to show any digestion as assessed by the electron microscope, that is, were collagenase-resistant, while two other samples, taking into account their age, reacted excessively. As part of a more detailed investigation into those collagen preparations which show an abnormal response towards collagenase, hydroxyproline content and shrinkage temperature were determined. In all, fourteen samples of the same preparations used in previous work were examined, namely, human abdominal skin from persons of different age, purified by the method of Neuman[5] as shortened by Keech[3]. These collagen samples were classified into groups: group 1, ten showing normal response towards collagenase; group 2, two which were collagenase-resistant; and group 3, two which were hypersensitive towards collagenase.

Hydroxyproline content was determined using the method of Martin and Axelrod[6], to an accuracy of ± 5 per cent. The range of temperature over which the samples shrunk was determined by the microscopic method of Borasky and Nutting[7]. Small fibres were teased from the samples and rehydrated in distilled water for one hour, before mounting in the heating chamber. Heat was applied at a constant rate (2 deg. C./min.) and, so far as possible, fibres of similar size were used. Following Borasky and Nutting, the range of shrinkage was determined by recording both temperatures at which the fibres started to shrink and also the final one at which no further change in dimensions occurred.

Table 1

	No.	Age (years)	Hydroxyproline (gm./100 gm. dry collagen)	Range of shrinkage (° C.)
Group 1 (control)	1	7	14·3	65–69
	2	9	13·6	64·5–68·5
	3	19	13·7	65–66
	4	23	13·6	65·5–69
	5	27	14·2	64–67·5
	6	36	13·6	62–69
	7	42	13·1	65·5–69·5
	8	48	12·5	63–68
	9	57	13·1	70·5–74
	10	89	12·8	62–68
Group 2 (collagenase resistant)	11	18	14·0	72–77
	12	61	12·3	72–79·5
Group 3 (collagenase hypersensitive)	13	20	14·0	60–67
	14	52	12·5	60·5–65

The results are shown in Table 1. The hydroxyproline levels all lie within the range 12·3–14·3 per cent and within the accuracy of the determination these are reasonably constant, though there is a tendency in all three groups for the values to decrease with age. Until more accurate methods of determination become available, all that can be said, therefore, is that the hydroxyproline content of collagen preparations from one animal species does not vary much with age. On the other hand, the temperature-ranges of shrinkage shown by the three groups are quite distinct. With the exception of sample 9, the collagens in the control group (group 1) shrank over the range 62–69·5° C., the collagenase-resistant samples in group 2 over 72–79·5° C., while those in group 3, which are hypersensitive towards collagenase, shrank over a lower temperature-range, namely, 60–67° C. Furthermore, even with samples of similar age, although the hydroxyproline levels lie fairly close together, the temperature-ranges of shrinkage are again quite distinct. It seems probable, therefore, that the views of Gustavson may require amending since the thermal shrinkage of collagens from one animal species may be independent of the hydroxyproline content and that other factors, which depend on age, may be more important in determining the stability and general reactivity of such protein systems.

We wish to thank Dr. M. K. Keech of the Department of Medicine for supplying the samples of human dermal collagen, Mr. J. W. Czerkawski of the Nuffield Gerontological Unit for assistance in the hydroxyproline determinations, and Mr. A. Gill of the Department of Leather Industries for the shrinkage-temperature determinations.

Catechol Compounds in Rat Tissues and in Brains of Different Animals

ESTIMATES, made by the ethylenediamine method, of adrenaline and noradrenaline concentrations in rat tissues have already been reported[1]; they varied seasonally[2]. Experiments have now been carried out to investigate the occurrence of other catechol compounds. Some material, probably hydroxytyramine, has consistently been found in rat liver and spleen, and particularly in brain; other brains have been analysed.

Tissues were extracted with acid methanol as before[1]; after treatment with alumina they were passed, at pH 6·5, over columns of 'Amberlite *IRC*-50' cation exchange resin, to separate acidic and neutral material, if present, from basic compounds; the latter are retained by the resin and eluted. Noradrenaline (N) and adrenaline (A) were estimated in the eluate as fluorescent trihydroxyindole derivatives[3]: the eluates were also condensed with ethylenediamine dihydrochloride (ED) and readings taken with a yellow filter[4]; when part of this ethylenediamine dihydrochloride-fluorescence was not accounted for by noradrenaline and adrenaline it was designated *X*; concentrations of *X* have been calculated in terms of hydroxytyramine (H) with which it may be identical. The condensation product of hydroxytyramine with ethylenediamine dihydrochloride has about one-third of the fluorescence intensity of that of adrenaline.

If present, 3 : 4-dihydroxyphenylalanine (dopa) and 3 : 4-dihydroxyphenylacetic acid (dopac) would appear in the resin filtrate; 3:4-dihydroxyphenylalanine forms a fluorescent indole derivative; both form fluorescent compounds with ethylenediamine dihydrochloride; these, unlike those formed by noradrenaline, adrenaline and hydroxytyramine, are more soluble in saturated aqueous solutions of sodium chloride than in *iso*butanol; the aqueous solutions were extracted with *iso*butanol as usual, but both phases were read fluorimetrically. 3 : 4-Dihydroxyphenylalanine and basic compounds can be separated from acidic catechol compounds by using 'Zeokarb 225' resin.

X was present in varying concentration in extracts of whole brains from rats analysed at different times of the year; it had the R_F value of hydroxytyramine[5]; it was present also in whole brains from guinea pigs, rabbits and chicks. Neutral and acid catechol compounds, if present, were in amounts too small to be identified. By contrast, preliminary analysis of a normal human brain extracted in 0·05 *N* hydrochloric acid 30 hr. after death showed that noradrenaline, adrenaline and *X* were responsible for only 40 per cent of the ethylenediamine dihydrochloride-fluorescence, and that 3 : 4-dihydroxyphenylalanine was probably present. The presence of the latter was confirmed by paper electrophoresis[6] of an eluate from 'Zeokarb 225' resin, and by paper chromatography[5] of a filtrate from *IRC*-50 resin. The chromatogram also showed a spot, less intense than that due to 3 : 4-dihydroxyphenylalanine, with an R_F value slightly higher than 3 : 4-dihydroxyphenylacetic acid, and probably due to some other catechol acid; its concentration has been calculated in terms of 3 : 4-dihydroxyphenylacetic acid. Paper chromatograms[5] of the eluate from *IRC*-50 resin gave quantitative recoveries (92–98 per cent) of noradrenaline, adrenaline and *X*; *X* had the R_F value of hydroxytyramine.

Table 1. CONCENTRATIONS OF CATECHOL COMPOUNDS IN WHOLE BRAINS OF DIFFERENT ANIMALS

Animal	Total ED-fluorescence in terms of A (mμgm. A/gm. brain)	N	A	X	Dopa	Dopac
		(mμgm./gm. brain)				
Man	110	21·2	4·38	94·2	200	90
Rabbit	229 183	126 110	20·2 22·1	288 176	— —	— —
Guinea pig	173 299	106 110	37·6 43·3	177 410	— —	— —
Rat (mean ± standard error)*	447 ± 65·1	219 ± 15·2	69·3 ± 6·95	642 ± 119	—	—
Chick	151 142	66·8 50·8	36·8 30·2	130 185	— —	— —
Frog	1,175 1,140	— —	— —	— —	— —	— —

* 5 estimations.

Concentrations of catechol compounds found in brains of different animals analysed at the same times showed considerable differences and are shown in Table 1: the estimates have not been corrected for oxidation of noradrenaline at pH 3·5 (trihydroxyindole method)[3]. *X*, from its higher concentration in rat and rabbit compared with human brain, does not appear to be identical with encephalin[7], especially since it is stated that extraction of encephalin is slight in alcoholic compared with aqueous solution[8]; in the present experiments alcoholic solution was used for all except human brain. However, the estimates of fluorescence in eluates and filtrates of the human brain treated with *IRC*-50 resin showed that losses had occurred, perhaps in the filtrates but more probably through retention of some substance by the resin. Frog brains are included in Table 1; extracts were treated with alumina only and the ethylenediamine dihydrochloride-fluorescence (yellow filter) calculated in terms of adrenaline.

Other rat tissues, heart, kidneys, liver, spleen and diaphragm, have also been analysed; as in brain, most or all of the ethylenediamine dihydrochloride fluorescence has been due to noradrenaline, adrenaline and *X*. *X* has been present in varying concentrations in liver and spleen, always forming a smaller proportion of the catecholamines than in brain; it has not always been found in heart, kidneys and diaphragm. Its concentration, as well as those of noradrenaline and adrenaline, appears to vary seasonally; the course of these variations is still being investigated. There is evidence that they depend on the adrenal cortex: the ethylenediamine dihydrochloride-fluorescence in hearts of rats bilaterally adrenalectomized 6–10 weeks previously was less than, or greater than, that in hearts of control rats analysed simultaneously, according as the level in normal rats had increased or decreased since the time of operation. The medulla does not seem to be responsible: adrenal demedullation produced a slight increase of the ethylenediamine dihydrochloride-fluorescence in hearts, and a considerable decrease in kidneys, as judged by simultaneous analysis, in November, of intact and demedullated rats; comparison of the latter with intact rats analysed at the time of operation (September) showed large increases of catechol compounds in both tissues since operation.

I am grateful to Dr. H. Weil-Malherbe for advice, to Dr. D. C. Caldwell for supplying the human brain, and to Messrs. Poultry Packers (Essex), Ltd., for fresh chicks' heads. The work was supported by a grant from the Medical Research Council.

Conversion of Pyruvic Acid to Alanine in the Silkworm Larva

As reported earlier[1], we tried to isolate keto acids of importance physiologically in the body fluid and the silk-glands of the silkworm larvæ and found that there were present glyoxylic, α-keto-glutaric, oxalacetic and acetoacetic acids. Pyruvic acid, which is found usually in mammals, was not recognized in the silkworms. The present work was carried out to determine whether, although pyruvic acid is not found in the body fluid and the silk-glands, metabolism involving pyruvic acid takes place in the silkworm.

The silk-glands, the alimentary canals, also the muscle and the fat tissues obtained from five larvæ (Si 110 × Nichi 122) on the sixth day of the fifth instar were washed with cold water and suspended in $M/15$ phosphate buffer, pH 7·4, and homogenized in homogenizer and made up to 5 ml. Each sample was placed for 5 hr. at 0° and then kept at − 18° overnight. The insoluble proteins obtained by thawing the ice at room temperature were discarded, and the supernatant solution was used as the enzyme solution. To 1 ml. portions of each enzyme solution were added 0·5 ml. of 0·1 M L-glutamic acid, 0·5 ml. of 0·1 M sodium pyruvate and 0·1 ml. of $M/15$ phosphate buffer, pH 7·4, containing 0·1 μc. of sodium pyruvate-2-^{14}C, and this mixture was incubated for 60 min. at 38°. The solutions of L-glutamic acid and sodium pyruvate were made in $M/15$ phosphate buffer, pH 7·4, immediately prior to use. The reaction was stopped by adding 200 mgm. of trichloroacetic acid. This filtrate was analysed by means of paper chromatography, using n-butanol/acetic acid saturated with water (n-butanol, 95/acetic acid, 5) as a solvent. Two spots were revealed on a strip which was sprayed with ninhydrin in the usual way: one of them (R_F 0·42) was alanine and the other (R_F 0·16) was glutamic acid remaining in the reaction mixture. The strip was scanned for radioactivity by an SC-16 windowless gas-flow counter. As shown in Fig. 1, higher radioactivity was recognized at the position of the alanine. A lower radioactivity was also recognized at the position of R_F 0·14, at nearly the same position as glutamic acid, but this proved, by comparison with the behaviour of pure sodium pyruvate-2-^{14}C on a chromatogram, to be due to the appearance of isotopic sodium pyruvate remaining in the reaction mixture on the chromatogram. Radioactivities of the alanine spot on the chromatograms obtained from three tissues of the silkworm are presented in Table 1. The results seem to suggest that the synthesis of alanine from pyruvic acid with glutamic acid takes place in the silk-glands, the alimentary canal, and muscle and fat tissues. Recently the occurrence of the transamination reaction in the silkworm was also indicated by Bheemeswar *et al.*[2] and Koide *et al.*[3].

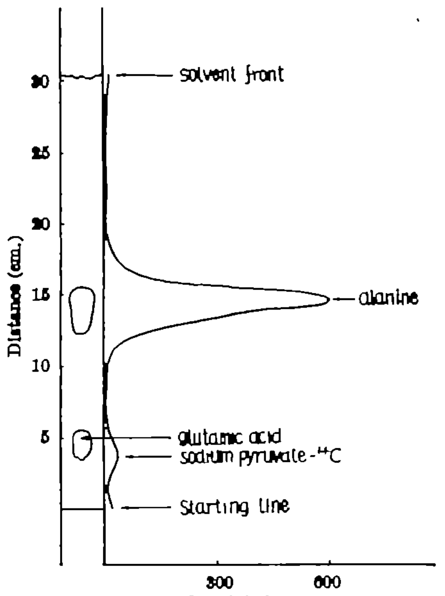

Fig. 1. Radioactivity of chromatogram of reaction mixture n-butanol/acetic acid saturated with water run from the starting line

Table 1. RADIOACTIVITIES OF THE ALANINE SPOT ON THE CHROMATOGRAMS

Tissues	Counts/min. of alanine spot formed
Posterior division of silk-gland	420
Alimentary canal	330
Muscles and fat tissues	273

As glutamic acid and aspartic acid are the main constituent amino-acids of the proteins of the mulberry leaves, this reaction, which produces alanine from pyruvic acid with glutamic acid, seems to be of special importance in the synthesis of the alanine (25 per cent) of the silk, as well as in the formation of alanine by β-decarboxylase[4] from aspartic acid in the silkworm. Florkin *et al.*[5] demonstrated, using radioactive phenylalanine-1-^{14}C, that the carboxyl carbon of phenylalanine was not utilized for the synthesis of alanine of the silk by the silkworm. Recently I ascertained that the carbon-14 of the sodium pyruvate-2-^{14}C given to silkworms appeared in the alanine isolated from the cocoon fibres produced by these silkworms, and glutamic acid and aspartic acid played the most important part at the synthesis of alanine from pyruvic acid with amino-acids[6].

Activation of Polynucleotide Phosphorylase by Salts

In the course of purification studies of polynucleotide phosphorylase (polyase) from *M. lysodeikticus* we have on several occasions noticed that, after dialysis against buffers at low ionic strength or distilled water, considerable loss of enzyme activity occurred. With the addition of a salt such as sodium acetate or potassium chloride the activity of the enzyme was restored. The activation by potassium chloride of the polymerization of adenylic acid from adenosine diphosphate, determined by rate of release of orthophosphate at *p*H 9·5, is shown in Fig. 1. The optimum salt concentration is 0·2 *M* potassium chloride. Higher concentrations of the salt become inhibitory. Parallel studies based on the determination of polymer concentrations yielded identical results[1]. The following salts activate in the order: $KCl > NaCl > Na_2SO_4 = HCOONa > CH_3COONa > LiCl$.

The degree of activation at any particular normality and the maximum extent of activation is dependent on both the cation and anion and the substrate concentration.

Table 1

Potassium chloride concentration	0·02 *M*	0·04 *M*	0·1 *M*	0·2 *M*	0·6 *M*
V_m^* (rel.)	1·55	1·39	1·46	1·38	1·86
$K_m^* \times 10^{-4}$	12·6 *M*	7·10 *M*	5·63 *M*	3·24 *M*	13·8 *M*

The effect of varying substrate concentrations on the rate of polymerization in the absence and in the presence of 0·2 *M* potassium chloride at *p*H 9·5 is illustrated in Fig. 2. The rate–substrate curve at low concentration of adenosine diphosphate is non-linear and has a slope greater than that of the control without potassium chloride. At high substrate concentrations the rate–substrate curve is linear, and has a slope equal to that of the control and independent of the concentration of potassium chloride. The non-linear portion of the curve fits the Michaelis–Menten equation. Table 1 lists the K_m^* and V_m^* values calculated at various concentrations of potassium chloride. With the exception of the experiment in 0·6 *M* potassium chloride, the maximum velocity, V_m^*, is unaffected by salt concentrations. However, the apparent Michaelis constant, K_m^*, changes with salt concentration. Indeed, the activation curve given in Fig. 1 parallels the change in $1/K_m^*$ with concentrations of potassium chloride. The values of K_m^* are strongly dependent upon the extent of removal of the salts in the enzyme preparation, particularly ammonium sulphate. The polymerization of other polymers (polycytidylic and polyuridylic acids) is also activated to a comparable degree, depending on the experimental conditions.

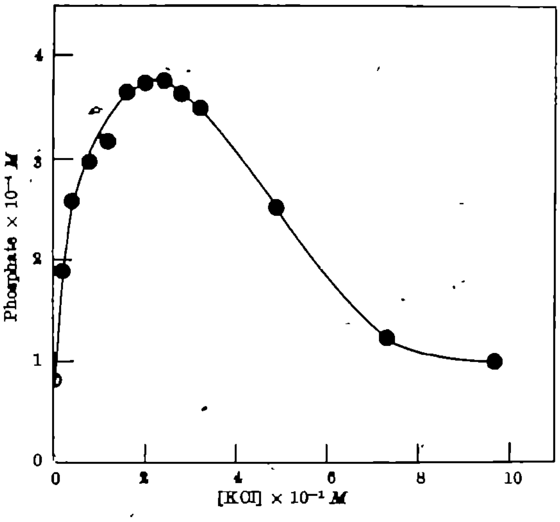

Fig. 1. Rate of orthophosphate liberation as a function of concentration of potassium chloride. Reaction mixture consisted of 0·5 ml. 0·2 per cent adenosine diphosphate, 0·5 ml. enzyme, 0·5 ml. 2 × 10⁻³ *M* magnesium chloride, 0·2 ml 0·5 *M* tris buffer, *p*H 9·5, and 0·8 ml. of potassium chloride solution. Temperature 37° C., incubation 20 min. Rate is recorded as increase in orthophosphate concentration

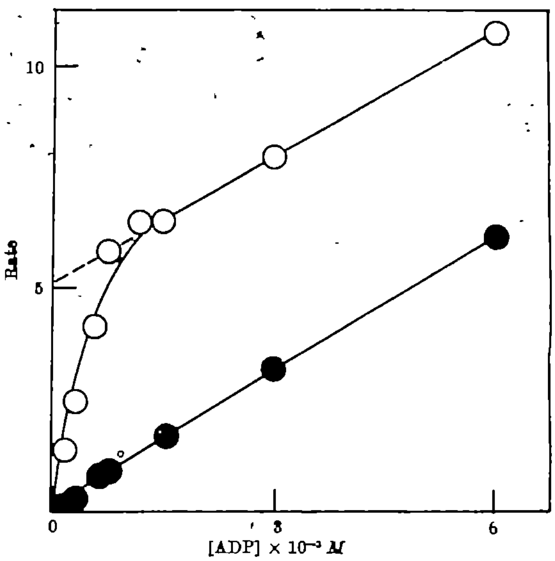

Fig. 2. Rate of orthophosphate liberation as a function of concentration of adenosine diphosphate with 0·2 *M* potassium chloride ○; and without addition of potassium chloride ●. Reaction mixture consisted of 0·5 ml. enzyme, 0·5 ml. 2 × 10⁻³ *M* magnesium chloride, 0·2 ml. 0·5 *M* tris buffer *p*H 9·5, 0·5 ml. water or 1·0 *N* potassium chloride and 0·8 ml. adenosine diphosphate solutions. Temperature 37° C., incubation 10 min. Rate is recorded in arbitrary units

The presence of high salt concentration alters the degree of activation by magnesium[2]. The value of V_m^* increases with concentration of magnesium but, depending on the concentration of magnesium, K_m^*/V_m^*, does not vary appreciably. The linear portions of the rate-substrate curves shown in Fig. 1 are affected equally by magnesium. The curvature of the non-linear portion is decreased.

From these preliminary studies, we conclude that ionic strength influences the binding of the substrate by the enzyme and probably by the enzyme–polymer complexes. The marked effect of magnesium on V_m^* and on the linear portion of the rate–substrate curve suggests that magnesium may play a part in the events following the binding of the substrate to the enzyme or to the enzyme–polymer complexes. However, it is also possible that magnesium itself becomes limiting with increasing salt and substrate concentrations.

The marked sensitivity of polyase to changes of salt concentration, particularly at low salt concentrations, must be taken into consideration in measurements of activities of the enzyme in various tissues and extracts, and in measurements of the relative activities of such preparations toward specific nucleoside 5′-diphosphates.

Anthocyanidins of *Lochnera rosea*

IN a survey of the anthocyanin flower pigments of plants growing in Trinidad[1], it was found that *Lochnera* (*Vinca*) *rosea* (Apocynaceae) contained an anthocyanin the aglycone of which was not identified. The fresh petals gave on chromatography a major glycosidic component of R_F 0·29 together with traces of two others R_F 0·23, 0·18 in the *n*-butanol/acetic acid/water (40 : 10 : 50) solvent used.

The pigments have now been further investigated. After acid hydrolysis a main pigment was found together with traces of two others. The two minor anthocyanidins were shown by chromatography to be petunidin and malvidin and to be derived from the two minor glycosidic components.

The major anthocyanidin was isolated as follows: fresh flowers (800 gm.) were extracted with 0·1 *N* hydrochloric acid (1·5 l.). The extract was made 2 *N* with hydrochloric acid and boiled for 15 min. After cooling the anthocyanidins were extracted with *n*-butanol (500 ml., then 250 ml.). The combined butanol extract was mixed with water (250 ml.) and light petroleum (2·5 l.) and the bottom layer added to a column of cellulose powder (40 × 3·7 cm.). The anthocyanidins were adsorbed on the top 5 cm. and were developed with *n*-butanol/2 *N* hydrochloric acid (top layer). The anthocyanidins and brown materials separated as discrete bands. This is a general and useful method of isolating anthocyanidins in quantity from crude extracts of flowers.

When the main anthocyanidin band had moved three-quarters of the way down, the column was sucked dry, extruded, and the band cut out. The pigment was extracted with methanol, the solution concentrated *in vacuo* to small volume and diluted with light petroleum. The precipitated pigment was dried *in vacuo*, dissolved in ethanol, and dry hydrochloric acid was passed in a 10 per cent concentration. On standing at 0° C. small regular cubic prisms (56 mgm.) of the main anthocyanidin separated. Found, after repeated recrystallization, C, 56·8; H, 4·7; OCH_3, 23·5: $C_{18}H_{17}O_7Cl$ requires C, 56·8; H, 4·5; OCH_3, 24·4 per cent.

From colour properties[2] the substance obviously belongs to the delphinidin series, and from analysis it is a trimethyl delphinidin. It could not be separated from added hirsutidin on paper chromatography in several solvents (R_F in the 'Forestal'[3] solvent 0·73–0·74). Bearing in mind the possibility of methylation in the 5 instead of the 7 position, as in hirsutidin, the anthocyanidin is provisionally identified as hirsutidin, known previously only in Primulaceae[4].

Three anthoxanthins also occur in the flowers: one has been identified certainly as kaempferol, and a second provisionally as quercetin; the third has not yet been identified. *Lochnera* thus joins the list of plants bearing unrelated anthocyanidins and flavonols in the flowers. Genetical investigations of flower colour are in progress.

We are indebted to Dr. E. C. Bate-Smith for supplying us with a sample of hirsutidin for comparison.

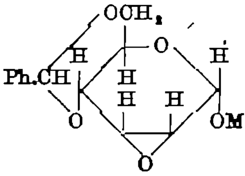
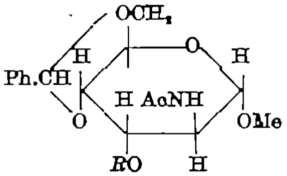
Characterization of 2-Amino-2-Deoxy-D-Altrose

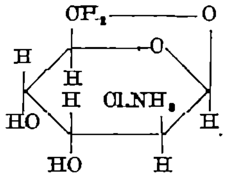
THE action of methanolic ammonia on methyl 2 : 3-anhydro 4 : 6-*O*-benzylidene-α-D-allopyranoside (I) followed by acetylation (pyridine – acetic anhydride) of the isolated amino-compounds yielded, as the major product (45·7 per cent), after recrystallization from aqueous-methanol, methyl 2-acetamido 4 : 6-*O*-benzylidene 2-deoxy-α-D-altropyranoside (II), melting point 188–189°, $[M]_D + 218°$ (acetone). (Found: C, 55·6, 55·8; H, 6·8, 6·7; N, 4·1. $C_{16}H_{21}O_6N.H_2O$ requires C, 56·3; H, 6·7; N, 4·1 per cent).



(I)



(II) $R = H$
(III) $R = CH_3.C_6H_4.SO_2$



(V)

The structure of (II) was indicated by the following observations.

(*a*) Elemental analysis.

(*b*) The infra-red absorption spectrum, in which the strong absorption at 1,725–1,749 cm.$^{-1}$, characteristic of the *O*-acetyl carbonyl group[1], was absent; but strong absorption at 1,651 cm.$^{-1}$ (N-acetyl carbonyl[1]) was present. Methyl 3-acetamido 2-*O*-acetyl 4 : 6-*O*-benzylidene 3-deoxy-α-D-glucopyranoside, the well-studied[2] minor product of the above reaction, showed strong absorption at 1,726 cm.$^{-1}$ and 1,634 cm.$^{-1}$.

(*c*) With excess toluene-*p*-sulphonyl chloride in pyridine, II gave a mono-*O*-toluene-*p*-sulphonate (III), melting point 174° (decomp.), $[M]_D + 296°$ (acetone). (Found: C, 58·0; H, 5·6; N, 3·0; S, 7·2. $C_{23}H_{27}O_8NS$ requires C, 57·9; H, 5·7; N, 2·9; S, 6·7 per cent).

(*d*) Graded acidic hydrolysis[3] of II removed the benzylidene residue and afforded amorphous methyl

2-acetamido 2-deoxy-α-D-altropyranoside (IV), $[M]_D$ +94° (water), which rapidly consumed 1 mol. of periodate without the formation of formaldehyde or acidic products. (The low optical rotation and rapid periodate oxidation of IV suggest conformational instability[4] of the glycoside.) Thus the acetamido group must be located at $C_{(2)}$ in IV and, assuming normal cleavage[5] of the epoxide ring (that is, to give two axial substituents) in the reaction of I with methanolic ammonia, then II, III and IV must have the D-altrose configuration.

The absence of an *O*-acetyl group in II is surprising; further, Peat and Wiggins[2] reported methyl 2-acetamido 3-*O*-acetyl 4 : 6-*O*-benzylidene 2-deoxy-α-D-altropyranoside, melting point 184°, $[M]_D$ + 179° ($CHCl_3$), to be the major product (54·8 per cent) of the same reaction although full experimental details were not given. Re-investigation of the product isolated by these authors confirmed its identity, since it showed strong absorption at 1,729 cm.$^{-1}$ (*O*-acetyl) and 1,624 cm.$^{-1}$ (*N*-acetyl) in the infra-red, and on Zemplén deacetylation it was converted into II.

Total acidic hydrolysis of II gave crystalline 2-amino 1 : 6-anhydro 2-deoxy-β-D-altrose hydrochloride (V), which had an indefinite melting point, $[M]_D$ − 315° (water). (Found: C, 35·8; H, 6·0. $C_6H_{11}O_4$ N.HCl requires C, 36·4; H, 6·1 per cent.)

Substance V did not reduce Fehling's solution (although the hydrolysate from which it was isolated gave a positive reaction suggesting the presence of the free amino-sugar) and consumed 2 moles of periodate (cf. the results of Van Tamelen *et al.*[6], obtained with 2-amino 1 : 6-anhydro-2-deoxy-β-D-gulopyranose). For comparison purposes it may be noted that 3-amino 1 : 6-anhydro 3-deoxy-β-D-altropyranose hydrochloride[7] and 1 : 6-anhydro-β-D-altropyranose[8] have $[M]_D$ values of − 339° and − 348° respectively. Paper chromatographic analysis, using the organic phase of a butanol/water/acetic acid (4 : 5 : 1) solvent system, of V and the hydrolysate from which it was isolated revealed a single component, with an R_F value similar to that of D-glucosamine, which reacted strongly with ninhydrin, aniline hydrogen phthalate[9] (in the latter case) and ammoniacal silver nitrate[10].

The ease of isolation of 2-amino-1 : 6-anhydro-2-deoxy-β-D-altropyranose hydrochloride recommends it as a suitable derivative for characterization of the parent amino-sugar, 2-amino-2-deoxy-D-altrose.

We are indebted to Dr. D. H. Whiffen for the infra-red measurements. One of us (S. V. V.) thanks the Norwegian Pulp and Paper Research Institute for a grant.

Metamict Tantalite from Western Australia

THIRTY-FOUR years ago, Bowley[1] recorded an analysis of a manganese-bearing tantalum–niobium oxide mineral that had been collected by Mr. R. C. Black at Yinnietharra, Western Australia. In his report, Bowley stated that Simpson was of the opinion that this mineral belonged to either the orthorhombic columbite–tantalite series or to the tapiolite–mossite group of tetragonal minerals, and with some element of doubt the mineral was tentatively identified as manganomossite.

Palache, Berman and Frondel[2] included this mineral in their treatment of the mineralogy of the tapiolite–mossite series, but clearly directed attention to the fact that the true status of the mineral is in doubt.

Type material, very kindly made available to me by Mr. J. C. Hood, director of the Government Chemical Laboratories, Perth, Western Australia, has now been studied. Autoradiographs of polished fragments exhibit weak but uniform radioactivity, and there are no indications of either inclusions, or zonary distribution of radioactive material as reported by Heinrich and Giardini[3] for columbite from an unspecified locality in Canada.

X-ray diffraction patterns of single particles, 0·2 mm. in diameter, exhibit a few reflexions that are considerably streaked out along arcs, whereas the powder patterns exhibit about thirteen lines, all of which are exceedingly faint. If the mineral is heated in a silica tube *in vacuo* at 1,200° C. for 1 hr., the resultant material yields a fine X-ray diffraction pattern that is in conformity with that obtained from a member of the columbite–tantalite series; the strongest lines yielded by the heated material correspond in a general way with those found in films obtained when the unheated material is employed.

This evidence suggests that the Yinnietharra mineral is metamict tantalite and not a member of the tapiolite–mossite series; accordingly, this would appear to be the first record of a metamict member of the columbite–tantalite series.

A more detailed account of the mineralogy of this Western Australia mineral is to be given elsewhere.

Dependence on Oxygen and Temperature of the Sensitivity of Broad Bean Roots to γ-Radiation

MOTTRAM[1] claimed that the effect of ionizing radiation on the growth of bean roots was greater in the presence of oxygen or in the cold (∼ 0° C.). Since then the oxygen effect has been confirmed by Read[2] and shown in a wide variety of materials. No comparable generalization has been established, however, for temperature. Giles, Beatty and Riley[3], investigating chromosome structural changes in

Tradescantia, have stated that radiosensitivity is affected by temperature differently under conditions of aerobic and anaerobic irradiation.

I have attempted to re-examine the problem, using the reduction in the rate of elongation of the primary root of the broad bean, *Vicia faba* (Sutton's Prolific Longpod), as the index of radiosensitivity. All the radiation exposures were carried out in times not exceeding about 20 min., over a range in which the effects depend only on total dose and not on exposure time. The total growth in 10 days after irradiation is approximately linearly related to the logarithm of the radiation-dose of cobalt-60 gamma-rays. The various modifying treatments give regression lines of the same slope, and from the horizontal separation, an estimate of relative potency of a pair of treatments may be obtained, with fiducial limits at the chosen level of significance[4]. All the results are expressed in terms of such ratios of radiosensitivity, followed in brackets by fiducial limits at the 5 per cent level of significance.

Temperature effect. Under conditions of air saturation, radiosensitivity at 1–2° C. is 1·16 (1·29, 1·05) times that at 19–20° C. The amounts of dissolved oxygen at these two temperatures are, reduced to standard temperature and pressure, 10 cm.^{3} and 6·4 cm.^{3} oxygen/litre, respectively. With equal oxygen concentrations (10 cm.^{3}/litre) the ratio of radiosensitivities would be 0·98 (1·10, 0·89). Under anaerobic conditions the ratio is 1·22 (1·32, 1·12). The effect of temperature on sensitivity over this range is thus small, and is not very different for aerobic and anaerobic irradiations.

Oxygen effect. The foregoing data may also be expressed in terms of the aerobic (10 cm.^{3} oxygen/litre)/anaerobic radiosensitivity factor at the two temperatures, namely, 2·80 (3·05, 2·56) at 19–20° C., and 2·42 (2·59, 2·26) at 1–2° C. The similarity of the oxygen effect under two conditions so different as regards metabolism would seem to imply that the mechanism of this effect does not involve metabolic processes primarily.

Bean seedlings may be kept at a temperature of 1–2° C. for considerable periods (weeks) and after restoration to 19° C. they grow at practically the normal rate. Seedlings which are irradiated and then kept at 1–2° C. and later restored to 19° C. show a reduced growth-rate not very different from the normal radiation effect. The radiation injury thus remains latent but undiminished while in the cold (cf. the observations on frogs by Patt[5]). It is of interest to see whether this latent injury can be modified by oxygen; at ordinary temperatures, the enhancing effect of oxygen on radiosensitivity is completed during irradiation.

(1) Seedlings were irradiated at 1–2° C., with saturation aeration, and then oxygen was removed while they were still in the cold, and the temperature was then brought up to 19° C. in about 20 min. while still under anaerobic conditions; other seedlings had full aeration during and after irradiation. The enhancing effect of the oxygen after irradiation was only 1·05 (1·20, 0·92).

(2) Seedlings were irradiated at 1–2° C., with no oxygen present, and then oxygen was added (saturation aeration) while they were still in the cold, and the temperature was brought up to 19° C. in about 20 min.; other seedlings were kept without oxygen during and after irradiation, until the temperature had reached 19° C. The enhancing effect of the oxygen after irradiation was only 1·01 (1·18, 0·86).

Thus the latent injury both with aerobic and anaerobic irradiation is not influenced by oxygen after the irradiation. If oxygen develops direct radiation injury, as suggested by Alper[6], it must act very quickly after irradiation of a target, even in the cold. In any event, it seems that the effect of oxygen on radiosensitivity is not related directly to metabolic processes.

Reaction of Carbon Monoxide with Evaporated Barium Films

Carbon monoxide is one of the more common residual gases found in radio valves and the like, because carbon and oxygen are both present as impurities in the metals used for electrodes. After these impurities have diffused separately through the metal, they combine at the free surface and are desorbed as carbon monoxide[1]. Wagener[2], Morrison and Zetterstrom[3] and, recently, della Porta[4], have shown that the amount of carbon monoxide which is taken up by a barium getter film is much less than that to be expected if all of the barium reacted. This limitation is so marked that the term 'poisoning' has been used by way of description.

Some recent studies of the oxidation of barium[5,6] have shown that in this case also a protective film about 50 A. thick is formed at temperatures less than 35° C. At higher temperatures, the whole of the barium film reacts with oxygen. The existence of a critical temperature above which an oxide layer ceases to be protective is predicted by Mott's theory of oxidation[7]. The behaviour of barium towards carbon monoxide suggests strongly that the so-called poisoning is because the film of reaction product is protective. It is significant that the thickness of the film in the case of carbon monoxide is about the same as that of the protective film of oxide.

An experimental study of the taking up of carbon monoxide by evaporated barium films (from commercial getters) has been made in this laboratory, to discover whether there is a critical temperature above which the barium is not poisoned by carbon monoxide. The experimental methods and the apparatus used were similar to those for the study of the oxidation of barium[6]. The results obtained are now described briefly.

The critical temperature above which the film of reaction product ceases to be protective has been found to be 80° C. Below this temperature, the thickness of the protective film decreases: expressed as the number of monolayers of absorbed gas, the thickness is about 15 monolayers at 20° C. and 20 monolayers at 60° C., that is, about 50 A. Above the critical temperature of 80° C., barium getter films continue to react until they are used up completely: this is shown by their becoming translucent, although stained brown. This staining, and the absence of any change in the slight influence of a nearby ionizing electron discharge upon the speed of pumping of the carbon monoxide (condensation coefficient), suggests that the gas molecules (neutral or ionized) are not taken up directly by the barium, but are first dissociated into oxygen and carbon. Thus the reaction is one of oxidation in the presence of carbon, and so the qualitative similarity between the behaviour of barium towards oxygen and carbon monoxide is to be expected.

In some details, there are important differences between the reactions in the two cases. In the case of oxygen, it was found[8] that the first monolayer of oxygen was only taken up if there were nucleation centres in the surface of the barium film. Ordinarily, such centres always exist in the surface of getter films deposited in a fraction of a minute and at pressures greater than 10^{-8} mm. of mercury. Moreover, during the adsorption of the first monolayer of oxygen the speed of pumping increased. In the case of carbon monoxide, the speed of pumping has been found always to decrease during the adsorption of the first monolayer. Furthermore, no nucleation centres are necessary. Once the first monolayer of carbon monoxide has been absorbed, then the film of reaction products grows in a manner which can be explained with the aid of Mott's theory.

A fuller account of this work is being submitted for publication elsewhere.

I wish to thank Mr. B. M. Cox for help with the experimental work, Mr. M. E. Haine for helpful criticism, and Dr. T. E. Allibone, director of the Research Laboratory, Associated Electrical Industries, Ltd., for permission to publish this communication.

State of Iodine in Sea Water

WATER from the upper layers of the ocean contains some 40 µgm./l. of iodine compounds. Sugawara[1] has shown that about half this is iodide, while the remainder is an oxidized form, which he attributes to iodate. We find that various observations are more readily explained on the hypothesis that the oxidized form is principally hypoiodous acid.

(1) The ratio of oxidized form/iodide is about unity[1]. Calculation from thermodynamic data[2] shows this to be close to the ratio that would obtain between hypoiodous acid and iodide when in equilibrium with atmospheric oxygen, water and hydrogen ions at the *p*H of sea water. (2) It has been observed that sea water exposed to iodine-free air loses its iodine compounds[3]; moreover, the iodine content of the atmosphere near the sea[4] rises to 1–2 µgm./m.^{3}. Data upon the relevant free energies[2] show that this is about the value to be expected if air is equilibrated with sea water containing its iodine principally as hypoiodous acid and iodide in equal amounts. (The hypoiodous acid and iodide take part in an equilibrium to give a trace of iodine which is volatile.) (3) The ratio of total iodine/chloride is higher in warm, partly enclosed sea areas[5]. This is to be expected from the effect of temperature upon the equilibria mentioned in (1) and (2)[2], which results in a marked increase in the content of volatile iodine molecules when sea water is cooled.

Whereas the hypothesis accounts for these findings, it should be noted that iodate and not hypoiodous acid would be the thermodynamically stable form of oxidized iodine in the sea. However, it seems likely that the rate of iodate formation from hypoiodous acid, a third-order reaction in near-neutral solution[6], will be slow at the very low hypoiodous acid concentrations in sea water. Together with assimilation by powerfully reducing biological material this factor will tend to prevent iodate accumulating in the sea. On the basis of the hypothesis, and given the necessary thermodynamic data, it should be possible to predict the final oxidation states of marine materials which undergo rapid oxidation-reduction reactions with iodide and hypoiodous acid or iodine.

This work and the relevant calculations will be presented in greater detail elsewhere.

Colorimetric Estimation of Manganese

TETRAMETHYLDIAMINODIPHENYLMETHANE ('tetrabase') has been widely used for the colorimetric estimation of quantities of manganese of the order of 0·01–0·1 µgm.[1-4]. As generally applied, the test involves the addition of tetrabase and potassium periodate in excess to a sodium acetate–acetic acid buffer containing manganese in solution. The intensity of the transient blue colour[1-3]—or more permanent green[4]—so produced is closely related to the concentration of manganese. The nature of the reaction or of its end-products does not appear to have been elucidated, although it is known that manganese hydroxide reacts with tetrabase to produce a blue colour[5], and it has been suggested that in the presence of periodate, manganese acts as a catalyst in the oxidation of tetrabase[3].

In a preliminary study of the reaction it has been found that permanganate and hydrated manganese dioxide are equally effective in the production of the blue colour in the absence of other oxidizing agents. The concentration of manganese necessary to produce unit increase in colour intensity under these conditions is, however, 30–40 times greater than when periodate is present. When manganese and periodate are present in excess, the molar concentration of tetrabase required to produce the same unit increase in intensity is approximately twice that of permanganate or manganese dioxide. The reaction between permanganate and tetrabase is extremely rapid, whereas in the normal application of the test, where periodate is present, colour development may take several minutes. The tetrabase derivative responsible for the blue colour in aqueous medium can be extracted with chloroform. This solution is colourless and contains no manganese. On removal of the chloroform and addition of water, the blue colour reappears.

These results are in agreement with the suggestion that manganese acts in a catalytic role, tetrabase being oxidized by permanganate or manganese dioxide, and the reduced manganese so produced being re-oxidized by periodate. It is probably this latter reaction which determines the rate of colour development. To account for the quantitative nature of the test, it is clear that the reaction must cease after a certain amount of colour has been produced. With periodate and tetrabase in excess this can only be brought about by the loss of manganese from the system.

If the reaction is carried out at temperatures greater than 90° C., little or no colour is observed, although the blue pigment is quite stable to heat. On cooling, the addition of further tetrabase and periodate is ineffective, and additional small amounts of manganese produce colour intensities much less than those expected. Excess of manganese, however, produces the usual intense blue. It is suggested that in the oxidation of tetrabase a second substance in addition to the blue pigment is formed. This is soluble in water and is capable of complexing manganese, which is then lost from the oxidation-reduction cycle. At high temperature this second reaction is favoured, and this accounts for the inverse temperature-colour intensity relation which has been observed[4].

Although the method in routine use is capable of giving duplicate estimates differing by less than 5 per cent, extinction values per unit manganese may show unaccountable variations from day to day. Such variations are often associated with changes in the rate of colour development which, as has been shown, depends on the manganese oxidation cycle. This is strongly affected by the order in which reagents are added. When periodate is added last, the initial phase of colour development is very slow, the intensity/time curve following a markedly sigmoid pattern typical of an autocatalytic reaction. When tetrabase is added last, however, the initial development is rapid, with no early lag phase, and final intensities tend to be higher.

It has been shown that the oxidation of divalent manganese to permanganate in strongly acid solution is autocatalytic[5], and the results here suggest that a similar mechanism may be operating, the presence of a high-valency state of manganese being necessary for the reaction to proceed at maximum rate. It seems likely that this part of the reaction is responsible for many of the troubles which have been experienced with the test and a fuller understanding of the oxidation of manganous ions to permanganate at extremely low concentrations will be necessary if further progress is to be made in the use of the method.

In the course of this study it was observed that water from a 'Permutit' ion-exchange resin column, if used for making up reagents, may interfere seriously with results. This was in spite of the fact that water from the same column had been used successfully for some years previously. It is probable that traces of resin, which have been observed at a concentration of 3 p.p.m. in this water, were the cause of the interference.

Use of Wooden Boxes for Breeding Mice

As a result of a personal communication made to one of us that the Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine, U.S.A., had reverted to the use of wooden boxes in preference to metal boxes for breeding mice, and had thus restored their previous level of productivity, it was decided to investigate the most suitable pattern of box and its mode of construction.

The box now in regular use at the experimental mouse-breeding unit at Hampstead is made of imported cedar or other suitable hard wood. The internal dimensions are 12 in. long, 8 in. wide and 4¼ in. deep. The sides and ends are ⅜ in. thick with mortised joints reinforced by brass pins; and the bottom is ³⁄₁₆ in. thick resin-bonded 3-ply wood also lined up with brass pins. The parts are held together with a phenolformaldehyde resin, and it is this resin, not the pins, that holds the box together. The resin is resistant to both water and heat. Plywood is necessary for the bottom because it does not expand laterally when wet, as does plain board. Warping will only occur if unseasoned wood is used; this, however, is hard to avoid, but we have found that only about one in twenty boxes gives trouble in this way, and then only if too little resin is used.

The lid of the box is of metal with a built-in basket for cubes, and a small bridge to support an inclined 12-oz. medicine-flat type water-bottle with a protected hole for the passage of the drinking-tube. Any preferred pattern of lid can be used with one proviso. The shoe-box type lid with an exterior flange is unsuitable, for it enables the mice to get at the edge of the wood and gnaw their way out. The lid must fit inside the box, the interior flange going down about ¼ in.; with such a lid gnawing is prevented.

Wooden boxes that have been in use for two years, being regularly sterilized by steam or boiled in water, are virtually as good as new; their lifetime is not yet known but it is certainly long.

A fuller report is being published elsewhere.

FORTHCOMING EVENT

Wednesday, August 7—Friday, August 9

British Society for Research on Ageing (at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 9.30 a.m. daily—Symposium on "The Biology of Hair Growth"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned.

Principal Physicist in the Radiotherapy Department—The Superintendent, Guy's Hospital, London, S.E.1 (August 12).

Senior Lecturer or Assistant Lecturer in the Department of Physics—The Registrar, The University, Manchester (August 12).

Senior Lecturer and a Lecturer in the High Speed Digital Computing Laboratory of the School of Electrical Engineering, New South Wales University of Technology, Sydney, for duties associated with the analysis and programming of problems for the UTECOM computer—The Agent-General for New South Wales, 56–57 Strand, London, W.C.2 (Australia, August 15).

Assistant, Grade B (with a degree in physics, and preferably suitable industrial experience), in Physics—The Principal, Wigan and District Mining and Technical College, Wigan (August 16).

Assistant Lecturer in the field of (*a*) Plant Biochemistry and Nutrition or (*b*) Soil Physics—The Registrar, The University, Nottingham (August 17).

Assistant Lecturer or Lecturer in Electrical Engineering—The Registrar, University College, Singleton Park, Swansea (August 17).

Assistant Lecturer or Lecturer in Physics—The Registrar, The University, Sheffield (August 17).

Assistant Lecturer in Theoretical Physics—The Secretary, Birkbeck College, Malet Street, London, W.C.1 (August 20).

Assistant Lecturer or Lecturer in Veterinary Physiology—The Registrar, The University, Liverpool (August 20).

Lecturer in Geography, with special reference to regional and social geography—The Secretary, Birkbeck College, Malet Street, London, W.C.1 (August 24).

Deputy Librarian at Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, August 31).

Post-Doctoral Fellow in Physical Chemistry, for research work connected with the application of electron magnetic resonance spectroscopy to a study of free radicals—The Deputy Registrar, The University, Edgbaston, Birmingham 15 (August 31).

Research Assistant (honours graduate in chemistry or agricultural chemistry), for research on the chemical and physical properties of expanded vermiculite in relation to its use in agriculture—The Registrar (Room 9 O.R.B.), The University, Reading (August 31).

Senior Lecturer in Mathematics—The Registrar, The University, Stellenbosch, South Africa (August 31)

Lecturer in Geology; and a Lecturer in Pharmacy at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, September 1).

Lecturer (with special qualifications for teaching and research in inorganic chemistry) in Chemistry—The Registrar, The University, Edgbaston, Birmingham 15 (September 1)

Lecturer in Poultry Science in the Faculty of Rural Science—The Acting Registrar, University of New England, Armidale, N.S.W., Australia (September 13).

Chair of Mathematics at the Pietermaritzburg or Durban centres of the University of Natal, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, September 14).

Senior Lecturer or Lecturer (preferably with qualifications in mycology or physiology with special reference to the lower plants) in Botany at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 28)

Senior Lecturer (with an honours degree or higher degree in mechanical engineering) in Mechanical Engineering at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 28).

Professor of Applied Mathematics in the Durham Division of the University—The Registrar, University Office, 46 North Bailey, Durham (September 30)

Senior Lecturer (Clinical) in Tropical Medicine at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 30).

Chair of Applied Mathematics—The Registrar, University College of Wales, Aberystwyth (October 7)

Assistant Lecturers and Lecturers in Engineering in the Departments of Civil, Mechanical, Electrical and Mining Engineering—The Registrar, The University, Nottingham.

Medical Entomologist (with qualifications in entomology and experience in insect and malaria eradication control) with the Government of Jamaica, for duties in connexion with malaria control—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.117/32/025.

Research Assistant (with an honours degree and some experience of stress analysis and properties of materials) for research into expanding tubes in high pressure boilers—Prof. H. Ford, City and Guilds College, London, S.W.7.

Technician in the Genetics Research Laboratory, to assist in research employing physiological and serological techniques and histology—The Secretary, The University, Old College, South Bridge, Edinburgh.

The Unitherm Drier

By designing the Unitherm Drier on the same principle as a coupled heating and ventilating system our designers met the need for an efficient laboratory cabinet that gives rapid, uniform drying. It has a capacity of 100 trays of 400 grams of material of D.M. content 20%. It conforms to strict laboratory needs and has been carefully tested under actual working conditions, at controlled working temperatures up to 105° C.

Full details are given in our leaflet No. 24 and a comprehensive survey of our other products and services is given in booklet No. 14.

HIGHER TECHNOLOGICAL COURSES

Lecture Courses.

"Nuclear Chemistry and the Application of Radionuclides to Chemical Problems": 12 lectures on Tuesdays at 7.30 p.m., commencing September 24, 1957.

"Modern Aspects of Chromatography": 10 lectures on Fridays at 7.30 p.m., commencing October 11, 1957.

"Modern Chemistry and Metallurgy of Some Rarer Metals": 6 lectures on Wednesdays at 7.30 p.m., commencing October 30, 1957.

Lecture and Laboratory Courses:

"Some Aspects of Radiochemistry": 24 sessions on Tuesdays, 6.30 to 9.30 p.m., commencing November 7, 1957 (provisionally).

"Some Aspects of Biochemistry": 36 sessions on Fridays, 6.30 to 9.30 p.m., commencing September 27, 1957.

"Modern Chemistry of Oils and Fats": 36 sessions on Wednesdays, 6.30 to 9.30 p.m., commencing October 2, 1957.

"The Recent Chemistry and Physics of Waxes", 36 sessions on Thursdays, 5 to 9 p.m., commencing October 3, 1957.

"Some Aspects of Microbiology": 36 sessions on Tuesdays, 6.30 to 9.30 p.m., commencing October 1, 1957

"Chromatography" Short full-time courses in Paper Chromatography and Ion Exchange held at frequent intervals

Full particulars from the Principal.

C. E. GURR, M.Sc., Ph.D.,
Secretary to the Education Committee.

NORTHERN POLYTECHNIC

Session 1957-58

ADVANCED COURSES IN

ELECTRONICS AND MICROWAVE PHYSICS

ELECTRICAL DISCHARGES IN GASES

SOLID STATE PHYSICS

Suitably qualified students can proceed to the M.Sc. Degree of the University of London. Session commences September 23, 1957

Also Short Lecture Courses on:

INTRODUCTION TO ELECTRONICS AND MICROWAVE PHYSICS—commencing October 2, 1957.

(This is designed for graduates requiring basic electronics for industrial applications)

TRANSMISSION LINES—commencing October 2, 1957

MATHEMATICS OF CIRCUIT ANALYSIS—commencing October 2, 1957.

WAVE-GUIDES—commencing November 6, 1957.

AMPLIFIERS—commencing November 6, 1957.

Inquiries should be addressed to:

Head of Department of Physics,
NORTHERN POLYTECHNIC,
HOLLOWAY, LONDON, N.7
(Telephone: NORth 1686)

THE POLYTECHNIC

309 REGENT STREET, W.1

DEPARTMENT OF MATHEMATICS AND PHYSICS

The following courses of lectures have been arranged, starting in September, 1957:

1. MATHEMATICAL STATISTICS, on Tuesday, Wednesday, Thursday, and Friday evenings.
2. ADVANCED MATHEMATICS FOR SCIENTISTS AND ENGINEERS, on Friday evenings.
3. MODERN ELECTRIC NETWORK THEORY, on Friday evenings.
4. FINITE DIFFERENCE EQUATIONS (12 lectures), followed by ORDINARY DIFFERENTIAL EQUATIONS (15 lectures), on Tuesday evenings.
5. INTEGRAL EQUATIONS AND GREEN'S FUNCTIONS, on Wednesday evenings.
6. AUTOMATIC DIGITAL COMPUTERS, on Tuesday evenings

Full particulars may be obtained on application to the Director of Education

CHELSEA POLYTECHNIC

(College of Advanced Technology)

MANRESA ROAD, S.W.3

DEPARTMENT OF CHEMISTRY

Session 1957–58

A course of 20 postgraduate lectures on "Biochemistry" (to be arranged in four groups) will be given by Dr. E. M. Crook, M.Sc., A.R.I.C., and Professor F. L. Warren, M.A., D.Sc., on Mondays, 7.15 to 8.30 p.m., during the period October 7, 1957, to March 17, 1958. The course is designed for students who possess a knowledge of chemistry to degree standard. Fee: £2 for whole course or 10s. for each group

A leaflet giving details is obtainable from the Secretary.

CHELSEA POLYTECHNIC

(COLLEGE OF ADVANCED TECHNOLOGY)

DEPARTMENT OF CHEMISTRY

SANDWICH COURSE IN CHEMISTRY

The Sandwich Course in preparation for the examinations leading to Graduateship of the Royal Institute of Chemistry commences in January, 1958. The course (works based) is of four years' duration and involves six-months' study at College each year. The normal requirements for admission to the course will be successes at A Level (G.C.E.), or comparable examinations, in chemistry, together with physics and/or mathematics and three suitable ordinary level subjects

Inquiries from industrial firms, research organizations, and government departments will be welcomed. Particulars from the Secretary, Chelsea Polytechnic, Manresa Road, S.W.3

OFFICIAL APPOINTMENTS

MASSEY AGRICULTURAL COLLEGE

(UNIVERSITY OF NEW ZEALAND)

PALMERSTON NORTH, NEW ZEALAND

LECTURESHIP IN PHYSIOLOGY OF THE SHEEP

Applications, closing November 15, are invited for a Lectureship on the staff of the Sheep Husbandry Department, the appointee to lecture on the physiology of growth and reproduction in sheep and beef cattle. Salary £1,025 to £1,275 or £1,315 to £1,615 according to experience and qualifications. Commencing salary at any point within these scales according to qualifications. Applicants should possess degrees, preferably higher, in either agricultural, veterinary or pure science

For conditions of appointment and memorandum, giving further particulars, apply by airmail to the Registrar, Massey Agricultural College, Palmerston North, New Zealand.

QUEEN MARY COLLEGE

(UNIVERSITY OF LONDON)

MILE END ROAD, E.1

Chemistry Graduate required for research in Chemistry Department to work on problems of physical-organic chemistry with particular relation to organo-phosphorus compounds. The appointee will normally be expected to proceed to the Ph.D. degree. Remuneration within the range of £400 to £450 per annum

Applications to the Registrar, Queen Mary College, London, E.1.

UNIVERSITY OF THE WITWATERSRAND

JOHANNESBURG, SOUTH AFRICA

Applications are invited for appointment to the post of Professor of Mechanical Engineering who is Head of the Department of Mechanical Engineering. Duties are to be assumed on January 1, 1958, or as soon as possible thereafter. The substantive salary attached to the appointment is on the scale £1,950 by £50 to £2,250 per annum. A married man will also receive a temporary cost of living allowance which is at present at the rate of £234 per annum. In addition the substantive salary will be augmented by subvention from outside sources in the form of a non-pensionable allowance which will guarantee an inclusive substantive salary at the rate of £2,500 per annum until the end of 1963. Membership of the Provident Fund is compulsory. Membership of the Staff Medical Aid Fund is compulsory in the case of an officer who is found eligible for such membership.

Applicants are advised to obtain a copy of the information sheet relating to the above vacant post from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close in South Africa and London on August 31, 1957

UNIVERSITY OF MANCHESTER

Applications are invited for a post in the Department of Physics at one of the following grades: Senior Lecturer or Assistant Lecturer. The salary scales are as follows: Senior Lecturer, £1,700 to £2,050 per annum; Lecturer, £900 to £1,650 per annum; Assistant Lecturer, £700 to £850 per annum. Initial salary and status according to qualifications and experience. Membership of F.S.S.U. and children's allowance scheme.

Applications should be sent not later than August 12, 1957, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained.

SCUNTHORPE HOSPITAL MANAGEMENT COMMITTEE

(50 BEDS)

LINCOLNSHIRE RADIOTHERAPY CENTRE

MEDICAL PHYSICIST

Immediate vacancy in expanding department including developments connected with rotational therapy and radioactive isotopes. The appointment may be into either the Senior Grade or Basic Grade according to qualifications and experience. Salary scale Basic grade probationary period £525 by £25 to £625 (for first- or second-class honours) afterwards £650 to £845; Senior Grade £910 by £40 to £1,230.—Form of application from Group Secretary, War Memorial Hospital, Scunthorpe, Lincs.

UNIVERSITY COLLEGE OF SWANSEA

Applications are invited for the post of Assistant Lecturer or Lecturer in Electrical Engineering. Salary: Assistant Lectureship in the range £700 to £850 per annum; initial salary according to age and qualifications. Lectureship, £900 to £1,650 per annum (only in an exceptional case will the initial salary be more than £1,100). F.S.S.U. benefits and family allowances.

Further particulars may be obtained from the Registrar, University College, Singleton Park, Swansea, to whom applications must be sent by August 17, 1957.

UNIVERSITY OF MANCHESTER

Applications are invited from graduates for the post of Assistant Lecturer in Psychology. Candidates should have special interests or training in experimental and statistical psychology. Salary on a scale £700 to £850 per annum with membership of the F.S.S.U. and children's allowance scheme.

Applications should be sent not later than August 10, 1957, to the Registrar, the University, Manchester 13, from whom forms of application and further particulars may be obtained.

UNIVERSITY OF SOUTHAMPTON Applications are invited for the post of Lecturer or Assistant Lecturer in Biochemistry in the Department of Physiology and Biochemistry. Salary scale £900 by £50 to £1,350 by £75 to £1,650 for Lecturer and £700 by £50 to £850 for Assistant Lecturer, with placing on scale according to qualifications and experience. F.S.S.U. and children's allowances. Higher degree in biochemistry or physiology essential.—Further particulars should be obtained from the Secretary and Registrar, to whom applications (six copies), should be sent not later than September 7, 1957.

Elementary Theory of
ANGULAR MOMENTUM

by

M. E. ROSE

(Chief Physicist, Oak Ridge National Laboratory)

A JOHN WILEY BOOK

Based on a series of lectures given at the Oak Ridge National Laboratory, the theory of angular momentum is here presented as simply as possible. The value of the book lies in the clarity of presentation. It is the author's conviction that a clear understanding of the elements of the theory can be helpful to many physicists and that anyone with a knowledge of quantum mechanics can master the ideas.

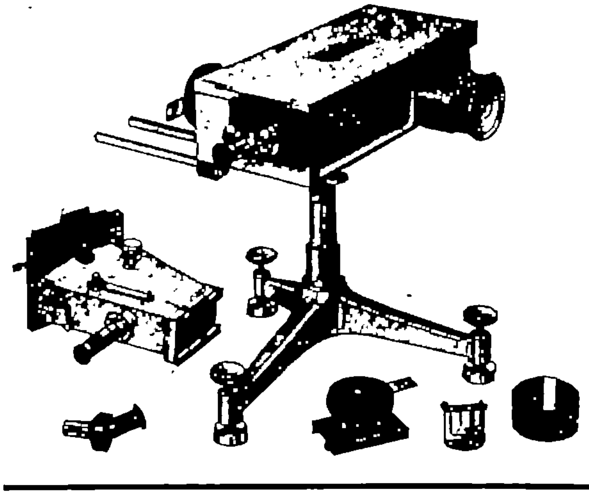
PRECISION INSTRUMENTS

Direct Reading Wavelength Spectrometer



for use in the visible spectrum and also, when required, in the ultra violet and infra red. Reading in wavelengths directly.

A camera attachment can be supplied giving the following length of spectrograms:

With quartz prism, wavelength 10,000 A. to 2,200 A., 70 mm.

With glass prism, wavelength 10,000 A. to 3,600 A., 125 mm.

A large range of accessories can be supplied with this spectrometer, making it a really universal instrument, and our staff will at all times be pleased to recommend the equipment most likely to meet special requirements.

TREATMENT OF THE MENTALLY ILL

MENTAL illness is so disturbing and unexpected that it is inevitable that it should arouse an emotional response. This is particularly evident in primitive and uneducated people. The earliest historical reaction seems to have been the view that insanity was due to possession by devils. Hallucinations, which cause the patient to reply to 'voices', and delusions, particularly of persecution, would seem to confirm such a conclusion. It may be that the trephining operation in which palæolithic man removed, with what pain we cannot conceive, sections of a living man's skull, was designed to let out the devils which had somehow become lodged in the head.

The next stage in such a belief was that the patient had suffered from a divine intervention. He was 'touched' by God, just as the brain of the paralysed had undergone a 'stroke' by the same hand. Possibly the wild prophecies and fantastic delusions of some paraphrenics would support such an idea. In some beliefs, for example, the Moslem, the insane are still regarded as possessing holiness.

However, a certain number of mentally ill patients, in spite of the idea that their illness had a divine origin, are definitely dangerous, and many are a nuisance, interfering with the lives and work of ordinary folk. We can imagine the practical man having his say and insisting that these people be restrained. Indeed, in Biblical times, insane people were sometimes chained in caves and dependent on charity for their food, or died if it were not provided. This may be regarded as the beginning of what has been euphemistically called 'custodial treatment'—but which really means shutting the patient up so that he is no longer a danger or a nuisance. They were confined in cells, loaded with arm and leg irons, bled, purged, flogged, and if females seduced, in appalling conditions.

In 1792 Pinel commenced the modern era by removing the patients' shackles in France, and simultaneously Fricke in Germany and Tuke in England started similar reforms. From this time physicians tried to treat their patients, and not merely confine them to a place of safety. Treatment meant understanding the illness. The time of the great classifiers, such as Kraepelin, arrived, and insanity was differentiated from dementia and mental deficiency. Psychiatrists were then beginning to speak the same language.

Better than this, once one case could be distinguished from another (and not merely labelled 'insane') treatments could be discovered, developed, and generally applied. This has finally given us such therapy as insulin, which doubles the recovery-rate of schizophrenia, electrical convulsive therapy which does the same thing for depressives, and so on. The new chemical tranquillizers offer wonderful hopes of reducing the violent, dangerous patient to a sociable, human being.

To turn from the bright hopes which we entertain for the future of psychiatric medicine to the legal position comes almost as a mental shock. The recent report* of the Royal Commission on the laws relating to mental illness and mental deficiency shows that the legal aspects of these disorders are still of importance to the community. It is impossible here to go minutely into the Commission's conclusions, but broadly they diminish the obsolete custodial treatment and the excessive safeguards against wrong certification (which are now unnecessary), and make it easier for voluntary treatment and discharge of recovered patients. In practice, the average psychiatrist rarely certifies anyone, so many will go willingly for treatment, and the scarcity of beds leads to patients being discharged too early rather than to their being unduly detained.

It will be, however, easier to persuade patients to go for treatment, and the mental hospital will lose the residue of the 'stigma' left from the past. The Commission is, therefore, to be congratulated on its labours, and it is hoped that its conclusions will soon become law.

But the law is static: it is banal to say that one cannot heal people by passing statutes, although one can hinder the physician in his work by them. It is not legislation but research and more research which we need. Schizophrenia, that terrible 'cancer' of the mind, is still a mystery. A large majority of the beds in mental hospitals are occupied by schizophrenics and, in spite of modern treatments, those who have been there for any length of time tend to remain most of their life. Manic-depression is not so crippling as schizophrenia but forms a recurring menace, a suspended sword over the patient's head, since he never knows when he may be ill again. The basic cause of these illnesses is still a mystery and its discovery as important as the cause of cancer.

Many organic mental illnesses can now be treated: the syphilitic diseases of the brain have been conquered by penicillin and medical adjuvants, cerebral tumours now yield more to operation, trauma such as that produced by boxing and motor-car accidents is better understood and sometimes preventable; but the functional mental illnesses (without obvious organic basis) still need elucidation.

The Commission rightly directs attention to patients suffering from a psychopathic personality, who so often come into contact with the law, and indeed form a considerable percentage of the prison population. It offers suggestions for disposal and treatment. This is an improvement on the senseless recurrent sentences on men who are not quite sane and not quite insane, the useless judicial admonitions to prisoners who cannot, by their very mental structure, benefit from them, and the eventual release of sick men who will inevitably receive further sentences without any attempt to understand or treat them.

---

* Report of the Royal Commission on the Law Relating to Mental Illness and Mental Deficiency, 1954–57. Pp. x+306. (Cmnd. 169.) (London: H.M. Stationery Office, 1957.) 10s 6d. net.

If it were asked along what lines research should be extended, it might be suggested that the problem is too great for individuals, no matter how devoted or industrious. What is needed is team work: the collection of data from every point of view. Heredity, parental personality, family life, upbringing, development, and complete knowledge of the patient's environment. The individual physique with the physical investigation must form a part, but only a part, of the research. It must never be forgotten that human beings have minds and react mentally as well as physically. Too often in the past has the physical side of mental illnesses been regarded as a respectable area of investigation, whereas the psychological side has been neglected.

The Commission has recommended that the old Board of Control should be abolished as being obsolete. It might well be replaced by a modern Mental Research Council, to suggest, assist financially, and co-ordinate work on this terrible disease.

PEACEFUL USES OF ATOMIC ENERGY

Proceedings of the International Conference on the Peaceful Uses of Atomic Energy

Held in Geneva, 8 August–20 August, 1955. Vol. 1: The World's Requirements for Energy. Pp. xi+479. 8 dollars; 57s.; 34 Swiss francs. Vol. 6: Geology of Uranium and Thorium. Pp. x+825. 9 dollars; 63s.; 39 Swiss francs.
(New York: United Nations; London: H.M. Stationery Office, 1956.)

THE first volume of the Proceedings of the Geneva Conference is devoted to a very full survey of the world's total energy requirements up to 1975, followed by a further assessment to the year 2000. There are a number of general survey papers, followed by papers from thirty-six countries, setting out their individual needs, so that for many years to come this volume will be consulted by many who want a broad or a detailed picture. Many of the papers trace the rise of industrialization expressed in terms of the harnessing of energy over the past century and try to foresee the future based on the pattern of the past. All scientists are aware of the difficulties they run into in doing this and many of the papers are written with great caution. It will be interesting to consult this volume every few years to see how far the best laid plans have gone astray. Writing two years after the British nuclear energy plans were published, I find our own prophecies are only out by a factor of three in this short time. There may therefore be great surprises in store with regard to the prophecies made even up to 1975, let alone the distant forecasts to A.D. 2000.

The United Nations Department of Economic and Social Affairs has presented here a world review of energy production and requirements. It is rather surprising that the total consumption per capita of energy varies by a factor of only thirty between the under-developed countries, such as India, Pakistan, etc., and the industrialized American giant, but much of this energy is not electrical, and as nuclear energy appears at present to be merely another fuel to be used for the generation of electricity, a more telling ratio is the 5 kWh. of electricity consumed per annum per capita in Pakistan (15 kWh. per capita in India—there are errors of a few 'millions' in Bhabha's paper) and 3,000 kWh. per capita in the United States. Where is the vast increase of electrical energy to come from if the under-developed countries are ever to rise to industrialized nations? The hydro-electric potential of India when fully harnessed can only deliver a total amount of energy about one-seventh of that at present obtained from the burning of cattle dung. If India were to burn coal sufficient to produce the United States per capita consumption of electricity for her population, her coal reserves would disappear in a decade. Neither dung nor coal can help India in the long run, but her uranium and thorium would suffice for more than a century. As Philip Sporn writes: "The very prospect of the achievement is enough to inspire and excite men and nations to efforts at improvement which can have consequences hard to foresee".

The detailed analyses of the many countries present a very diverse picture of the likely use of nuclear energy in the next fifty years. Many countries have fuel reserves adequate for many decades and can see only marginal use of nuclear power unless its cost falls below the cost of generation from coal, oil or hydro-electric plants. Australia, for example, foresees the use of nuclear stations for remote areas to which the cost of bringing coal or high-voltage transmission lines would be high. Canada can foresee the need for a few fairly large stations twenty years hence, and, in the far north, a number of small stations; but the twentieth century is not expected to see extensive generation of electricity in Canada from uranium sources. China, on the other hand, with immense sources of water-power and coal, believes that nuclear stations will supply half her power requirements by the year 2000; the United Kingdom will almost certainly be supplying almost all her needs in like manner by that date. Japan has thin coal seams, difficult to mine, although total reserves are considerable, and in spite of a potential water supply three times the present harnessed figure she fears a serious unbalance between demand and supply before 1975, and, indeed, many other countries can see no solution to their energy requirements by the end of the century other than through nuclear power. The Russian general and detailed plans are conspicuous by their absence from this volume.

The United States are in a very special position. Coal reserves appear to be adequate for a few thousand years, oil and natural gas still supply more than half the total energy expenditure, 98 per cent of houses and farms have electric power, and she leads the world in per capita electric consumption, so the conclusion is justified that for some long time to come the effect of nuclear power on the home and on medium-sized industrial plants is likely to be negligible. Perhaps in the case of very large industrialized consumers with high load factors nuclear power may become important sooner. Her analysis, therefore, of the situation can afford to be more critical and based almost only on competitive costs which differ somewhat with the siting of power stations, although throughout the whole country generation costs are below 8 mills/kWh. and average half of this. Her experts consider that amortization charges and insurance rates should be assessed higher than for conventional power stations, that life-time load factors of very high value should not be assumed because of the expected rapid improvement in nuclear stations and therefore of obsolescence of the early reactors; but against this the estimated capital cost of large reactors is only 50 per cent higher than the cost of coal-fired stations and is expected to fall appreciably in the second generation of construction. The general result is that her approach is more experimental than in Britain; several large power reactors of different design are being built in parallel to permit study of the technical and engineering problems of each reactor and to assess operating and maintenance costs, but no rapid expansion is foreseen (except in medium-powered naval propulsion reactors, which, unfortunately, are not analysed at all in this volume). After a ten-year period the large-powered nuclear station may be competitive in the eastern half of the United States, and in the last quarter of the century America expects that nuclear power will be assuming a dominant role.

One fault of the Geneva Conference is brought out in this volume: there was no time for the refereeing of papers, with the result that some are far too long and there is much repetition, but the whole account is fascinating in the extreme and will be of historical importance.

How much uranium do we need and how much is there available? What we need depends on the degree to which we can convert uranium-238 to plutonium, and thorium to uranium-233. If we can burn up eventually 33 per cent of naturally occurring uranium, one ton of it is equivalent to a million tons of coal, so a few hundred tons of uranium per annum, a figure which includes an inventory for new stations, will suffice for Great Britain to the end of the century. Volume 6 collects the evidence as to abundance of uranium, and in spite of this element being almost the least common element on the Earth the amount, even in concentrations of 2 lb. to the ton of ore, is enormous. Thorium occurs in concentrations of 10 per cent in the monazite sands of India and Brazil. Commercial uranium ore is largely based on the lower limit that will be purchased in terms of metal content, and in America the present limit is ore containing 0·1 per cent uranium oxide. At lower concentrations there are huge reserves and ultimately astronomical reserves in the ocean, which contains one part in a million of uranium. The uranium-producing nations of the West (and again it should be noted that the U.S.S.R. has made no contribution to this volume of information on the geology of uranium) are estimated to have reserves of more than a million tons, which can be produced at 10 dollars per lb. of oxide, and far more than this in the 30–50 dollars per lb. region. It is stated that although new chemical extraction processes will be developed there is no longer a wide margin between the costs of modern plant and the results which are theoretically possible. This is because of the great technological drive which has been put into the extraction process in a decade.

The main review of the natural occurrence of uranium and thorium is followed by detailed reviews of seventeen countries, and then follow sixty papers from the United States on the geology of different regions. Perhaps this is justified in view of the fact that the expansion has all occurred in such a short time, and maybe this information is not to be found in the specialist journals, but it seems wrong that an International Conference should publish so many contributions from one source, however informative they are in detail.

The papers on prospecting for uranium and thorium are drawn almost entirely from United States and British sources. The intensified prospecting for uranium after the War has been greatly assisted by a wider range of technical methods than ever available in earlier years, but writers emphasize that successful discovery is still generally based on the application of fundamental geological knowledge. The new aids are, of course, primarily based on Geiger and scintillation counters detecting gamma-rays; local surveys are made on foot, regional by car, and thousands of square miles by light aeroplane or helicopters flying at a few hundred feet at most above ground over tracks a quarter of a mile apart. These surveys can detect oxide of general concentration of 0·001 per cent and the regional air surveys have been of particular importance in locating new areas not previously known to contain uranium. These areas are then surveyed in detail from the air and iso-radioactivity contour maps have been compiled for detailed study on foot or by car. Car recording at 30 m.p.h. can detect 0·001 per cent oxide at a distance of 50 ft. Canada reports that there are more persons searching for uranium to-day than for any other metal, and large deposits averaging 0·1 per cent uranium oxide are regarded as worth mining. A base price is about 3 dollars per lb. of oxide.

Some interesting botanical methods of prospecting for uranium are described by the United States Geological Survey. Vanadium, uranium and selenium occur together in certain of the ores of the Colorado Plateau and a correlation was observed between the distribution of selenium-indicator plants and the uranium–vanadium ore carnotite. These plants have tap roots up to ten metres in length and with favourable distribution of ore the plant thrives, so that plant distribution plotted directly on maps or determined from photographs provides a rapid and inexpensive preliminary survey.

T. E. ALLIBONE

COMMUNICATION THEORY

On Human Communication

A Review, a Survey, and a Criticism. By Dr. Colin Cherry. (Studies in Communication.) Pp. xiv+333. (Cambridge, Mass.: Technology Press of Massachusetts Institute of Technology; New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1957.) 54s. net.

In this book (which is the first of a series entitled "Studies in Communication", edited by W. N. Locke, L. L. Beranek and R. Jakobson), Dr. Cherry treats of the many facets of modern communication theory—among other things, with its impingements upon linguistics, electrical engineering, human physiology and psychology.

It is a little difficult to see to just what audience the book is directed. Dr. Cherry himself states clearly (p. 3) that the book is written for the 'general reader', and its unusually colloquial style would certainly lend some support to the view that it is. But this reader is assumed to be willing and able to follow the mathematical argument of the chapters on signal analysis and the statistical theory of communication, although unacquainted with the elements of linguistics, logic and psychology. It is indeed clear that the book will be of most value to someone trained in the physical sciences, wishing to be introduced to studies in communication.

The task Dr. Cherry has set himself is probably too great for any single writer and, although he has made a bold attempt to deal with those fields in which he is not himself a specialist, the treatment of problems in applied psychology seems one-sided and there are few—and passing—references to physiological studies. It is, no doubt, understandable that Dr. Cherry, who has made noteworthy contributions to the study of hearing, should concentrate his attention on speech, hearing and language. But to do this is not to give a complete description of the field of human communication, and it is unfortunate that Dr. Cherry has not felt himself able to include, for example, some treatment of neurophysiology and the psychology of vision.

Within his boundaries the author has, however, completed a general survey which is always competent and, in some places, stimulating. All the chapters are well documented—indeed, the book would be worth reading for its references alone. It is well presented, for an American book of 1957 not perhaps too expensive, and there are remarkably few misprints (though several seem to have coincided in "Eugène Onĕgin", p. 39, line 6).

There is one thing for which Dr. Cherry deserves great praise: he is almost unique, among the many natural scientists who to-day write about language, in that he really has tried to familiarize himself with the views on language current among specialists in it—that is, among philologists. In this field, Dr. Cherry shows himself a good disciple of that distinguished philologist, Prof. Roman Jakobson.

Some will find cause for regret in the fact that Dr. Cherry has devoted so much space to the discussion of two of the three theories which are fast becoming a plague to the straightforward philologist—those associated with the names of Jakobson, Zipf and Swadesh, respectively. In each of these three cases, what the philologist is worried about to-day is, first, whether the theory is true, and secondly, if it is, whether it is profound or obvious. Those who adhere to the theory of Swadesh will wonder why Dr. Cherry does not mention this, too.

In the book there are, unfortunately, a number of remarks in which lack of clarity or over-generalization gives ground for criticism. We select three linguistic examples: (1) "the establishment of regular syntax [of Ancient Egyptian]" (p. 32)—but presumably the syntax of all languages at all periods is equally 'regular'; (2) "in tone languages, each syllable has either a high or a low tone" (p. 33)—this can clearly only be true of tone languages with two tones (a small minority); (3) "Speech . . . has a most loose grammatical structure" (p. 78)—whatever may this sentence mean?

The glossary of technical terms (pp. 303–7) will be useful, but some of the entries are not helpful; thus, for example, "DESCRIPTIVE SYNTAX. The SYNTAX of historical, ordinary languages"—if any meaning is to be attached to the two defining adjectives, presumably all languages are equally historical and equally ordinary—that Tahitian seems 'extraordinary' to an Englishman is quite irrelevant. And why is there no entry here for the word *prosodic* (p. 94, line 3)? This word, very fashionable in 'London' linguistics, is not intelligible to the 'general reader' (nor, indeed, to the two reviewers).

HORMONES IN GESTATION

Gestation

Transactions of the Third Conference, March 6, 7, and 8, 1956, Princeton, N.J. Edited by Prof. Claude A. Villee. Pp. 253. (New York: Josiah Macy, Jr. Foundation, 1957.) 4.75 dollars.

HORMONES are produced during pregnancy by the maternal organism, the fœtus proper and the placenta, but their function is not easy to define, at any rate quantitatively, and their subsequent metabolism and interactions are exceedingly difficult to follow, let alone to interpret.

The members of this conference on gestation began by considering the maternal hormones. Some of these, such as the steroid, progesterone, have been well characterized chemically, and this hormone is one of those which are necessary for the maintenance of pregnancy, although how it does so is still unknown. Others, such as 'relaxin', are of a protein nature; and although some of the effects of this substance were described in 1926 and there is evidence that it is active in human pregnancy, it has been little investigated. Its assay is biological and few improvements have been made in this since it was first described. Remarks such as these might be made about more of the hormones known to be released during a successful gestation, but unfortunately there are other hormones and problems about which we have also got more literature than knowledge. Insulin is a good example. Does it cross the placenta? Does pregnancy mitigate maternal diabetes? Why are the children of diabetic women so large? We just do not know.

The hormones produced by the placenta were next given a good deal of attention. There appear to be a number of these steroids—progesterone among them—and they continue to be liberated by placentæ perfused through the umbilical vessels. This raised the question as to whether the normal destination of these hormones is the mother or the fœtus, but the matter had to be left unsettled.

Improvement in operative technique will no doubt allow the ductless glands of the fœtus to be studied by the classical methods of removal and substitution therapy. The ingenious and cleverly carried out experiments of Wells and Jost have made a start in this direction, but it still seems a little crude to have to tie off the whole head except the lower jaw to exclude the pituitary gland. One wonders whether any of the results obtained are solely due to the lack of a hormone and, if so, of which of the hormones normally secreted by the gland. Nevertheless, the effects described by Jost make very stimulating reading. Dorothy Price opened a discussion on the effect of hormones on sex differentiation in explanted tissues. This technique seems to have an interesting and promising future, but the interpretation of the results will never be easy.

Emphasis has been laid upon the difficulties of this subject, and simplification of the problem cannot be expected in the account of a Josiah Macy conference, for the proceedings are always reported verbatim. Even the opening speakers are interrupted, and the ensuing arguments and interjections are often somewhat chaotic and may be very irritating to the seeker after knowledge. Nevertheless, there is a great deal of real information in this book in spite of the sense of difficulty and ignorance which pervades the whole issue. Great though the men may be who pioneered so triumphantly the promotion and control of atomic fission, perhaps they had a simpler problem to solve than these biologists. R. A. McCance

IMMUNOLOGY: RESEARCH AND TEACHING

Lectures in Immunochemistry

By Prof. Michael Heidelberger. Pp. x+150. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1956.) 4 dollars.

Fundamentals of Immunology

By Prof. William C. Boyd. Third edition, completely revised and rewritten. Pp. xiv+776. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1956.) 10 dollars.

Immunology and Serology

By Prof. Philip L. Carpenter. Pp. viii+351. (Philadelphia and London: W. B. Saunders Company, 1956.) 45*s*. 6*d*.

IMMUNOCHEMISTRY, as Kabat and Mayer wrote in 1952, "has of recent years become a discipline in its own right due largely to the development of precise analytical chemical methods for measurement of both antigens and antibodies". No one has done more than Heidelberger in this development of precise methods; the extent of his contribution can be gauged from the number of times that his work is quoted in Boyd's "Fundamentals of Immunology". He has now published six lectures given in Tokyo in 1955, together with three others. On the whole, the book is disappointing, whether as a review of the development of immunochemistry, of Heidelberger's own work or of the present state of immunochemistry. It gives no indication of the extent to which the work on proteins, particularly that of Svedberg, prepared the ground during the 1920's for the view that antibodies are distinct proteins present in antisera in measurable amounts. Although the book includes a chapter on the relations between chemical constitution and immunological specificity, Landsteiner is nowhere mentioned, although his work beginning before 1917 had been the chief influence in dispelling hazy ideas about specificity.

The presentation of the present state of the theory of the formation of precipitates is incomplete. Once it was agreed that antibody molecules have more than one combining site or 'valency', it was obvious that antibody and antigen, if present in suitable ratios, would build up aggregates held together by specific bonds. But that is not the whole story; for this specific aggregation does not account for the formation of precipitates in extreme antibody excess, and it is not altogether certain whether it, alone, accounts for the formation of precipitates at all.

Boyd's book is "an introduction to the science of immunology". The subject of its first half may be regarded as immunochemistry; that is, the nature of the substances involved in immunity and their interactions. It gives a full and fair account of modern knowledge; its length is justified by the need to know the substances involved and how they behave in order to understand the reactions in the living animal. Boyd now accepts the proofs that antibodies may have more than one valency, and that antigens and antibodies may build large aggregates linked by specific valencies. But his pp. 336–342 still include equations—relating the antibody/antigen ratio in the precipitates to proportions in which antibody and antigen are mixed—that assume that antibody is univalent; equations also that, unlike that of Heidelberger and Kendall, include arbitrary parameters, and do not express some of the most characteristic features of the precipitin curve.

The second part of the book is more clinical and deals with such subjects as hypersensitivity, autoimmunization and disease and immunity in action. As is inevitable when such a wide field is covered, any reader may find some detail of classification or emphasis with which he disagrees; and the presentation tends occasionally to degenerate into a list of observations and opinions with little criticism of the soundness of methods or the adequacy of grounds for opinion. But the references are there and the reader can look up the originals and draw his own conclusions.

The book ends with a chapter on laboratory methods. Two criticisms may be made. Serological methods are being applied more and more to matters outside immunity; more warning might have been given about difficulties and fallacies. Serology is not all plain sailing; it may be difficult to get antibodies against a particular antigen, and any antibody one gets may be against an impurity. Boyd might have quoted, as an example, the experiences of Cohn and colleagues and of Borduas and Grabar with ovalbumin and conalbumin. Also more might have been said about the newer techniques that are becoming popular; for example, the red-cell sensitization technique, which is merely mentioned, and the tanned-cell method, which is not mentioned at all. One can find the technique of the Wassermann reaction in many books, but not these and the Ouchterlony and Oudin methods.

Although this book will prove indispensable for research workers and advanced students, it would not help medical students and practitioners; there is too much controversial detail.

A better book for non-specialists is Carpenter's "Immunology and Serology". The author gives a clear and balanced account of modern knowledge and theories of serology. He admits that he has placed greater emphasis on serology, "partly because more is known about it". In fact, "Infection and Immunity" and "Antiviral Immunity" together get only twenty-nine pages out of the total 351; both "Allergy" and "Experiments in Serology" get as many pages. Although these twenty-nine pages give most of what is known about the defences of the individual (as opposed to external influences which should be classed under hygiene), more might have been written about the values of immunization against typhoid and pneumonia (both of which Boyd mentions) and against whooping cough, and about the role of antibodies in protection against these diseases. Discussions of protection by Salk vaccine and by diphtheria toxoid are included.

J. R. Marrack

Advances in Geophysics

Edited by H. E. Landsberg. Vol. 3. Pp. x+378. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1956.) 8.80 dollars.

THE term geophysics has become synonymous with the study of all physical aspects of the Earth. There is no better indication of this than in this series of "Advances in Geophysics" with its wide range of subjects. The third volume includes a preliminary account by A. P. Crary on Arctic ice-island research, in particular Fletcher's Ice Island (*T3*), occupied during 1952–54. Byerly contributes an excellent article on crustal structure based on seismic evidence, reviewing all work from 1900 to the present day. His discussion of the peculiarities of travel-time curves is warmly recommended to all seismologists. A third article, contributed by Bullard, Maxwell and Revelle, summarizes the progress of heat-flow measurements through the oceans' floors. One cannot avoid a sense of wonder that it is possible to measure heat-flows as small as 0·5 microcalorie per square centimetre per second at such remote places. The thermal properties of the Earth are treated on a broader basis by Jacobs in an article on the interior of the Earth. Well-logging methods, in so far as they assist in the search for ground-water, are treated in outline by Jones and Skibitzke. This article, the first of its kind in book form on the application of geophysics to hydrology, discusses the self-potential, resistivity and radioactivity logging instruments and the important part they play in ground-water investigations in the United States. There is a contribution by Sekera on the polarization of light in the atmosphere and, of current interest, an account by Singer of the experimental possibilities of artificial Earth satellites. Each author has supplied an ample bibliography with his contribution and at the conclusion of the article presents a list of the symbols used together with their explanation—a debatable practice. A number of typographical and grammatical errors occur in the text. S. H. Hall

Supplement to Mellor's Comprehensive Treatise on Inorganic and Theoretical Chemistry

Prepared under the direction of an Editorial Board. Supplement 2, Part 1: F, Cl, Br, I, At, including the Radiochemistry and Radiation Chemistry of the Halogens. Pp. lii+1153. (London and New York: Longmans, Green and Co., Ltd., 1956.) 170s. net.

THE first edition of the handbook of chemistry by Leopold Gmelin appeared in 1817, and the latest edition is at present in course of publication. Whether its English counterpart, the treatise of Mellor, will have such a long life, only the future can show. In most editions of Gmelin, a new one was begun before the preceding one was completed, but the editors of Mellor have adopted what is probably a better plan, of issuing supplementary volumes to bring the whole work up to date. The first of these has now been published. Although on the same plan as the original, it has some better features. Instead of the solid blocks of literature references, without any apparent organization, the present volume has numbered references to fairly short sequences, the page references to which are given at the foot of each page of the text. This makes the book very easy to use. The text is obviously based on a careful study of original sources and is more critical than Mellor's, although this has not been overdone; 'obsolete' material has a habit of coming to life again in inorganic chemistry. Numerical data, curves, and diagrams of structures are freely given, and the descriptions of experimental methods are adequate. It can safely be said that if later volumes are as good as this one, the book will be worthy of Mellor's work. The volume is quite indispensable in all chemical libraries. J. R. Partington

Solvents

By Dr. Thomas H. Durrans. Seventh edition, revised. (Volume 4 of a Series of Monographs on Applied Chemistry.) Pp. xv+244. (London: Chapman and Hall, Ltd., 1957.) 30s. net.

THIS is the well-known monograph to which one instinctively turns when seeking information on solvents. First published in 1930, it has now reached its seventh edition, which is sufficient indication of its usefulness and of the determination of its author and publishers to keep it up to date. The present edition retains the same general structure as its forerunners. The first part discusses the more theoretical aspects of the subject with chapters on solvent action, solvent power, plasticizing solvents, solvent balance, viscosity, vapour pressure, inflammability and toxicity; while the nine chapters in the second part deal in detail with the characteristics and uses of the individual solvents and plasticizers. Very useful appendixes give a comprehensive list of trade names with probable compositions, solubility tables and plasticizer proportions. The list of trade names now runs to more than six hundred entries and the solubility tables give information on the solubility of twenty-seven different substances such as cellulose acetate, rubber, gums and oils in more than a hundred different solvents. The volume is of convenient size and well produced. E. H. Nurse

Extraction and Refining of the Rarer Metals

Proceedings of a Symposium on Extraction Metallurgy of some of the Less Common Metals arranged by the Institution of Mining and Metallurgy, held on 22nd and 23rd March 1956, at the Royal Society of Arts, London. Pp. xviii+444+14 plates. (London: Institution of Mining and Metallurgy, 1957.) 60s.; 8.50 dollars.

THE subject-matter of this Symposium is one in which considerable developments are occurring, but known only to a limited number. The Institution of Mining and Metallurgy is, therefore, to be congratulated on presenting these papers and discussion to a wider audience. The papers deal with eleven of the less common metals, but uranium, vanadium, niobium and beryllium are the ones receiving most attention. Broadly, two kinds of information are to be obtained from the proceedings. On one hand, as is to be expected, there are details of processes for specific metals; on the other, there is considerable information in more general terms on the principles of various techniques, including a number of new methods, such as ion-exchange and solvent extraction for the claiming of values from leach liquors. Although the theme is predominantly chemical, there is some reference to the physical processes of ore-dressing. Apart from this specific technical matter there is revealed in a general way the considerable stimulus and development in extractive metallurgy brought about by the need for some of the newer metals and principally uranium. Moreover, it is edifying to see the position which has already been reached. A. R. Bailey

THE ROYAL SOCIETY OF CANADA

SEVENTY-FIFTH ANNIVERSARY MEETING

AT its annual meeting, held at the University of Ottawa in June, the Royal Society of Canada celebrated the seventy-fifth anniversary of its foundation. For this occasion a symposium entitled "Our Debt to the Future" ("Présence de Demain") had been organized.

The Society was founded on the initiative of the Governor-General, the Marquess of Lorne, in 1882 for "the promotion of Literature and Science within the Dominion". It is now organized in five sections: (I) Humanités et sciences sociales; (II) Humanities and Social Sciences; (III) Mathematical, Chemical and Physical Sciences; (IV) Geological and Allied Sciences; (V) Biological Sciences; and in so far as barriers between the sections can be crossed with ease, the Royal Society of Canada can contribute to the cultural life of the country by bringing together persons who have achieved distinction in these various branches of learning. It is not, like the Royal Society of London, exclusively devoted to science, and it is required to bring together men speaking two different languages with differing cultural sensibilities.

In the past few years there has evolved a new appreciation of the Marquess of Lorne's idea of the service the Society should render to Canada. It is recognized that the separate sections of the Society can no longer play the parts that are now much more effectively filled by the many associations of specialists such as the Canadian Historical Association or the Canadian Association of Physicists. The Fellows of the Society have to learn to devise new forms of intellectual intercourse to restore cultural unity in the midst of diversity of special interests, and to respond to the need of this rapidly developing country for inspiring intellectual leadership. The time for this change is appropriate, for it accompanies the institution of the Canada Council by the Parliament of Canada.

The symposium was held on the afternoons of June 10, 11 and 12 in six sessions. It was opened by Prof. D. L. Thomson (McGill), speaking on "The Roles of the Scientist and Scholar in Canada's Future" (Le rôle de l'homme de science et de l'homme de lettres à l'egard de l'avenir du Canada), Principal W. A. Mackintosh (Queen's), president of the Society, being in the chair. Replete with pointed allusion to the Canadian scene, this address laid most emphasis on the educational processes and institutions by which scholarly and scientific influence can be brought to bear in Canadian life, and commented on current standards of values, with hope for the future of Canadian universities.

The second session, "The Penalties of Ignorance of Man's Biological Dependence" (Nos Servitudes Biologiques) was presided over by Prof. E. G. D. Murray, who recently retired from the chair of bacteriology and immunology at McGill University and will edit the book to be published for the Society by the University of Toronto Press based on the symposium. K. W. Neatby (director of Science Service, Ottawa) led off on the theme "We are not masters of our own destiny because many essential contributors to our existence, or to our destruction, are independent of man, and because of the inadequacy of our knowledge of the genetics and physiology of individual species and the complexities of biological interdependence". Prof. I. McT. Cowan (University of British Columbia) transferred the discussion from plants to animals. The problem salmon versus power on the Fraser River, B.C., evoked comment from the floor that the advent of nuclear power should save the Fraser for the salmon. Dr. G. H. Ettinger (Queen's) discussed man's internal environment, and the lone chemist participating, Dr. R. H. F. Manske (Dominion Rubber Company) concluded by suggesting that the organic chemist can probably play a larger part in coping with the biological problems than the biologists seem to think. These papers were somewhat too condensed for the general audience. The chairman summed up by saying that scientists should be less timid: they should demand and be granted more influence in the use of their knowledge, more say in the determination of financial needs for scientific research and some influence to oppose political expediency in matters affecting man's environment.

On the following afternoon Dr. N. A. M. MacKenzie (University of British Columbia) presided over the session on "The Social Impact of Modern Technology" (Conséquences sociales des progrès techniques). The sudden illness of Prof. J.-C. Falardeau (Laval University) prevented his presenting the social scientists' point of view. The session was opened by Prof. V. W. Bladen (Toronto), speaking as economist and humanist on the broad aspects of social adaptation to technological change. Dr. E. W. R. Steacie (National Research Council) emphasized that technological developments come to fruition because society wants them. Instead of laying at the door of science blame for the technical ills that afflict us, we should examine the activities of the advertising fraternity who, he had been led to believe, are products of liberal arts education. Prof. W. H. Watson (Toronto) asserted that to succeed, modern technology has to be good science, and using men for functions that cannot be performed economically by machines demands better, more responsible attitudes to work. He challenged thinkers in the universities to examine whether intellectual stimulus to-day does not lie in the field of the technologists.

The fourth session, "Our Economic Potential in the Light of Science" (Les découvertes scientifiques et l'expansion économique), presided over by Prof. H. C. Gunning (University of British Columbia), brought together a geologist, a metallurgist and two economists. Prof. J. E. Hawley (Queen's) presented our dilemma in relation to the mineral resources of Canada: although we have a debt to future generations of Canadians, we have at present one to the free world in need of raw materials. Should we attempt to conserve some or all of those we have, or alternatively can we hope to replace those we use by new discoveries? He suggested that it would be helpful to commit to a national advisory board continuing consideration of these matters. Prof. L. M. Pidgeon (Toronto) forecast the depletion of accessible deposits of rare metals and the trend towards increased use of those metals that constitute a major portion of the Earth's crust—aluminium, magnesium, iron and titanium. With the exception of iron, they are reactive metals requiring large amounts of energy to produce. This 'high-level' energy is supplied at present from water-power. The trend to remote hydro-electric locations will continue until available sites are saturated. Thereafter nuclear energy may level the cost of electrical energy throughout industrial nations. The economic consideration of mineral resources was taken up by Prof. B. S. Keirstead (Toronto) and M. Lamontagne (Ottawa) and led to some naive questions by scientists about the technical meaning of 'capital'.

On the afternoon of June 12, the session on "Human Values and the Evolution of Society" (Les valeurs humaines et l'évolution sociale) was introduced by Father Levesque, who presided. The session was intended to bring biology and humanism together, and to this end Prof. T. W. M. Cameron (McGill) spoke about man from 'a worm's eye' view. Prof. A. S. P. Woodhouse (Toronto) made a memorable statement: "Civilization requires to be defined in terms of the good life". Education must extend its influence "from intellectual training which is its centre, to a refinement of sensibility—to the cultivation of understanding, imagination, sympathy and tolerance and to the fostering of talent and of the kind of individuality that operates harmlessly and beneficially within the framework of a free society". But he was surpassed in creating the transcendental occasion by two poets, the first, Robert Elie (Montreal), speaking in French, and the second, Roy Daniells (University of British Columbia), in English.

The closing session, "Let us Look to our Human Resources" (Recours aux forces spirituelles), was presided over by F. H. Underhill, curator of Laurier House, and opened by Dr. J. K. W. Ferguson (director, Connaught Laboratories). Trends in life expectancy in Canada and elsewhere in the world will affect us by menacing pressures of population and by modifying attitudes and aims in life. Prof. L.-P. Dugal (Ottawa) discussed the need for change in educational patterns in Canada. G. V. Ferguson (editor of the *Montreal Star*) spoke of the influence of mass media, and Dr. W. B. Lewis (Atomic Energy of Canada, Chalk River) of the efficient use of man-power with more than passing reference to the universities.

The symposium, which was open to the public, was well attended.

In the evening following the symposium, at a dinner attended by the French Ambassador and the High Commissioner for the United Kingdom, who presented messages from the French Academy and the Royal Society of London, respectively, the Society was addressed by the Governor-General, Mr. Vincent Massey. His announcement that Prince Philip had accepted the invitation to honorary fellowship in the Society was warmly received.

W. H. WATSON

THE ELECTRICAL RESEARCH ASSOCIATION

NEW LABORATORIES AT LEATHERHEAD

ON June 26, Lord Mills, Minister of Power, opened the Electrical Research Association's new Laboratories at Cleeve Road, Leatherhead. In his address, Lord Mills, who was welcomed by Sir Gordon Radley, president of the Association, stressed his life-long belief in the importance to Britain of industrial research. In his fifty years of participation in industry, he said, he had witnessed the peak of Britain's industrial supremacy based on the exploitation of the steam engine and had seen that supremacy challenged by other countries. These countries had tried, by intensive education and application, to overtake Britain's lead in discovery and inventiveness. Now it seemed to him that a second revolution was upon us, the age of electricity, which was changing our habits of life and our knowledge of world affairs as much as it was altering our material standards. Here then, he felt, was another opportunity which, combined with the dazzling prospects of nuclear power, should excite the imagination of young people and attract them to research and development in the electrical field. Lord Mills unlocked the doors of the main building with a gold key and the laboratories were thrown open for inspection, the principal guests being taken on a conducted tour. Altogether, about five hundred visitors and guests were present, and a similar number attended on the following day.

The site at Leatherhead, which covers about 40 acres, was acquired in 1943 when it became evident that the 1¾ acres containing the Perivale laboratories would be unable to meet the post-war needs of the Association. At that time many of the non-technical and administrative staff occupied part of the building of the Institution of Electrical Engineers in London, for which it was known that the lease would not be renewed when it expired in 1947. A scheme was prepared by the architect, Mr. H. J. Rowse, in 1946, which envisaged centralizing practically all the activities of the Association on the new site, at an estimated cost of £1 million. For certain reasons, the Council deferred implementing this plan and proposed a first stage costing £600,000, which would leave the high-power studies at Perivale and transfer the administrative staff to premises which had been acquired at Thorncroft Manor, Leatherhead. In 1950 this target was further reduced to £400,000, so that the buildings which were, in fact, erected in 1955–56 cost about £328,000 at 1946 price levels, or about one-third of the original scheme.

There are now three buildings on the Cleeve Road site, a main building (Fig. 1), a high-voltage building and a workshop. The main building contains essentially general-purpose laboratories rehousing the work and equipment which have been transferred from Perivale, where it had reached an acute state of over-crowding. It also houses a library and has a total floor area of some 48,000 sq. ft. There are three main floors, which extend through a central section

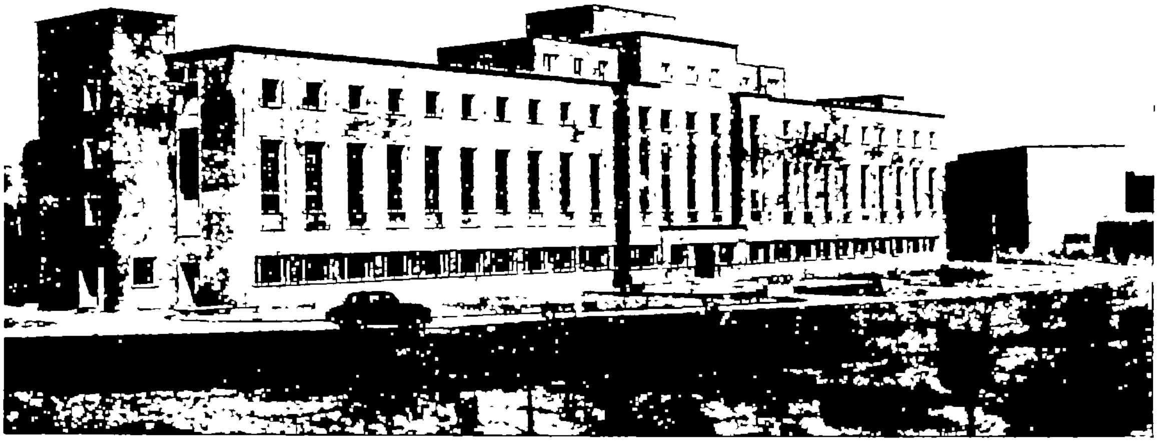

Fig. 1. Cleeve Road Laboratory, main building

and two wings north and south on the same elevation. The ground floor and the second and third floors are of normal height, while the first floor is 18 ft. high with the mezzanine floor running the whole length of the building and covering about one-third of the area. A third west wing at right angles from the central section has three floors of normal height. Altogether there are fifteen laboratories, each with a standard floor space of 50 ft. × 35 ft.

Practically all the current work in this building was shown in its natural habitat. Altogether, nearly one hundred exhibits were to be seen, varying from single pieces of special apparatus to major investigations involving considerable amounts of equipment. In the south wing of the ground floor were to be found a series of investigations concerned with the continuous and short-circuit rating of cables and the movement of moisture under thermal gradients in the soil surrounding cables. In the north wing experiments on transformers and the analysis of lightning fault statistics are carried out. Experiments on the cooling of both transformers and the buildings containing them, as well as the studies of magnetic properties of windings and core, were exhibited. The west wing of the ground floor is devoted to problems of space heating and contains a special room the surroundings of which will be under temperature, humidity and wind-speed control. Other interesting work here includes latent heat thermal storage and domestic heat pumps. The whole of the buildings at Cleeve Road are indeed being operated under close control as a space-heating study. Off-peak storage was adopted in preference to heat pumps because of difficulties and uncertainty in securing a low-temperature source. Three forms of off-peak storage are used according to circumstances. The main building uses hot water storage with circulation through a conventional radiator system; the high-voltage laboratory, where the staff and most of the equipment are to be found in the lower part of a high building, employs floor heating. Floor heating is also used in the workshops, whereas in the canteen, which is used only for short periods, block thermal storage is being tried.

A network analyser is under construction in the south wing of the first floor. Part of this is already in operation and has been used for the solution of appropriate problems, including transient stability of power systems and heat flow problems in two dimensions. The north wing of the first floor is concerned with the electric strength of solid insulation and covers some of the fundamental work on dielectrics, such as intrinsic versus electromechanical breakdown and the microscopic study of breakdown channels as well as problems of tracking and life tests in the presence of discharges. Certain service problems concerned with the vibration of overhead lines and prototype development of instruments for the non-destructive testing of insulation are also situated on this floor.

The first floor of the west wing houses those parts of the fundamental work on the electric arc which can be carried out with low power.

Ascending to the second floor, it was possible to gain some appreciation of the detailed knowledge that the Electrical Research Association has accumulated on radio interference, its measurement and control. The safety of electrical equipment in explosive atmospheres and its converse, the ignition of explosive mixtures in automotive systems, have been studied side by side for a good many years. On the same floor there is a considerable section devoted to the physics and chemistry of materials, particularly insulating materials. Quite a lot of this work is of an *ad hoc* nature, and finds one of its more basic counterparts in crystal physics in the west wing.

The high-voltage building, which is some 200 yd. from the main building in order to reduce interference, marks a considerable advance on the facilities and equipment which were available before. The surge hall has a floor area of 100 ft. × 50 ft. and is 50 ft. high. This houses a 2·8 million volt surge generator (Fig. 2) and two smaller generators of 1·3 million and 200,000 volts, respectively. It will

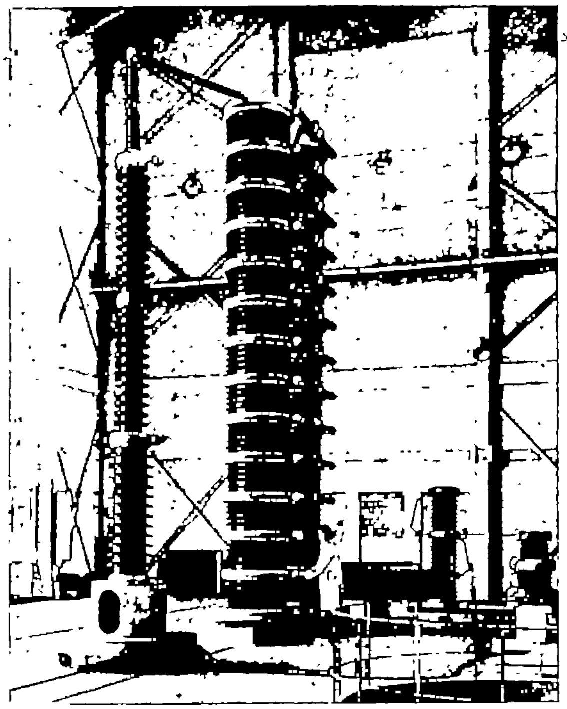

Fig. 2. 2 8 million volt surge generator

also be equipped with a 50 c./s. test transformer set of 1 million volts, a high-current surge generator and high-voltage d.c. equipment. It will thus be possible to apply all the tests required for equipment used in service at the highest supply voltages at present used or contemplated. The main hall is flanked by wings of normal height containing a transformer laboratory, generator room, instruments room, dark room and offices.

The workshop is a single-story building with a floor area of 16,000 sq. ft. It contains ample room for expansion, and at present part of it is occupied by a canteen which serves the staffs both from Cleeve Road and Thorncroft Manor.

During the open days a small exhibition on the ground floor of the main building recalled some of the past achievements of the Electrical Research Association. This included the early work and inventions in switchgear and showed some of the first experimental models of the gas-blast and side-blast pot circuit breakers. Another pre-1925 research, dealing with the rating of buried cables, was estimated to have effected an appreciation of around £4 million in the value of the cables installed at that date. Another research project, on the properties of steam at high temperatures and pressures and the behaviour of metals under similar conditions, has continued for many years, and has been of key importance in raising the thermodynamic efficiency of generating stations.

Fundamental research on dielectrics, too, started early in the programmes of the Electrical Research Association and has continued to prove of the greatest value to industry, being responsible for savings of around £1 million per annum. Other subjects included were lightning discharges and protection, radio and telephone interference, space heating, the welding arc, applications of electricity to agriculture, meter jewels, fuel cells, bomb and mine locators, the war-time work on degaussing, etc. Less tangible, but none the less of great consequence, is the service to British national and international prestige which the Association has given not only by successful contributions to research but also by the work it has done on standardization and similar committees.

These new laboratories and the space available at Leatherhead greatly enhance the facilities of the Association and should provide it with the opportunity to match the expansion which took place after the move to Perivale in 1935. Besides the sections, such as switch and control gear, which have still to be moved to the new site and for which greater facilities are required, there are many new fields of research and development in the electrical industry which have held the centre of the stage since the War and which would seem fitting subjects for co-operative research. It can be hoped that some of these will soon be included in the Association's activities.

HOW GLUE STICKS

By Dr. NORMAN A. de BRUYNE

Managing Director of Aero Research, Ltd., Duxford

MICHAEL FARADAY was keenly interested in adhesion. In 1833 he wrote: "I am prepared myself to admit (and probably many others are of the same opinion), both with respect to the attraction of aggregation and of chemical affinity, that the sphere of actions of particles extends beyond those other particles with which they are immediately and evidently in union. . . . Bodies which become wetted by fluids with which they do not combine chemically, or in which they do not dissolve, are simple and well known instances of this kind of attraction. . . . Still better instances of the power I refer to . . . are furnished by the attraction existing between glass and air, so well known to barometer and thermometer makers, for here the adhesion or attraction is exerted between a solid and gases, bodies having very different physical conditions, having no power of combination with each other, and each retaining during the time of action, its physical state unchanged"[1]. Faraday said, in effect, that glue sticks because of the unsatisfied molecular forces emanating from a surface, and nothing that has happened since has caused us to believe otherwise.

The reality of these interfacial forces can be shown in many ways, of which perhaps the most fundamental is the rise in temperature that occurs when a solid is immersed in a liquid[2]. The effect is usually small but can be easily demonstrated by using aluminium oxide powder specially prepared for chromatographic analysis to have a large surface area. When about 30 gm. of aluminium oxide are added to about the same amount of water a rise in

---

[*] The substance of a Friday Evening Discourse delivered at the Royal Institution on May 31.

temperature of as much as one or two degrees C. can be observed.

Prof. D. D. Eley has found that the heat produced when aluminium is immersed in water is $2 \cdot 7 \times 10^{-5}$ cal./cm.^{2}, or in more convenient units, 1,134 ergs/cm.^{2} of metal surface. This heat results from the rush of the water molecules into 'the sphere of action' of the aluminium surface atoms, and so one might expect that the energy gained by the water molecules would be 1,134 ergs for each square centimetre of aluminium. This is not quite true, however, because those water molecules 'bound' to the aluminium cannot move freely and their kinetic energy is taken up by the free water molecules. As a result, therefore, a slightly higher temperature will be observed than if all the molecules had shared equally in the gain of energy. It is only at absolute zero that the gain in energy equals the heat produced, because at absolute zero all the molecules will initially be at rest.

For our present purpose, which is to establish the order of magnitude, we may neglect this correction, and we can then easily write down how much work we must do to get those adsorbed water molecules away from the aluminium surface. It will be about (1,134 + 74) ergs/cm.^{2}. That 74 ergs/cm.^{2} is the additional work done in making a new water surface. Thus (1,134 + 74) or 1,208 ergs/cm.^{2} is the work required to break the joint between the water and the aluminium.

The force necessary to break one square centimetre of water–aluminium interface is obtained by dividing the work required by the distance over which the forces, due to the surface atoms, act. That distance will be about three angstroms, from which calculation shows that the stress needed to break the interface is equivalent to 584,000 lb./in.^{2}.

These interfacial forces are enormous. Even if the immersional heat of wetting is very small, as when a material like polytetrafluoroethylene (PTFE) is immersed in water, it must still be at least 74 ergs/cm.^{2}, which is equivalent to a breaking stress of some 36,000 lb./in.^{2}. Too much importance should not be attached to such figures, as Dr. Tabor has pointed out[3]; nevertheless, they indicate that the forces of adhesion need be no weaker than those of cohesion. How is it that glued joints are, in fact, so much weaker than these calculated values? This question and the possible answers to it form the substance of this article.

The problem is not so much how glue sticks, as how it is that a glue does not stick as well as it should; and how it is that a given glue will stick well to some solids and not to others; and why, if the surface forces are so strong, any glue is needed at all. Consider the last question first.

If two clean, dry, polished steel blocks are put together, why, if the surface forces are so strong, do they not adhere spontaneously? The answer is that, on an atomic scale, the surfaces are very rough and dirty. Even polished surfaces make contact at only a few places. This can be demonstrated with the surface of a glass prism displaying total internal reflexion. A rubber ball pressed to the reflecting surface shows itself as a greyish circular patch; but one of the polished steel gauge blocks pressed to the surface cannot be seen at all. The steel is in molecular contact with the glass at only a very few isolated points of molecular dimensions, whereas the rubber, which can be deformed, is in molecular contact over a somewhat greater area. The elastic energy stored up in the compressed ball is sufficient to disrupt the bonds as soon as the pressure is released. Thus, if two clean solids could be deformed plastically they would adhere, because there would then be little or no elastic energy stored up in the junctions. This can be done with soft aluminium at room temperature, as was discovered some years ago at the Research Laboratories of the General Electric Company (British Patent 644795). The surfaces are cleaned with a scratch brush, then placed quickly together and deformed locally with a punch. A good joint will result. If the cleaned surfaces are touched before the plastic deformation no adhesion takes place. That illustrates the point that surfaces must be scrupulously clean. That is a general rule in all gluing operations.

Another way in which a solid can be made to adhere spontaneously is to choose one which can be made atomically smooth. Mica can be cleaved so that it is smooth to about a few angstroms over a visible area. If we put it together again quickly it will adhere[4]. Dr. J. S. Courtney-Pratt and Dr. Anita Bailey[5] have arched up two sheets of mica, each silvered on one side, and placed the unsilvered sides in contact with their axes of curvature at right angles. By the interference fringes produced, they verified that the area of contact chosen was smooth. They found that the joint spontaneously made had a shear strength up to 14,000 lb./in.^{2}, which is as strong as the mica itself.

Because even polished metal and glass surfaces are far from smooth in an atomic sense, it is convenient to obtain contact by the use of a liquid adhesive that will run into the irregularities. This liquid is then usually, but not invariably, solidified. The effectiveness of a liquid in improving the contact between solids can be verified by pressing a wet finger on to a glass prism; the total internal reflexion will be completely destroyed.

'Pressure-Sensitive' Adhesives

Adhesives are not invariably solidified: there is a class of adhesive—the 'pressure-sensitive' adhesives—which always remain mobile. By remaining viscous, they avoid one of the causes of poor adhesion—the residual or 'locked-in' stress that is set up on solidification. On the other hand, they are never very strong, and they creep under quite a small load.

Any fluid, even air or water, can act as a 'pressure-sensitive' adhesive, as was shown in 1874 by Stefan[6], who called the effect 'apparent adhesion'. He calculated how the time of separation, t, of two disks, each of radius R, is influenced by their initial separation D, the viscosity η of the liquid in which the disks are immersed, and the normal force F applied, and obtained the equation $t = 3\pi\eta R^4/4FD^2$. The time is inversely proportional to the square of the initial separation—hence the name 'pressure-sensitive' adhesives. Stefan's measurements did not confirm this equation, but if we assume that the value of D was always greater by 15μ than his measured value, excellent agreement is obtained[7]. Stefan's analysis neglects capillarity, and is thus strictly applicable only to disks that are fully immersed in the liquid. However, if the viscosity is high, Stefan's formula can be applied to a liquid mass that fills the gap between two disks in air.

We see an example of the influence of capillarity if we first breathe on two polished steel blocks before putting them together; they will now adhere to one another. Provided a liquid wets both adherends there will be a force of attraction between them. A water film 10^{-6} cm. thick will exert an attractive force of about one ton per square inch. These considerable forces are operating when a wetted gummed label or stamp is stuck on a wettable surface, such as clean paper or glass. But capillarity will oppose adhesion if one or both surfaces cannot be wetted; just as soon as the pressure is removed the water will push the adherends away from one another. Thus a gummed label cannot be stuck on a waxed or varnished surface[8].

Because of their low viscosity and their volatility, simple liquids such as water are not suitable materials for pressure-sensitive adhesives. In practice, such adhesives are made from highly viscous materials of complex rheological properties; the difficulty of application is overcome by applying them in solution, or as a hot melt, to a tape backing so that they wet and thus adhere firmly to the backing. They never wet other materials at room temperature because of their high viscosity. The discovery that one could roll up such a coated tape and then unroll it again was an apparently trivial observation that gave birth to a new industry. The low mobility of these adhesives prevents them from getting down into surface irregularities, but they stick tenaciously because, when an attempt is made to peel the tape off, a line of high compressive stress runs just ahead of the line of tearing. This can be demonstrated on a glass prism showing total internal reflexion, or by pulling apart two tapes that have been stuck together over a small area. As the two tapes are pulled apart, this contact area continues to run ahead of the split. This is an example of the complex way in which glued joints resist external loads.

Solidifying Glues

To make a joint strong enough to satisfy an engineer a liquid adhesive must be solidified, and this can be done in various ways. A solid, previously dissolved or dispersed in a liquid, can be allowed to dry out; this is only possible if one or both adherends are porous, as are wood or paper. To make strong joints between non-porous materials such as glass and metal, we must use a glue free from solvents. One way is to freeze a molten solid (the sealing wax technique); another way is to use a liquid the molecules of which can be made to polymerize and/or cross-link with each other *in situ*.

Whatever method of solidification is used, there is almost always some shrinkage on solidification. This is undesirable because a residual stress will be 'built in' the joint. The difficulty is overcome in glass-to-metal joints by matching the thermal contraction of glass and metal and/or by encouraging plastic deformation of the metal[9]. Since the residual stress decreases as the thickness of the adhesive layer is reduced, it is desirable to use a thin glue layer. Even polyethylene is an effective adhesive for metals if it is used in a thin layer, or if its contraction is resisted by the incorporation of sufficient glass fibre.

It is important also to make sure that the adhesive, while still liquid, runs into the irregularities of the surfaces of the adherends. This requires a glue that wets the adherends and which does not solidify too quickly. Lack of contact does not merely signify lack of glued area but, far more serious, as Dr. W. C. Wake has pointed out to me[10], it can produce cracks that will be self-propagating as soon as the external load reaches a critical value which, according to Griffith's theory, will be inversely proportional to the square root of the radius of the crack.

If an adherend has 'ink bottle' pits in its surface, that is, pits the radii of which increase with depth, then it is almost impossible to get good joints because the capillary driving pressure is so small. Such 'ink bottle' pits can be produced in wood, as Dr. M. G. M. Pryor has shown (unpublished work), where the ends of the cells have been burred over; the remedy, discovered by Mr. C. A. A. Rayner[11] before the Second World War, and which was made mandatory during the War after serious aircraft accidents, is to sand the wood first. An equally important cause of failure in gluing wood is the use of an adhesive that solidifies too slowly; a starved joint will then be produced, with most of the glue in the wood instead of at the interface[12].

The tiny air bubbles trapped by the adhesive in the surface of an adherend are probably of great significance in adhesion. The stability of such air bubbles is influenced by the shape of the pit and by the angle of contact. On a wetted plane surface the liquid will 'pinch off' air bubbles but, if the bubble makes a finite angle of contact, it can grow to quite a large size before becoming unstable. It is tedious but not difficult to compute the influence of contact angle on the shape of air bubbles trapped in pits of various kinds and sizes[13], and some of the results are shown in Fig. 1. Although these bubbles may be too small to be seen, they can be 'developed' if the liquid is previously saturated with a permanent gas and then slowly warmed up. The excess pressure inside an air bubble of radius r is $2T/r$, where T is the surface tension; as a consequence, the pressure becomes high as r tends to zero, so that formation of new air bubbles tends to be suppressed, and it is much easier for an existing air bubble to grow. This indeed proved to be the case using water saturated with air or with carbon dioxide. The growth of the bubbles is best observed by making a time-lapse

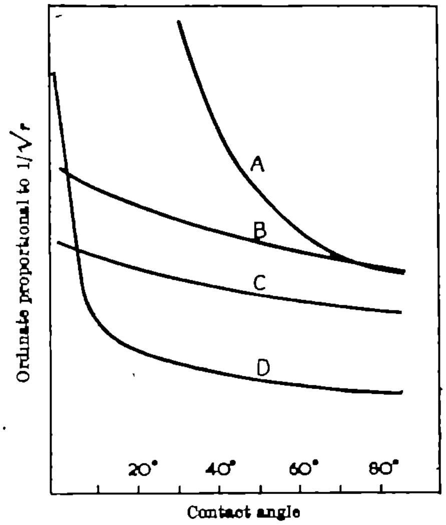

Fig. 1. Relation between contact angle and tensile stress at which progressive cracking takes place. Curve *A*, shallow spherical pit, radius 10^{-4} cm.; *B*, 45° conical pit, $r = l = 10^{-4}$ cm.; *C*, 45° conical pit, $r = l = 10^{-3}$ cm.; *D*, shallow conical pit, $r = 10^{-3}$ cm., $l = 10^{-4}$ cm. (r = radius, l = depth)

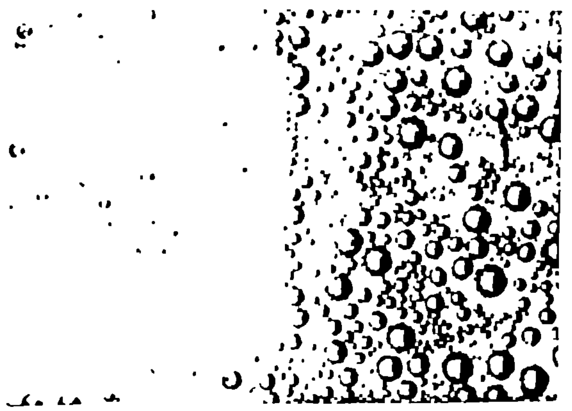

Fig. 2. Plates of polished glass (left) and polished 'Perspex' (right) lying horizontally, immersed in 'soda water'

cinematograph film. Fig. 2 is a reproduction of a single frame from such a film; it shows a polished glass plate on the left and a polished 'Perspex' plate on the right lying horizontally and immersed in 'soda water'. Letters *G* and *P* had been previously marked out on the glass and 'Perspex', respectively, in the form of little conical pits. There are a few bubbles on the glass, mostly in the *G* pits and at the edges where it had been accidentally smeared with the bitumastic paint backing. The 'Perspex', on the other hand, is covered with bubbles the diameters of which reach 3 mm.

Such moving pictures provide a vivid impression of why it is so difficult to make strong joints to hydrophobic surfaces with hydrophilic adhesives, and why cavitation is so much more pronounced on a hydrophobic than on a hydrophilic surface[14], and why polytetrafluoroethylene is both such an effective anti-bumping agent in vacuum distillation of liquids[15] and such a good material for the surfaces of skis. The only way to glue hydrophobic materials such as polytetrafluoroethylene, polyethylene[16], rubber and polystyrene with hydrophilic glues is to make their surface wettable, although some of these materials can, of course, be glued together with solvents that eventually diffuse into the adherend. If lap joints between 'Alclad' strips, 1 in. wide with 1 in. overlap, are made, with an adhesive consisting of polyethylene sheet coated on both sides with an epoxy adhesive, the results shown in Table 1 are obtained.

Table 1. Strength (lb.) of lap joints made with:

untreated polyethylene	flamed polyethylene
150	920
150	600
190	650
150	780
150	800
200	750
Mean: 165 lb.	Mean: 750 lb.

Rubber can be treated by brief immersion in concentrated sulphuric acid; polytetrafluoroethylene requires immersion in a solution of sodium in liquid ammonia.

By subjecting pieces of polyethylene sheet to increasing times of immersion in chromic acid, contact angles against water can be obtained varying from about 90° to about 40°, and the joint strengths of comparable lap joints are shown in Fig. 3 plotted against the contact angle. By comparing Fig. 3 with Fig. 1, one sees that there is a similarity between the observed joint-strength and the computed value of $1/\sqrt{r}$. This gives support to the suggestion that hydrophobic surfaces make poor joints because the air bubbles act as nuclei for crack propagation.

The stresses set up in a glued joint by an external load are usually complex. For example, neither the lap joint nor the butt joint produces a uniform stress in the glue. The way that the adherends are deformed under load is just as important as the manner in which the glue behaves. That is why a given glue will give widely differing strength figures with different materials, or with different types of joint, even though rupture occurs in the glue. A review of this aspect of adhesion is given in Chapter 4 of ref. 7.

Adhesives for Metals

The application of the principles described above, as well as the availability of plastic materials that can be cross-linked or polymerized without evolution of volatiles into strong solids, has provided the aircraft engineer with quite new possibilities of construction. In thin gauges such glued joints can be far stronger than riveted or spot-welded joints. But of greater significance is the greatly improved fatigue resistance obtainable; the fatigue strength of riveted structures is much inferior to that of comparable glued structures[17]. As a corollary, the fatigue strength of riveted joints can be greatly improved by local reinforcement with a glued-on lamination.

The use of glue gives the aircraft designer a new weapon against fatigue failure and a new freedom in design. It enables him to thicken up a structure by lamination, without the expense of machining from the solid, and without fear of the rapid crack propagation to which integral structures are subject[18]. Outstanding examples of glued structures are to be found in such machines as the de Havilland 'Comet' and the Fokker 'Friendship'.

The development of strong glues for metals has also made possible a new type of construction in which two outer skins are stabilized by a honeycomb

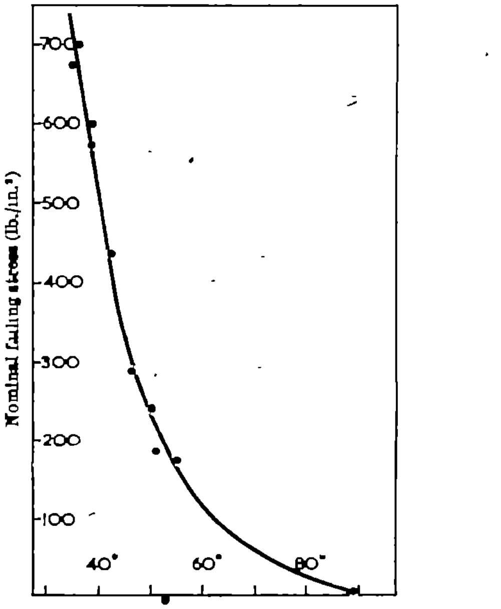

Fig. 3. Variation of tensile shear strength of 'Araldite'–polyethylene joints with contact angle (of water against polyethylene)

core of metal. This construction is of great value wherever the loads on a structure are small in relation to the required size, as in a fuselage, in the control surfaces and in the outer portions of the wing of an aeroplane. The advantages of this type of structure are a considerable gain in the ratio of strength to weight, and the complete stabilization of the skins right up to the point of collapse. A fuller account of adhesives in aircraft construction has been given elsewhere[19].

I am greatly indebted to my colleagues at Aero Research, Ltd., as well as to Dr. J. S. Courtney-Pratt, for their assistance in preparing this article. Mr. Doble, Mr. R. D. Marsh and Dr. J. T. Martin in particular helped in devising the lecture demonstrations, and Mr. G. S. Neumann assisted me both in the lecture and by his systematic preparatory work.

OBITUARY

Dr. L. H. Lampitt

In the death of Leslie Herbert Lampitt on June 3 applied science has lost an enthusiastic and inspiring personality.

He was born in Warwickshire on September 30, 1887, and in 1908 graduated at the University of Birmingham with double first-class honours, in chemistry and biochemistry. In 1911 he became chief chemist of La Meunerie Bruxelloise, a post which he held until the outbreak of the First World War. He served with the Army in France throughout the War.

In 1919 Dr. Lampitt began what was to be his life's work, namely, the direction of the laboratories of J. Lyons and Co., Ltd. To understand the part that science could play in a great food firm required vision in those days, and the present fine laboratories and service—rapidly developed from humble beginnings under his guidance—are a tribute to the creative genius and foresight of their founder. He became a director of the firm in 1936.

Dr. Lampitt was keenly interested in new scientific and technological developments and would travel any distance to investigate new processes or to discuss mutual problems with scientists abroad. It is not surprising, therefore, that he became an international figure in the world of chemistry. He was particularly active in the International Union of Pure and Applied Chemistry, of which he had been honorary treasurer since 1945, and in the past decade he served on a number of Unesco and other international committees. He was also chairman of the organizing committees of several international scientific congresses, including that of surface activity held in London in the spring of this year. During recent years the international aspects of chemical documentation also claimed his attention.

In Great Britain, Dr. Lampitt had been honorary secretary of the British National Committee for Chemistry, chairman of the Chemical Council, chairman of the Bureau of Abstracts, and had held office in many of the scientific societies of which he was a member.

His greatest activity was in the Society of Chemical Industry, of which he was a past-president. At the time of his death, he had been honorary foreign secretary of that Society for a number of years. In 1932 he stimulated the formation of the Food Group of the Society and became its first chairman, and in 1951 he became first chairman of the Society's Overseas Section, which was also formed as a result of his enthusiasm. He was awarded the Society's Medal in 1943 and was the first recipient of the Society's International Medal in 1950. He received the Royal Society of Arts Silver Medal in 1947 and the Lavoisier Medal of the Société de Chimie Industrielle in 1950. He had held a number of lectureships and had published numerous papers on chemical and biochemical subjects.

Dr. Lampitt was a freeman of the City of London and a liveryman of the Worshipful Society of Apothecaries of London and of the Worshipful Company of Horners.

Although Dr. Lampitt was always at heart a scientist, he had a number of other interests. Hand in hand with his science went his religion. During his Brussels days he was a licensed lay reader and held office in the English Section of the Y.M.C.A.; at the time of his death he had been vicar's warden at the Church of St. Mary-on-the-Hill, Harrow, for many years.

In his younger days Dr. Lampitt was a keen sportsman, playing for his University in the football and cricket first elevens. He never lost his interest in drama, both amateur and professional, and was a devoted gardener. He took great pleasure in hospitality and was a delightful host.

Dr. Lampitt will be remembered by his friends all over the world for his humanity and good fellowship and essential kindliness, no less than for his scientific achievements. He is survived by his wife and his son.

E. B. Hughes

NEWS and VIEWS

Horticultural Chemistry at Bristol: Prof. T. Wallace, C.B.E., F.R.S.

At the members' meeting at the Long Ashton Research Station on July 17, the chairman, Capt. D. M. Wills, announced the impending retirement of the director, Prof. Thomas Wallace, after thirty-eight years service. Appointed agricultural chemist in 1919, Prof. Wallace became deputy director in 1923 and, in 1943, was made director of the Station and professor of horticultural chemistry in the University of Bristol. The best known of Prof. Wallace's many contributions to horticultural science are his studies of the effects on plant growth of deficiencies and excesses of the mineral nutrient elements. Started in his early days at Long Ashton as sand culture experiments to determine the major nutrient requirements of fruit trees and bushes, these were later to embrace all the essential elements for both agricultural and horticultural crops. His contributions in this field are epitomized in "Diagnosis of Mineral Deficiencies in Plants by Visual Symptoms: a Colour Atlas and Guide", first published in 1943 and issued in an enlarged second edition in 1951. Prof. Wallace's position as an authority on trace-element nutrition of plants was recognized by the establishment, under his direction, of the Agricultural Research Council's Unit of Plant Nutrition (Micro-Nutrients) at Long Ashton.

Most of his research work has been concerned with problems of immediate importance to growers, and his close links with the agricultural and horticultural industries have ensured the rapid translation of his findings into practice. The acceptance of his recommendations for overcoming marginal leaf scorch by potash manuring brought into production large areas of the west Midlands previously regarded as unsuitable for fruit-growing. Among other studies with practical application were those on lime-induced chlorosis, on the classification of fruit soils, and on the effects of manurial and cultural treatments on fruit quality. Under Prof. Wallace's directorship the staff at Long Ashton has been increased threefold, while the buildings and facilities have been constantly extended. His combination of administrative capability with knowledge of horticulture has led to heavy demands for his services on committees of the Ministry of Agriculture and the Agricultural Research Council, particularly during the post-war reorganization of the research and advisory services and in the establishment of the National Agricultural Advisory Service's experimental horticulture stations. These qualities were further recognized by his appointment in 1953 to membership of the Agricultural Improvement Council.

History and Philosophy of Science at University College, London: Prof. Douglas McKie

Dr. Douglas McKie, who has just been appointed to the chair of the history and philosophy of science at University College, London, of which he is a Fellow, has been associated with that College throughout his academic life. After a distinguished career as a student of chemistry, culminating in the award of the Ramsay Medal, he was attached to the Department, of which he now becomes the head, soon after its inception under the name of "History, Principles and Methods of Science" in 1924. From that time until the outbreak of the Second World War in 1939 he was the only full-time member of the staff of the Department, the head of which was the late Prof. A. Wolf, who also occupied a part-time chair at the London School of Economics. McKie was thus intimately involved in the successive experimental stages through which the Department passed in its pioneer effort to establish a new and important subject as a regular university discipline. During the War, when the work of the Department was necessarily almost entirely suspended, he assisted in the teaching of chemistry, and on its resuscitation with a greatly increased staff in 1945, he became a reader and took a prominent part in reaping the fruits of his earlier labours. He now assumes the control of a stable and successful Department with the support of a unique experience. McKie's contributions to knowledge have been concerned chiefly with the history of chemistry and the early history of the Royal Society. He has given special attention to the work of Lavoisier, on whom he has written a standard treatise; and he is taking an active part in the publication of Lavoisier's correspondence and the identification and preservation of his apparatus.

The Royal Society of Canada

The seventy-fifth anniversary meeting of the Royal Society of Canada was held in Ottawa during June 10–12. A symposium on "Our Debt to the Future" occupied each afternoon, and the final address was given by His Excellency the Governor-General at dinner on the evening of June 12 (see p. 259 of this issue). Sections of the Society held meetings in the morning only. Section III (Mathematical, Chemical and Physical Sciences) held a symposium on "Symmetry", introduced by its president (Prof. H. S. M. Coxeter), who discussed crystal symmetry and its generalizations. Section IV (Geological Sciences) met under the presidency of Prof. H. C. Gunning and held a symposium on "Hydrology". Section V (Biological Sciences) was addressed by its president, W. H. Cook, on "Research in the Biosciences: a Mid-Century Perspective", and by Prof. T. W. M. Cameron on "Parasitology and the Arctic"; a posthumous paper by Prof. G. Lyman Duff on the "Etiology and Pathogenesis of Arteriosclerosis" was also presented.

Officers of the Society for the year 1957–58 were elected as follows: *President*, Prof. T. W. M. Cameron; *Vice-President*, Pierre Daviault; *Hon. Secretary*, C. P. Stacey; *Hon. Associate Secretary*, Guy Sylvestre; *Hon. Treasurer*, N. E. Gibbons; *Hon. Editor*, G. W. Brown; *Hon. Librarian*, W. K. Lamb. Officers of the scientific sections are as follows. Section III: *President*, Leo Marion; *Vice-President*, Prof. G. M. Shrum; *Secretary*, Prof. A. D. Misener. Section IV: *President*, H. C. Rickaby; *Vice-President*, L. S. Russell; *Secretary*, S. C. Robinson. Section V: *President*, Prof. W. R. Campbell; *Vice-President*, N. H. Grace; *Secretary*, J. Gibbard.

Council for Overseas Colleges of Arts, Science and Technology

As announced in an answer on August 1 to a question in the House of Commons, the Council for Overseas Colleges of Arts, Science and Technology has been formed to replace the existing Advisory Committee on Colonial Colleges of Arts, Science and Technology. The Advisory Committee was set up in 1949, and has since then fostered the development of the Royal Technical College of East Africa in Nairobi—which was officially opened by Princess Margaret last October—of the Nigerian College of Arts, Science and Technology with branches in the three regions of Nigeria, and of Kumasi College of Technology, in Ghana. It has also assisted with the development of Fourah Bay College in Sierra Leone, and with the setting-up of the Singapore Polytechnic. The Committee is advising on the establishment of technical colleges in the West Indies. As Advisory Committee on grants for higher technical education under the Colonial Development and Welfare Acts, it has always worked in close contact with the Colonial Office.

The chairman of the new Council is Sir David Lindsay Keir, master of Balliol College, Oxford, who was chairman of the Advisory Committee. Its other sixteen members, who were also members of the Advisory Committee, include prominent educationists with wide experience of education in the overseas territories and leading figures in the field of technical education in the United Kingdom; provision has also been made for three co-opted members to be added to the Council. Payment for the Council's secretariat and overhead expenses is made largely from Colonial Development and Welfare funds. The main function of the Council is to advise the Secretaries of State for Commonwealth Relations and for the Colonies, overseas governments, governing councils of overseas colleges and other interested organizations on the development of colleges of arts, science and technology. These are defined as colleges which offer courses of general, scientific and technical education leading to professional or near-professional qualifications (not, normally, university degrees) and which encourage research—including colleges which offer, in addition, courses of a lower standard. It will be ready to assist in the recruitment of staff, and to advise on matters of academic policy. It will also seek to stimulate the interest of technical and other institutions in the United Kingdom in the overseas colleges, and to assist examining bodies and professional institutions in Britain on courses, examinations and qualifications specially designed to meet the needs of overseas students. To avoid duplication of effort, the Council will maintain close liaison with the Inter-University Council for Higher Education Overseas and with the Colonial University Grants Advisory Committee. It will also maintain close liaison with the Advisory Committee on Education in the Colonies, with the object of relating the work of the Colleges to that of other educational institutions, particularly those giving trade and technical training.

The Journal of Solar Energy Science and Engineering

PUBLICATION of a new journal intended to cater for the growing interest in practical developments of the utilization of solar energy (*Journal of Solar Energy Science and Engineering*. Pp. 64. Subscription rate: 10 dollars per year. Phoenix, Arizona: Association for Applied Energy, 1957) commenced in January as one consequence of the First World Symposium on Applied Solar Energy held in Arizona, 1955. The first issue contains articles describing a wide range of solar energy applications. Variation of solar radiation and an analysis of the effects of season and orientation of the Sun; latitude, altitude and cloudiness at the place of reception are the subjects of two papers of importance in assessing the potential value of heat collectors. A contribution from Russian scientists describes experiments in the U.S.S.R., and the projected design of a solar boiler of steaming capacity about 12 tons per hour. Other papers are concerned with photosynthesis, the design of solar furnaces and the production of cold by solar radiation. A review of world research activities on solar energy and abstracts from the literature forms a useful guide to present developments.

Volume 1, Nos. 2 and 3, published in July 1957, have been combined as the Proceedings of the 1957 Symposium at Phoenix on Solar Furnaces. A collection of twenty papers describes various applications, the principles of design and methods of control, industrial and economic factors in their use. The present largest mirror, 35 ft. in diameter, is at Mont-louis in the Pyrenees, under the direction of M. Felix Trombe, but mirrors up to 100 ft. in diameter are being designed by the Stanford Research Institute. These solar furnaces are used mainly for research on the properties of materials at temperatures up to 3,000° C., and in some cases are linked with research on high-velocity rockets and nuclear developments. This valuable survey indicates that solar furnaces have many research applications in localities where solar radiation is intense, but the development of these for routine manufacturing processes is still a matter for the future.

Tower for Optical Testing

THE manufacture of telescope mirrors requires extensive optical testing of the reflecting surfaces. In the past this has been performed in a horizontal tunnel with the mirror standing on edge. This method proved satisfactory for mirrors of moderate size, but for very large mirrors a still better technique was desired. The use of a horizontal tunnel has the disadvantage that the mirror in its cell is not supported in the same manner as it would be in the completed telescope. To overcome this difficulty, Sir Howard Grubb, Parsons and Co., Ltd., of Walker-gate, Newcastle upon Tyne, have constructed a tower, 100 ft. high, for the optical testing of large mirrors. The mirror under test is supported horizontally at the bottom of the tower. A number of floors at various heights inside the tower provide access to the optical axis of the mirror; each floor has a central hole through which the light beam may pass. Special precautions are being taken to ensure constant temperature conditions inside the tower.

International Abstracts of Biological Sciences

LAST October it was announced (see *Nature*, 178, 726; 1956) that the Council of Biological and Medical Abstracts, Ltd., proposed to change the name of *British Abstracts of Medical Sciences* to *International Abstracts of Biological Sciences*. This change has now occurred, and it emphasizes two important developments in the character of the journal. The abstracts now include a wider range of subjects and they also cover the Russian literature. The inclusion of subjects not previously covered has been promoted by the appointment to the Council of representatives from the Society for Experimental Biology. A variety of other improvements have also been incorporated, and *International Abstracts of Biological Sciences* now provides a comprehensive abstracting service for the experimental and biochemical aspects of biology. The journal is published by the Pergamon Press for the Council on a non-profit-making basis. All inquiries, and offers of help in abstracting (especially from those with a knowledge of Russian), should be addressed to the Editorial Offices, *International Abstracts of Biological Sciences*, Pergamon Press, Ltd., 4–5 Fitzroy Square, London, W.1.

British Museum (Natural History)

MORE than two hundred years ago Hans Sloane bequeathed his famous collection representing all branches of natural history, as well as manuscripts, coins and antiquities, to the nation. From this collection, the Cotton Library and the Harley collection of manuscripts, grew the British Museum. Before the Museum was a century old it had grown so big that the removal of the Natural History Departments to another site was inevitable; in 1881 the British Museum (Natural History) was opened to the public. To-day the Museum has nearly four acres of gallery space in which exhibits are set out in a form which makes nonsense of the dry-as-dust aura so often attributed to museums. A short guide to the exhibition galleries has recently been published (pp. vi+30. London: British Museum (Natural History), 1957. 1*s*. 6*d*.), which not only helps the visitor to find his way around the Museum but also helps him to see how the Trustees are constantly changing the Museum's face to meet changing conditions. In the Central Hall, for example, preparations are now being made for a series of exhibits to explain evolution. In the Mineral Gallery and Balcony a special exhibition in connexion with the current antarctic expeditions and the International Geophysical Year shows examples of rocks collected by earlier antarctic expeditions; conditions of life and work in the antarctic are also illustrated.

Science in Burma

PART of the Four-Year Plan for Education in Burma is a scheme for the improvement of science teaching. This includes the formation of science clubs to stimulate out-of-school interest and the preparation of exhibitions for schools. Science advisers who run clubs in three high-schools, two in Rangoon and one in Taunggye, have recently received gifts from the Asia Foundation in the United States of radio transmitters and receivers, model telephones, model steam engines, instruments to measure humidity and astronomical charts. The gifts were received by U. Kaung, director of education in Burma. Encouragement in setting up the science clubs has been given by members of the Unesco Technical Assistance team in Burma.

Sheffield Interchange Organization

AT the recent annual general meeting of the Sheffield Interchange Organization (SINTO), which is responsible for the pooling of scientific literature in the Sheffield area, it was reported that a recent survey had revealed 4,500 files of scientific journals in the thirty-nine co-operating libraries, covering 2,500 separate titles. Members agreed to amalgamate some of the duplicated files so as to save space and binding costs. Three new research bibliographies were produced during 1956–57 by the Science and Commerce Department of the Sheffield City Libraries. These were No. 62, "The CO_2 Process"; No. 63, "The Strength of Single Metal Crystals"; and No. 64, "Ceramic Tools". Use made of the interlending facilities continues to increase, and last year members lent to each other 3,272 items. While the Science and Commerce Department continues to lend most of these publications, research and institutional libraries in Sheffield lent 886 items compared with 559 items in the previous year.

Morphology and Cytology of Linseed Autotetraploids

INDUCED autotetraploids of three strains of linseed, *Linum usitatissimum* L., have been studied by K. K. Pandey (*Lloydia*, 19, 245; 1956) to observe their comparative morphological and cytogenetical behaviour. Considerable differences in the fibre bundles of diploid and tetraploid strains were noted, the latter being commercially inferior. A conspicuous difference in reciprocal crosses of tetraploids is thought to be due to the incompatible genetical constitution of the female parent. Crosses between $2n$ and $4n$ plants showed that they were highly incompatible. This is of great economic significance as it ensures the purity of the tetraploid strains. In cytological studies about 47 per cent of the tetraploid plants were found to be aneuploids. In studies of meiosis, various irregularities were observed. Of the aneuploids, only 58-chromosome plants produced a few seeds. Among the factors considered to be jointly responsible for sterility in tetraploid linseed were meiotic abnormalities in pollen mother cells, failure of embryo-sacs (70 per cent) to attain a fully mature, 8-nucleate stage at fertilization, presumed defective anther dehiscence (about 10 per cent) which makes self-pollination difficult, failure of the apparently fertile pollen grains to germinate, and abnormalities in a large proportion of the pollen tubes, many of which burst or aborted during their way down the style.

International Lunar Society

FOR many years amateur astronomers have been interested in selenographical studies, and many astronomical societies have lunar sections. The International Lunar Society was founded in 1956 with the object of co-ordinating the work of lunar observers. Dr. H. P. Wilkins is the first president of the new Society. A journal, *Revista de la Sociedad Lunar Internacional* (International Lunar Society, Secretary, Prof. Antonio Paluzie-Borrell, Diputacion 337, Barcelona), is to be published at intervals of six months. The first issue, which appeared in March, contains five articles on various aspects of selenography. The articles in the *Revista* are in English, with summaries in French, German and Spanish.

"Regard the Earth"

SCHOOLS, and secondary school pupils in particular, will be especially indebted to Dr. R. Fraser and to the Science Club for the inexpensive but excellent and comprehensive account of the International Geophysical Year which has been published under the title "Regard the Earth" (Pp. 24. London: Science Club, 5 Great James Street, W.C.1, 1957. 2*s*. 6*d*.). The International Geophysical Year began on July 1 and will last for eighteen months. During this time scientists from some fifty-five nations will be engaged in a great co-operative enterprise to make an extensive and complex exploration of man's environment, of the Earth's atmosphere, crust and core. The work has been divided into ten main sections: meteorology, oceanography, glaciology, ionospheric physics, geomagnetism, the aurora, cosmic rays, seismology, gravity, and latitudes and longitudes. Without a trained guide it may be difficult to grasp the essential aims and the methods to be employed in the international project. As administrative secretary of the International Council of Scientific Unions, the body which is responsible for the organization of the Geophysical Year, Dr. Fraser is probably unequalled in the capacity of such a guide, and "Regard the Earth", the small, illustrated guide book which he has written, clearly explains why 1957–58 was chosen for the project and what exciting activities and results are to be expected. The booklet is an excellent introduction to the more detailed scientific account and is strongly recommended to all school libraries.

Department of Northern Affairs and National Resources: Appointments

The following appointments in the Canadian Department of Northern Affairs and National Resources are announced: Dr. I. C. M. Place, a Canadian forester who has been engaged in teaching and research at the University of Wisconsin, Madison, since 1955, to be officer-in-charge of the Petawawa Forest Experiment Station of the federal Forestry Branch; and Dr. J. S. Rowe, senior research officer at the Winnipeg office of the federal Forestry Branch, to co-ordinate all ecological studies carried out by the Branch's forest research division. He will be based at Branch headquarters in Ottawa.

British Oxygen Fellowship Awards

British Oxygen Fellowships for postgraduate research have been awarded to the following: J. W. Arnold, for research in the Department of Chemical Engineering at the Imperial College of Science and Technology, London; R. K. MacCrone, of the University of the Witwatersrand, Johannesburg, for research in the Clarendon Laboratory, Oxford; and J. B. Thompson, for research in the Department of Physics, University College, London. Renewal of fellowship for a third year has been granted to R. A. H. Pool, to continue research in the Inorganic Chemistry Laboratory, University of Oxford.

Paul Instrument Fund Committee Awards

The Paul Instrument Fund Committee has awarded the following grants: £2,075 to Dr. E. T. Hall, senior research officer at the Research Laboratory for Archæology and the History of Art, Oxford, for the construction of an apparatus with which magnetic measurements may be made of archæological material and for the development of an instrument for applying the method of neutron activation analysis to archæological problems; and £2,600 to Dr. C. N. Smyth and Mr. F. Y. Poynton, working at the Northampton Polytechnic, London, for continuation of the construction of an ultrasonic microscope for which a grant was made in December 1954.

The Paul Instrument Fund Committee, composed of representatives of the Royal Society, the Physical Society, the Institute of Physics and the Institution of Electrical Engineers, was set up in 1945 "to receive applications from British subjects who are research workers in Great Britain for grants for the design, construction and maintenance of novel, unusual or much improved types of physical instruments and apparatus for investigations in pure or applied physical science".

Announcements

Dr. Fritz A. Lippmann, who received a share of the Nobel Prize for medicine and physiology in 1953 for his work on coenzyme A, has been appointed member and professor of the Rockefeller Institute for Medical Research, New York.

Prof. W. C. Stadie, professor emeritus of research medicine in the University of Pennsylvania, has been awarded the Alvarenga Prize for 1957 by the College of Physicians of Philadelphia, for his major contributions to knowledge of carbohydrate metabolism.

The Low Temperature Group of the Physical Society and the Institution of Chemical Engineers are jointly organizing a one-day conference on "Recent Developments in Industrial Low Temperature Gas Separation", to be held on November 26 at the Royal Institution, Albemarle Street, London, W.1. Further details can be obtained from the General Secretary, Institution of Chemical Engineers, 16 Belgrave Square, London, S.W.1.

The twelfth National Conference of the British Institute of Management, with the theme "Research —a Signpost to Better Management", is to be held in Bournemouth during November 6–8. The discussion will fall under the main headings of general management, human relations, production, economics, marketing, office management and finance. Inquiries should be addressed to the Conference Office, British Institute of Management, Management House, 80 Fetter Lane, London, E.C.4.

The annual conference of the Society of Leather Trades' Chemists will be held in the large Chemistry Lecture Theatre, University of Leeds, on September 27 and 28, when K. B. Ross, director of operations in the Industrial Group of the United Kingdom Atomic Energy Authority, will deliver the Society's sixtieth anniversary lecture, on "Some Reflexions on the Atomic Energy Industry". Inquiries should be addressed to the honorary secretary of the Society, G. H. W. Humphreys, Forestal Central Laboratories, Harpenden, Herts.

The second conference on "Pulverized Fuel", organized by the Institute of Fuel, will be held at the Institution of Civil Engineers, Great George Street, Westminster, S.W.1, on November 27–28. This conference is intended to review developments in pulverized-fuel firing since the first conference in 1947, and to set the subject in focus against the general background of development in all fuels, including nuclear fuels. Advance copies of papers will be sent to those enrolling with the Secretary, Institute of Fuel, 18 Devonshire Street, Portland Place, London, W.1, to whom all inquiries should be addressed.

The fourth Conference of the International Society of Soil Mechanics and Foundation Engineering will be held at the Institution of Civil Engineers, Great George Street, London, S.W.1, during August 12–24. The papers to be delivered, which have been preprinted in two volumes of Proceedings, are to be discussed in nine sessions, including soil properties and their measurement; techniques of field measurement and sampling; foundations and structures; roads, runways and rail-tracks; earth-pressures on structures and tunnels; and earth dams, slopes and open excavations. Inquiries should be addressed to the secretary, A. Banister, c/o Institution of Civil Engineers, Great George Street, London, S.W.1.

BRITISH ELECTRICAL AND ALLIED INDUSTRIES RESEARCH ASSOCIATION

ANNUAL REPORT

THE chairman of the Council of the British Electrical and Allied Industries Research Association, Mr. F. H. Bramwell, refers in the opening paragraph of his foreword to the annual report of the Association to the loss sustained in the death a little more than a year ago of its director, Dr. Stanley Whitehead. Dr. Whitehead's successor, Dr. H. G. Taylor, took up duty on May 1, 1957, the day of the annual general meeting of the Association.

During the year under review, the Association has transferred the major part of its research activities to new laboratories at Leatherhead, which were formally opened by Lord Mills, Minister of Fuel and Power, on June 26 (see p. 260 of this issue).

The list of reports issued during the year represents all but one of the twenty sections into which the Association's work is divided. Much effort continues to be devoted to work on dielectrics, but it is stated that increasing pressure on the Association to extend its investigations to cover new dielectric materials and processes is tending to reduce the scale and scope of the fundamental work on dielectrics, much of which served in earlier years as the foundation upon which the present developments were based. Intensive study is being given to the factors determining the electric stress at which discharge is initiated in void-free impregnated dielectrics. Work is continuing on the revision of intrinsic electric strength measurement following the discovery, previously reported, of electro-mechanical breakdown. A new investigation is in progress to test a hypothesis suggested by the results of life-tests on paper dielectric capacitors, namely, that one of the factors limiting life is a distribution of weak spots in the dielectric much larger than that corresponding to the known number of conducting particles.

Progress is reported in theoretical work on electronic emission from the metal cathode of an electric arc. The spark discharge in uniform fields is being investigated in relation to formation times by means of a new technique in which a stabilized d.c. supply is used to energize an impulse generator. Further work on gas breakdown at ultra-high frequencies has included measurements in sustained oscillatory fields.

Work on the ratings of transmission and distribution cable includes an extensive programme of field-tests designed to produce data which will enable the fullest utilization of cables to be attained. One aspect of the investigation is the determination of moisture displacement and consequent drying out in the vicinity of loaded cables and the resulting reduction in heat dissipation.

Practical progress in circuit breakers and contactors has resulted from the work on circuit interruption at high vacuum. Work on air-blast circuit breakers has included the study of the voltage distribution across gaps in series in multi-break circuit breakers. Fundamental theoretical work on the electrical and thermal processes of the steady-state arc has suggested that higher arc temperatures occur than had previously been supposed. These predictions, which have been confirmed by spectrographic measurements, have important consequences in relation to the dynamic behaviour of arcs in switchgear.

Progress is reported in the several branches of work on flame-proofness and intrinsic safety. Among these may be mentioned measurements made simultaneously at four points of the transient pressure associated with explosions in the 800 h.p. motor at the Safety in Mines Research Establishment, the machine running at normal speed.

Work continues on the extension of steam tables to 750° C. and 15,000 lb./sq. in., and it is noted that these researches provided a substantial contribution to the Fifth International Conference on the Properties of Steam held in London in July 1956. The programme of work on the creep and corrosion resistance of steel for high temperatures continues, and mention is made that the test rig for the investigation of steampipe welds which was being installed at Brimsdown power station is now in operation.

The Association has long been concerned with work on electrical interference. The authoritative work on inductive interference which has been in preparation for some time is now in process of publication.

In the field of rotating machines, a new theory of tooth ripple flux penetration into laminated pole faces has been developed and has been substantially confirmed by experiment.

The analysis of the behaviour of power systems under steady-state and transient conditions will be greatly facilitated by the completion of the network analyser which is now in partial operation in the new laboratories.

It is interesting to note in passing that the one section of the Association's work not represented by publications is that dealing with the transmission of power at high voltages. Much of the activity of this section has been devoted in recent years to studies of high-voltage direct-current transmission. This work had been in abeyance during the past year, but it may well be that the decision to utilize high-voltage direct current for the cross-Channel power link with the Continent will revive activity in this field.

It is noteworthy that, at the beginning of the report, mention is made of possible future restriction of the Association's development in the absence of increased financial support from industry. The opening of the Association's new laboratories should provide a powerful stimulus to the industry to give increased support to the work of an association which, during the past thirty years, has made a major contribution to the advancement of knowledge and to practice in the electrical engineering field.

J. GREIG

FORESTRY IN THE COMMONWEALTH

THAT forestry, as a serious piece of administration, has been taken up by the British, the annual forestry reports for the Dominions, Colonies and former Colonies or Protectorates give full evidence. As instances, the report of forest administration for 1954–55 for the Western Region of Nigeria (pp. ii + 28. Lagos: Government Printer; London: Crown Agents of Oversea Governments and Administrations, 1956. 9*d*.), and those of the Federation of Malaya, British Guiana and the Sudan may be quoted. From the forestry point of view, the division of Nigeria into three separate regions is unfortunate, since forestry management will become more costly, and for the country as a whole may become more difficult. In a foreword to the report, the Minister of Agriculture deplores the scarcity of suitably educated young Nigerians to fill posts in the Department, and he expresses the hope that the educational facilities at present available will produce candidates capable of taking a forestry degree at a university. A new and important departure is being undertaken in the development of small plantations carrying both timber trees and an under-crop of cocoa or rubber, a notable piece of work which will require a fully trained staff for its supervision. It has recently been decided (Federation of Nigeria. Annual Report on Forest Research and the Forest School, 1954–55. Pp. 16. Lagos: Federal Government Printer, 1957. 9*d*. net) that all aspects of forestry research in Nigeria should be the concern of the Federal Department of Forestry and the application of such knowledge should be the concern of regional departments, the latter being accorded permission to engage in whatever research they desired in accordance with funds available.

The report on the Federal Forest Administration of the Federation of Malaya for 1955 (by D. S. P. Noakes. Pp. ii + 93 + 6 plates. Kuala Lumpur: Government Printer, 1956. 2 Malayan dollars; 4*s*. 8*d*.) is of considerable interest. In spite of the internal troubles of the past years, the Forest Department has been able to proceed with its work, as the first part of the report well shows. It deals with the operations of the Federal Section of the Forest Department, which embrace research, education, engineering (forest), departmental trading in forest produce, local timber supplies and the export trade. The second part treats of the departmental work throughout the Federation.

The report of the Forest Department, British Guiana, for 1955 (pp. 32. Georgetown: Government Printer, 1957) shows the Department still in a difficult stage of progress due to the shortage of senior staff. A development programme is shortly to be introduced, but only one scheme of the Central Timber Manufacturing Plant has proceeded according to plan. It would appear that the most important part of the planning would be for the training of staff for sylvicultural work in the forests. The report for the Sudan (Ministry of Agriculture: Forests Department. Report for the period July 1954 to June 1955. Pp. iv + 75. Khartoum: Department of Forests, 1956) owes much to the work of the former British forest officer. As regards forest policy, the introduction of control of fellings formerly made at will by the population of the country, the prohibition of felling in forest reserves without a licence, and control of fellings for village needs are to the good. These are departures which are essential in the interests of so arid a country as the Sudan and perhaps a native administration has found it easier to introduce them.

The activities of the Forest Research Institute of New Zealand (New Zealand Forest Service. Annual Report of the Forest Research Institute for the year ending 31 March, 1956. Pp. 88. Wellington: Government Printer, 1956) have made continued progress, and two major objectives have been achieved in the completion of field-work for the National Forest Survey of production forests and the formation of the Forest Biology Survey. Sylviculture members of the staff appear to be deficient, a curious anomaly, since sylviculture is the basis of the whole of forestry practice. Requests from conservancies for advice and assistance prove the value of the Institute.

During the past few years, research in forestry subjects has made an impressive advance. If we look to New Zealand, Canada, Australia and South Africa, India, Nigeria, the Sudan, and many other of the smaller forest services, most publish regularly the results of their researches, a service which is of great importance to the progress of forestry and its beneficial influences on mankind as a whole.

THE PHYSICAL SOCIETY

REPORT FOR 1956

THE report of the council of the Physical Society for the year ending December 31, 1956, together with the report of the honorary treasurer and the accounts and balance sheet, were presented to the annual meeting of the Society held at the Science Museum, London, on June 4, and adopted, and the composition of the new council for 1957–58 announced. At the extraordinary general meeting which followed, approval was given for amendments to the articles and rules of the Society to enable the council to elect Fellows without submission of their names to science meetings of the Society.

Immediately afterwards, Prof. N. F. Mott delivered his presidential address entitled "The Physics and Chemistry of Metals", in which he described how physical techniques are contributing to an understanding of the nature of the metallic bond. Measurements of diamagnetism and of conductivity at high frequencies and low temperatures enable an experimental determination to be made of the form of the Fermi surface, which indicates how much the form of the electronic wave functions varies with direction. The behaviour of the magnetic electrons in nickel and iron was contrasted. In nickel the *s* and *d* bands overlap and both contribute to the Fermi surface; in iron the magnetic electrons do not contribute to the Fermi surface or to the conductivity. Finally, the effect of chemical or binding forces on mechanical properties was discussed.

The report comments on the way in which the form of the Society's science meetings has altered in the past few years, from meetings devoted to the reading of papers submitted for publication in the Society's journals to short conferences on specific subjects at which papers are presented bearing on aspects of the subject but not necessarily describing work sufficiently advanced for publication. Four such conferences were held during the year: "Cloud

Physics", jointly with the Royal Meteorological Society, during January 4–5; "Semiconductors", in conjunction with British Thomson-Houston Research Laboratories, during April 10–12; "The Physics of Gas Flow at Very High Speeds", at the University of Manchester, during July 16–17; and "β- and γ-Ray Spectroscopy and Related Topics", at the University of Edinburgh, during December 17–19. It is planned to hold six or seven conferences annually. The arrangement to hold joint colloquia on electron physics open to members of the Institute of Physics and of the Society was continued, and two meetings were held. The annual Fellows' luncheon, which was attended by about one hundred Fellows, was again held on the opening day of the annual exhibition of scientific instruments and apparatus. The fortieth Guthrie Lecture was delivered by (the late) Sir Francis Simon, who gave a historical survey of the third law of thermodynamics, and the eighth Rutherford Lecture by Prof. P. I. Dee, who spoke on the alpha particle.

Prof. J.-P. Mathieu was the recipient of the eleventh Holweck Medal of the Société Française de Physique and the Holweck Prize of the Physical Society; after the presentation, which took place in London, Prof. Mathieu delivered the Holweck discourse on the subject of crystalline structures. Prof. J. G. Daunt (Ohio State University) received the thirty-third Duddell Medal and for his address discussed the magnetic refrigerator for temperatures below 1° K. (now published in *Proc. Phys. Soc.*, B, 70, 641; 1957). The twelfth Charles Vernon Boys Prize was presented to Prof. G. D. Rochester and Dr. C. C. Butler in recognition of their work on the discovery of the charged and uncharged V-particles.

During 1956, the Council states, there was a slight increase in the total membership, from 1,978 to 1,999. There was an overall surplus for the year of just over £1,000, indicating the healthy condition of the Society's finances, and this is emphasized by the balance sheet, which shows that the Society's investments, apart from special funds, total more than £20,000. Expenditure on behalf of the members exceeded income by about £700, and on general activities, consisting mainly of publications and science meetings, the Society incurred a loss of nearly £1,200 in spite of a generous grant of £1,500 from the Royal Society. However, as in former years, the annual exhibition of scientific instruments and apparatus, through the success in sales of the handbook to the exhibition, brought in a revenue which more than counterbalanced the losses. Both halls of the Royal Horticultural Society were used for housing the exhibition. The number of exhibitors was substantially the same as in previous years and the attendance was again large—more than 16,000.

Greatly increased interest in the Society's publications during the year is reported. The sale of the current numbers of both the *Proceedings of the Physical Society* and the "Reports on Progress in Physics" has risen, and there has been a large increase in the sale of earlier volumes of the "Reports" and of some of the Society's special reports, particularly the 1954 Bristol conference report on "Defects in Crystalline Solids" and the 1954 Cambridge conference report on the "Physics of the Ionosphere". A serious delay because of printing troubles in the publication of the *Proceedings* during the earlier part of the year has since been made up. Two hundred papers and 111 research notes and letters were accepted for publication; 45 were rejected or withdrawn by the authors. Vol. 19 of the "Reports", containing nine specialist articles, was issued during the summer and separate copies of the individual articles were again available for purchase.

Details of the activities of the four Groups of the Society, the Colour, Optical, Low Temperature and Acoustics Groups, together with a list of the numerous bodies on which the Society is represented, are given in the annual report. In addition to science meetings, the Optical Group held its summer meeting at the University of Exeter; the Low Temperature Group held an all-day discussion meeting on the subject of liquid helium, and a two-day joint conference with the X-ray Analysis Group of the Institute of Physics at the Clarendon Laboratory, Oxford, on the subject of X-rays and low-temperature crystallography, and visited the Low Temperature Laboratories of the Royal Radar Research Establishment, Great Malvern; and the Acoustics Group included in its programme a symposium on loudspeakers and a distinguished visitor's address by Dr. W. E. Kock.

The officers and council for 1957–58 are as follows: *President*, Prof. N. F. Mott; *Vice-Presidents* (in addition to those who have filled the office of president), Prof. S. Devons, Prof. F. Llewellyn Jones, Prof. H. Jones and Dr. K. Mendelssohn; *Honorary Secretaries*, Dr. C. G. Wynne and Dr. H. H. Hopkins; *Honorary Foreign Secretary*, Prof. E. N. da C. Andrade; *Honorary Treasurer*, Mr. A. J. Philpot; *Honorary Librarian*, Dr. R. W. B. Pearse; *New Ordinary Members of Council*, Dr. B. H. Flowers, Prof. M. H. L. Pryce and Mr. E. W. H. Selwyn.

WATER POLLUTION RESEARCH

THIS review of the report of the Water Pollution Research Board for 1956[*] could start with a frequently quoted verse from Gray's "Elegy" about gems and flowers, though some might find odd the juxtaposition of any thought from that poem and sewage. The point is that this publication is of a kind liable to be ignored by most not directly concerned with pollution on the grounds that it is of interest only to those who are, which is not true. The reviewer deems it his function to show where and why this is not true even if, in dwelling on those pieces of research that will command interest outside the applied field, he gives an unbalanced picture of the work of the Laboratory.

The concentration of oxygen is one of the important factors affecting freshwater organisms, but one of which the significance is very hard to assess because it often fluctuates considerably and often reaches critical values at the most inconvenient times of day. Any method of recording it continuously will be welcomed by many concerned with both theoretical and applied problems; the Water Pollution Research Laboratory has devised two. The first required mains electricity which limited its range rather seriously. The second, referred to in the report under review, can be operated from batteries.

The results of what must clearly have been an extensive series of trials are summarized in a table which shows at three temperatures the highest concentration of oxygen at which all fish died in a week and the lowest at which all survived for a week. Most oxygen was required at the highest temperatures, and rainbow trout generally needed more than any of seven species of coarse fish tested, which is just what anyone would have foretold. Other results are more unexpected; for example, trout survived for a week at a temperature of 20° C. when the concentration of oxygen was only 29·6 per cent of saturation, and the most exigent species at this temperature was mirror carp, which required 58·9 per cent. Another surprise is the smallness of the difference between the two figures; at 20° C. the oxygen concentration had only to drop to 28·2 per cent of saturation and no trout survived for a week. There is much in this table for physiologists, ecologists and those charged with the care of fishing waters.

[*] Department of Scientific and Industrial Research. Water Pollution Research 1956: the Report of the Water Pollution Research Board with the Report of the Director of the Water Pollution Research Laboratory. Pp. iv+75+4 plates. (London: H.M. Stationery Office, 1957.) 4s. net.

The aerating effect of weirs has been studied, and it has even been possible to find a formula for it.

The rest of the report will interest mainly those directly concerned with pollution problems. An extensive survey of the Thames estuary has been made to discover the amount of oxygen that combines with polluting matter and the amount taken by the water from the air, together with the influence of temperature, rate of flow and tidal phenomena on these two processes. The hope was that it might be possible to find general principles from which the effect of the last three on the first two could be predicted. An observer knowing the rate of flow, the temperature, and the state of the tides, which are easily measured, could then say how much polluting matter could be discharged into the stream without causing total oxygen deficiency and nuisance anywhere. The hope has been fulfilled.

Uptake of oxygen is reduced by synthetic detergents, though the effect diminishes as the concentration of sewage rises. Cetyl alcohol, which is being added to reservoirs in certain parts of the world to see whether it will reduce evaporation, also depresses the rate of oxygen uptake. Substances added to prevent foaming in activated sludge plants do not.

Work on oxygen has been the main preoccupation at the laboratory, experience having shown that the best policy is to keep the field of effort narrow, but much else has been accomplished as well. The toxicity of various substances to fish has been investigated. That of synthetic detergents is reduced by the activated sludge process. Ammonia occurs frequently in polluted waters and, in those charged with sewage, may be the main killing agent beyond the zone where lack of oxygen is acute. Concentrations of 10–15 parts per million N ammonia affect fish survival considerably. It occurs, too, in effluents resulting from the washing of coke oven gas together with phenol, which is less toxic. The effect of the two substances is complementary, and the toxicity can be calculated when the proportion of the two is known.

When the new Laboratory was being planned, a site to which large amounts of domestic sewage could be supplied was chosen. Research making use of this facility is following two lines: the elucidation of the fundamental nature of certain processes that are still largely empirical in operation; and methods of treating different kinds of effluent. To the first category belongs a study of the structure of the biological film of a percolating filter and of factors which modify it; the reviewer wonders whether much progress will be made with this until more precise names than 'zoogloeal bacteria', 'nematodes' and 'protozoa' can be given to the organisms involved. What exactly happens during the activated sludge process is another thing that the staff intend to find out.

T. T. MACAN

TASTE AND SMELL

THE senses of taste and smell from the physiological and psychological points of view formed the subject of one of the periodical discussion meetings at the Society for Visiting Scientists, London, on May 21. The degree of attention paid during the general discussion to psychological rather than to physiological factors might be held to indicate that, in certain circumstances at least, the scientist was just as interested in his own subjective psychological processes as in the pursuit of objective data. Dr. H. Kalmus (University College, London), one of the three opening speakers, began by sketching-in some of the anatomical and physiological background of the receptor organs for taste and smell and then went on to describe some of his own work and that of his associates in this field. Following up the earlier discovery that phenylthiourea tastes bitter to some people but is apparently tasteless to others, and that this varying power of perception was hereditary, Harris and Kalmus had shown that this simple genetical difference applies, in fact, to a large group of substances containing the CNS group but to no others. In a second line of work, using a series of feeding experiments with two hives of bees and two different food sources, in which use was made of the dancing motions of bees as a method of information transference, Kalmus, together with C. R. Ribbands, had succeeded in confirming von Frisch's discovery that the bees were able to distinguish the taste of bees from their own hive from that of those from the other hive. In this case, however, the power of distinction was not hereditary. Dr. Kalmus had also worked on the power of odour perception in dogs. He had demonstrated that a dog which had been given the scent of a man's hands could successfully recover a handkerchief scented in the man's armpit from a number of other handkerchiefs scattered about the room, and could trace the man across a field in the open air from the scent left on a handkerchief when the trail was confused by a number of other men. In trials indoors with identical twins the wrong twin might be followed instead of the right one, though in the open air there was some indication that the right twin might be followed in preference. The most interesting point here seemed to be that the dog could recognize a man from his armpit odour (on the handkerchief), having previously been given only the hand odour, whereas to a human being there seemed to be more resemblance between two different armpit odours than between the hand and armpit odours of the same individual. This seemed to indicate a different and perhaps altogether higher power of integration in the dog; Mr. B. Babington Smith used the illuminating analogy of a musician who might recognize that two sounds apparently different to a non-musical ear were in fact merely octaves of the same note.

Mr. Babington Smith (Institute of Experimental Psychology, Oxford), the second speaker, described some work on non-expert consumer preference panels composed of undergraduates, in which he had been interested rather in the methodology and in the reactions of his subjects than in the actual results of the tests. The tests were confined to simple paired comparisons on red wine and chocolate, though Mr. Babington Smith did not stress the actual results beyond rather mischievously suggesting that there was some indication that the more intelligent people preferred plain to milk chocolate. The incidental results were more illuminating. Though consistency was generally aimed at, an individual's reactions, it appeared, were seldom completely consistent and might be based on changing standards as the trial proceeded. The order in which the material was presented might be important, and there was also a problem in the actual quantity of the test material that should be provided. It was possible that the subject might learn about the technique of making comparisons as the test proceeded, and also that an initial preference might turn almost to nausea before the trial was over. Mr. Babington Smith distinguished between 'competitors' and 'co-operators' among his subjects; the former seemed anxious to find what they felt to be the 'right' answer, whereas the latter did more nearly what they were asked, which was to provide a straightforward description of their reactions. The first type might be useful on expert tasting panels, and the second, who might perhaps be regarded as having the instincts of a gourmet, would be useful in a consumer tasting panel.

Several speakers in the subsequent discussion were not happy about this classification. Mr. Babington Smith indicated that he did not intend a rigid classification into psychological types, his description only applying within the framework of the experiment; he also agreed that there might be a tendency for the less-experienced tasters to be anxious to find the 'right' answer, whereas the more experienced individual was more likely to be relaxed and confident in his appreciations.

The third main speaker, Mr. W. J. Gleeson (Reckitt and Colman, Ltd., Norwich), described a problem on market research for a food manufacturer. This was admittedly in the strict sense an unscientific business, but it was demonstrably possible for consumer surveys of this kind to convey information of which the manufacturer was not aware, and to indicate that the consumer had detected something that the manufacturer had not expected him to notice. The consumer in any event liked to be asked his opinion and would volunteer it even if he was not asked; and so they asked him. One of the principal difficulties in this type of work arose from the fact that the consumer would subsume all the factors affecting his preference, even colour, into the omnibus expression 'flavour'. Other difficulties arose from the necessity to compensate statistically so far as possible for the kind of error-inducing factors which had already been described by Mr. Babington Smith.

During the general discussion, some attention was given to the inevitability, or desirability, according to one's point of view, of using a combination of two or more of the senses in arriving at a subjective judgment of quality. In this connexion, Prof. H. D. Kay (National Institute for Research in Dairying, Shinfield) referred to cheese, Dr. H. J. Strauss (consultant chemist) to essential oils, and Mr. H. J. Bunker (consultant microbiologist)—who started with the story of the small girl who said she could hear the bacon smelling—to beer. Mr. Bunker's work, in contrast to most of the rest, was concerned with expert tasting in pursuit of the maintenance of a standard rather than with consumer preferences. In his field, the powerful assault of hops on the palate provided one of the major difficulties to extended tasting tests. Dr. G. Slot (physician) referred to the deliberate addition of emotional overtones to consumer preference, and instanced his hospital patients, who greatly preferred an expensive but widely advertised glucose drink to his own free prescription for the same material, as well as to those patients who reacted quite differently to red pills and blue pills even when both were aspirin. Mr. R. B. D. Stocker, as a dentist, picked up a reference made by Mr. Gleeson to fashions in taste, and said that in recent years the public taste had changed in a manner inimical to health. Mr. J. M. Harries (Ministry of Agriculture, Fisheries and Food) emphasized that one should not accept a stated preference as valid unless one had previously established the subject's ability to differentiate between the materials on trial, and Dr. Hugh Davson (University College, London) expressed the distaste of a physiologist for experiments in which the subject was asked to express a preference as opposed to those in which he was merely asked if he could tell the difference between two stimuli. Perhaps the last word lay with Dr. Kalmus, who thought that the whole subject would probably remain largely empirical and that it would be a long time before any sweeping, unifying theory emerged.

D. Neville-Jones

USE OF ISOTOPES IN AGRICULTURE

THE European Contact Group on the uses of isotopes and radiation in agricultural research has been established by the Food and Agriculture Organization of the United Nations to provide a medium for the exchange of information between European countries on present and planned programmes with the view of identifying applications likely to be of greatest significance for European agriculture. The object is to enable countries to pool their knowledge and experience for the common good and to make most effective use of the facilities available. The first meeting took place at Wageningen, in Holland, during December 10–14, and a report of the proceedings has recently been published*. It was attended by thirty-one representatives of sixteen European member governments and by observers from the United States and the U.S.S.R. and eight international organizations. Dr. S. L. Mansholt, Minister of Agriculture, Fisheries and Food in the Netherlands Government, announced that his Government had decided to establish an institute at Wageningen for the application of atomic energy in agriculture and as a centre of research, instruction and information. He expressed the hope that this would not remain a purely national institute, but would in due course develop into a European centre for the application of atomic energy in agriculture.

Discussions on the use of isotopes and radiation in agricultural research were organized under five subject headings. The topics concerned with the use of isotopes in soil science included the validity of the isotope technique, determination of active fractions of various soil ions by the isotope-dilution technique, use of labelled fertilizers, vertical migration of soil ions, exchange of ions between roots and medium, and evolution of organic matter in the soil. The delegations described how isotopes are being used in plant science to study such subjects as absorption of ions by leaves, uptake of minor elements, photosynthesis and sap movement in trees. The use of isotopes in animal science fell approximately into four categories, namely, intermediary metabolism, mineral metabolism, endocrinology and reproduction.

---

* Food and Agriculture Organization of the United Nations. European Commission on Agriculture: Sub-Commission on Agricultural Research. Report of the First Meeting of the European Contact Group on the Uses of Isotopes and Radiation in Agricultural Research, held in Wageningen, Netherlands, 10–14 December, 1956. Pp. ii+30. (Rome: Food and Agriculture Organization of the United Nations, 1957.)

The fact that the genetic materials—the genes and chromosomes—are highly sensitive to ionizing radiations which induce hereditary changes or mutations has led to the exploration of the possibility of using this technique in improvement of crops. So far the method has been little used in animal breeding. The delegations indicated that useful mutations of cereals and other crops were being obtained.

The Group also discussed the reports which several countries presented on the use of radiation in the preservation and processing of food. This work is still in the developmental stage, and important problems need further investigation. At the moment, the destruction of insects in stored products, the suppression of sprouting in potatoes and root crops and the treatment of some fresh meats would appear to be the most promising applications of ionizing radiation to foods.

The nature of the financial provisions required for research programmes involving the use of isotopes and radiation was discussed, and the delegations made statements on the scope of training facilities for isotope research. Consideration was also given to the design and equipment of isotope laboratories for agricultural research. Attention was directed to the need for an international list of available labelled compounds. For the future, the Group agreed to continue its activity in organizing special meetings or symposia in particular aspects of soil science, plant science, plant breeding, animal science and use of radiation in food preservation.

SCHOOL NATURAL HISTORY SOCIETIES

THE value of voluntary societies to the corporate life of the school and its fuller development is well brought out in three recent reports. The first, from Blundell's School, gives details of special Sunday evening lectures which are arranged by the Science Society and to which speakers of distinction have been invited over a period of many years. The hundredth of the meetings was celebrated during the year under review when the Society proudly welcomed back Mr. W. H. Dowdeswell, who had had much to do with the Society's foundation.

The role of the society in stimulating the pursuit of knowledge and truth for their own sakes is shown by the original investigations which form the bulk of the report. J. H. Becket describes observations made on catches in moth traps placed at ground-level and at a height of 80 ft. An account of experiments to compare soil temperatures under glass and polythene cloches with that of unprotected soil is given by W. L. Slater, while investigations of the flora of the Grand Western Canal are examined by C. Little. How woodlice maintain themselves in a moist environment has been investigated by A. J. S. Wearing; A. Lamb gives an account of the efficiency of the pollination mechanism in *Arum maculatum*. There is also a description of pollen and pollination in rhododendrons by A. Ridge.

Much of the report of the Rugby School Natural History Society is taken up with an account by J. A. D. Hope of his ornithological observations on the Isle of May for a short period in 1956. Hope was primarily concerned with records of the plumage and characteristics, voice and behaviour of the shag, the kittiwake and the fulmar; his essay is not unworthy of much more experienced ornithologists. Besides details of special lectures, the report contains information about the activities of the many sections comprising the Society. These include the museum, vivarium, library, zoological and entomological section; affiliated sections, the proceedings of which are described, include architecture, meteorology, photography, astronomy, railways, wireless, aeromodelling and philately. The Society has much to be proud of.

This is also true of the Oundle School Natural History Society, the report of which is mainly concerned with records of mammals, birds, fish, butterflies and moths, dragonflies, rotifers, crustaceans and plants observed in the neighbourhood of Oundle. An interesting account of laboratory animals shows that axolotls, African clawed toads, stick insects, salamanders, eyed lizards and geckoes, various British lizards and tropical fish were all under observation some time during 1956.

OXFORD BOTANIC GARDEN

THE Botanic Garden at Oxford, which is the oldest in Britain, was founded and endowed as a Physic Garden by the Earl of Danby in 1621. The Garden was intended for "the improvement of learning" with special regard for the study of 'simples' or drug plants. It was laid out on the site of the old Jews' burying ground opposite Magdalen College, from which the Garden is still leased by the University.

In 1642 the Garden was ready, and Danby, having failed to secure the services of the King's gardener, John Tradescant, appointed Jacob Bobart, an old Brunswick soldier, as 'Keeper'—indeed, as 'Hereditary Keeper'. During the difficult years that followed, Bobart began to collect garden plants, mainly for their interest in medicine, and in 1648 he published a catalogue of 600 native British plants and twice as many from abroad.

A professor of botany was appointed by Charles II in 1669 but the post was not endowed, and the care of the Garden and even the duties of teaching largely lay in the hands of Bobart and later of his son; the younger Bobart made some of the first experiments on sexual reproduction, using male and female plants of the indigenous campion. Many of the plants that he cultivated, especially West Indian ferns, are probably growing in the Garden to-day.

Fifteen years after the death of Bobart a chair of botany was finally endowed by William Sherard. The new professors followed the custom of the century rather than the example of Bobart: teaching ceased. The herbarium grew, but the plants were neglected. In these circumstances, it was by instinct rather than by instruction that Gilbert White, the naturalist, and Sir Joseph Banks, who later founded and stocked the gardens at Kew, visited the Physic Garden as undergraduates and gained a not too favourable impression of botany as a systematic study.

More than a hundred years' passed and the Garden was then put in charge of an energetic and versatile man who had new ideas about many things, including plants and gardens; in 1834 Charles Daubeny became professor of botany. He changed the name to Botanic Garden. He rebuilt the glasshouses and he replanned the beds. He made new collections of plants in their economic, historical and geographical relations, and he raised trees from seed sent to him by collectors in America, India and China, trees which may still be seen in the garden. He wrote a Guide to the Garden which appeared in three editions, built an official residence for the professor next to the Danby Gate, and he set up a fountain and two aquaria. One of Daubeny's activities reached out to a larger and later world. On the land adjoining the river, he laid out experimental plots designed to show the value of mineral fertilizers. Their effect was to inspire one of his pupils, John Lawes, to found what is now the Rothamsted Experimental Station. Daubeny gave the place a new name, and he also gave it a new purpose.

The past hundred years have seen another kind of transformation in the character of the Garden. It has been during this time that, by breeding wild plants and selecting their progeny, our modern garden flowers have been created. The wild parents were largely the 7,000 exotic species brought into our botanic gardens during the reign of George III, or more precisely, during the life of Sir Joseph Banks. In one year, 1789, there arrived in the Port of London *Rosa chinensis* and *Chrysanthemum indicum*, the parents of all our modern roses and chrysanthemums. The new plants are represented by these and by all the asters and dahlias, irises and narcissi of our outdoor gardens, the begonias, pelargoniums, fuchsias and orchids of our glasshouses. The result of this new experimental horticulture can be seen in any flower show. In the Botanic Garden the stages in its history, which are quickly lost and forgotten elsewhere, are carefully and fortunately preserved.

An account of the Garden as it exists to-day has been prepared by the keeper, Prof. C. D. Darlington, and the superintendent, G. W. Robinson*. It contains details of the more interesting plants, when they were planted, and where they came from. All botanists would be glad to possess it.

T. H. Hawkins

ADAPTIVE RADIATION OF TRAPDOOR SPIDERS

THE spiders of the tribe Aganippini show a striking sequence of adaptation to habitats ranging from moist forest situations to desert environments. These have been investigated in Western Australia by Barbara Main (*Austral. Mag.*, 12, No. 5; March 1957).

The aganippinid spiders show a sequence of adaptation, represented by three dominant levels corresponding with a change from a moist to a dry environment. Associated with the change in habitat the spiders exhibit two main lines of adaptation. The first is associated with the reduction of water loss through the cuticle and the second is directed towards a more efficient feeding method when food is sparse. A thick abdominal cuticle, possessed by certain species, prevents loss of moisture from the body. *Idiosoma nigrum*, for example, has a tough, spiny, sclerotized abdomen in contrast to the soft, hairy abdomen of *Aganippe latior*.

Spiders which live in habitats having an abundant food-supply, such as the moist situations of litter formed from the wide flat leaves of such trees as eucalypts and banksias and which have the burrow opening among the litter, seize their prey from within reach of the burrow entrance but without emerging. Similarly, spiders occupying creek banks and claypans seize prey within reach of the burrow. Spiders in dry environments, however, such as the dry habitats around the bases of casuarinas and acacias, have a different technique of prey capture. These animals collect twigs and attach them singly, with silk, in radial arrangement, to the rim of the burrow. The twigs are then used as 'feeling-lines' for detection of prey. Spiders have been observed sitting in the burrow with the tips of the legs on the rim-ends of the twigs. Movements of insects on the twigs stimulate the spiders to run out of the burrow along the twigs in pursuit; in this way the spider greatly increases the area from which it can obtain prey.

Associated with the different methods of feeding, which varies in the distinct habitats, there are certain types of structure which represent three adaptive levels. The 'moist-dwelling' spiders have the head raised and sloping in such a way that the small, widespread eyes are directed only to the front. The poor eyesight of these animals is associated with the fact that in the litter they would be unable to see prey at any distance. Such animals also have short stout legs, adapted for supporting the thickset body within the burrow.

Spiders inhabiting bare-ground situations have moderately enlarged eyes, which is associated with seeing their prey in the open. The legs of these spiders are slightly longer and thinner than 'moist-dwelling' spiders; this is advantageous for quick movement partly outside the burrow.

'Twig-lining' animals have a flattened carapace enabling the eyes, which are greatly enlarged, to see in all directions. This is of great advantage when pursuing prey for some distance from the burrow. The legs are long and slender, adapted for running quickly on the flat surface outside the burrow.

Not only are the behaviour and body structure of the animals modified in adaptation to the different habitats, but they also construct different and characteristic types of doors to the burrows. Dwellers in moist habitats have thin, fragile doors made of silk-bound litter fragments. Those in open situations have soil doors; if in creek banks, the doors are thin and flaplike, whereas in claypans doors are thick and cork-like. Such a cork-like plug prevents the burrow being flooded when the bare ground is inundated after rain. Finally, 'twig-lining' spiders, which run out of their burrows to catch prey, construct thin, wafer-like doors of litter fragments that are very light in weight and stand open unsupported when flung up as the animal pursues its prey.

It is interesting that the various species, representing different adaptive levels, have apparently been derived from a common ancestor by its expansion into several types of habitat, where genetic recombination and natural selection have operated to produce forms which are modified, behaviourally and structurally.

VISUAL PIGMENT OF A DECAPOD CRUSTACEAN: THE LOBSTER

By PROF. GEORGE WALD and DR. RUTH HUBBARD

Biological Laboratories, Harvard University, Cambridge, Mass.

THREE animal phyla have developed well-constructed, image-forming eyes: vertebrates, molluscs, and arthropods. Among the molluscs, the visual system of the squid has been examined extensively[1]; and recently Kampa has described a photosensitive pigment ('euphausiopsin') from the eyes of certain euphausiid crustaceans[2]. The present communication describes the photosensitive pigment from the eye of a decapod crustacean, the lobster (*Homarus americanus*).

Nine-tenths of all the vitamin A that a lobster possesses may be concentrated in its eyes[3]; and virtually all this is in the form of the hindered *cis* isomer, neo-*b* (11-*cis*), the precursor in vertebrate eyes of rhodopsin and iodopsin[4]. In addition to vitamin A, the lobster eye contains large quantities of astaxanthin, and small amounts of other coloured carotenoids[4].

The animals used in this investigation had not been dark adapted. The eye stalks were removed under room light, and stored up to four months at −15° C. Preparatory to extraction, the eye was cut away from the body of the eye stalk with a razor blade. This and all subsequent operations were performed in dim red light.

In preliminary attempts to extract visual pigment, the whole eye tissue was used. Though this was extracted repeatedly with petroleum ether and aqueous buffers to remove light-stable pigments, the photosensitive pigment when finally extracted with digitonin was accompanied by so much protein-bound astaxanthin as to interfere seriously with its measurement.

The electron microscopy of insect eyes has shown that the rhabdomeres of arthropod ommatidia possess a highly regular microstructure, reminiscent of the outer segments of vertebrate rods and cones[5]. Like the latter, arthropod rhabdomeres probably contain the visual pigments; and their similarity in microstructure implies an essential similarity in chemical composition. In any event, this notion encouraged the attempt to isolate lobster rhabdomeres by using methods which had already proved successful in isolating the outer segments of vertebrate rods and cones[6].

Freshly excised eyes were thoroughly ground with mortar and pestle in small portions of 45 per cent sucrose in $M/15$ phosphate buffer, pH 6·5, to a final volume of 20 ml. The tissue suspension, in a centrifuge tube, was layered over with $M/15$ phosphate buffer, and spun in the 'Spinco Preparative' ultracentrifuge at 30,000 rev./min. for 15 min. A fine layer of tissue fragments, composed in part of rhabdomeres, floated in the interface between the sugar and buffer solutions. The remaining eye tissues were sedimented. The supernatant was stirred up to disperse the floating tissue, and poured off. The sediment was ground again in 45 per cent sucrose, centrifuged, and the interfacial tissue treated as before. This procedure was repeated twice, making a total of four such flotations. The combined rhabdomere suspensions, having been diluted further with buffer, were sedimented in the centrifuge. The supernatant, bright red-orange in colour from its content of protein-bound astaxanthin, was discarded.

The rhabdomere tissue was re-suspended in $M/15$ phosphate buffer, pH 6·5, and centrifuged for 30 min. at 12,000 rev./min. The supernatant, now only faint red-orange in colour, was discarded. The sediment was lyophilized, and the dry residue extracted four times by stirring with petroleum ether. The first such extract was bright orange in colour, the last colourless. The sediment was dried under suction, extracted in the cold with $M/15$ phosphate buffer, pH 6·5, and centrifuged. The faintly yellow supernatant was discarded. The sediment was resuspended in distilled water and re-centrifuged. The supernatant, now entirely colourless, was discarded. The sediment was stirred into 1 ml. of 2 per cent unbuffered digitonin and allowed to stand over night. The extract was cleared by centrifuging at 30,000 rev./min. for 15 min.

The absorption spectrum of a portion of this extract, brought to pH 9·3 with sodium carbonate, is shown in Fig. 1, curve 1. It displays a maximum near 500 mμ, and absorption which rises into the ultraviolet. The spectrum was recorded to 310 mμ, though this portion is not shown in Fig. 1. This solution was exposed for 1 min. to the light of a microscope lamp passing through an orange Corning 3482 filter. The spectrum, recorded 2·5 min. later, showed that a photoproduct had formed, lying at shorter wave-lengths than the original pigment, and possessing a higher absorption maximum (curve 2). The solution was now left in the dark, and its absorption spectrum recorded periodically. The absorption fell regularly in the neighbourhood of 490 mμ, and rose in the neighbourhood of 370 mμ, marking the formation of retinene.

When the dark reaction had been completed (curve 11), a small inflexion remained near 480 mμ, caused by the presence of a trace of astaxanthin. The flotation procedure had eliminated nearly all this contaminant.

To the solution of curve 11, hydroxylamine was added to a final concentration of 0·1 M. Hydroxylamine takes retinene away from its fortuitous combinations with other amino-compounds, to form the single product, retinene oxime. The spectrum of this substance does not change with pH, and possesses virtually no absorption at wave-lengths longer than 450 mμ[7]. For these reasons, difference spectra computed by subtracting the spectrum of the hydroxylamine-treated product from curves 1 and 2 of Fig. 1 also are independent of pH, and above 450 mμ have the force of true absorption spectra.

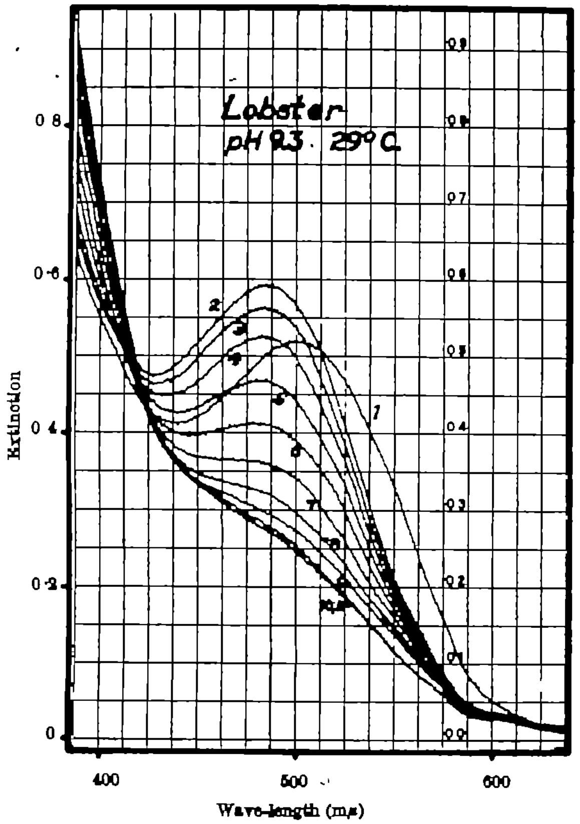

Fig. 1. Absorption spectra, recorded photoelectrically, of a preparation of lobster rhodopsin and the course of its bleaching (pH 9·3, 29° C.). Curve 1 shows the spectrum of the original preparation, measured in the dark. The solution was irradiated for 1 min. with bright orange light, and its absorption spectrum recorded at once (curve 2; 2·5 min.) and periodically thereafter in darkness: (3) at 8 min.; (4) at 16·5; (5) 31·5; (6) 50·5; (7) 84·5; (8) 135; (9) 190; (10) 232; and (11) at 254 min. from the start of the irradiation. The far ultra-violet portions of these spectra are omitted; they were recorded to 310 mμ.

Such difference spectra are shown in Fig. 2. The photosensitive pigment possesses an absorption maximum ($\lambda_{\text{max.}}$) at about 515 mμ. For the present we shall call this pigment 'lobster rhodopsin'.

On irradiation, the extinction rises and $\lambda_{\text{max.}}$ is displaced to about 490 mμ. The photoproduct resembles what we have called metarhodopsin, an orange intermediate in the bleaching of vertebrate rhodopsin[9]. Like the lobster photoproduct, the absorption of vertebrate metarhodopsin lies at shorter wave-lengths than rhodopsin, and in certain cases it possesses also a higher extinction. Lobster metarhodopsin, however, is very much more stable than vertebrate metarhodopsin. To obtain a record of vertebrate metarhodopsin comparable with Fig. 1 or 2 we have had to work at about − 20° C.; whereas the lobster measurements were made at about 29° C.

In the dark, lobster metarhodopsin, like the vertebrate photoproduct, goes over to a mixture of retinene$_1$ and opsin. The rise of absorption on bleaching, shown in Fig. 1, is maximal at about 370 mμ, the $\lambda_{\text{max.}}$ of retinene$_1$ in such preparations at pH 9·3. Retinene$_1$ oxime in digitonin solution has $\lambda_{\text{max.}}$ 362 mμ, corresponding with the minimum in the difference spectrum shown in Fig. 2. The identity of the retinene was further established by extracting it from a solution of bleached lobster rhodopsin, and mixing with antimony chloride. A dominant absorption band appeared at about 650 mμ, moving within 30 sec. to 664 mμ; this behaviour is characteristic of retinene$_1$. A small amount of vitamin A$_1$ also was present. The lobster retina contains such large amounts of vitamin A that the trace found in these extracts probably represents only a contaminant.

The conversion of lobster metarhodopsin to retinene and opsin follows the course of a first-order reaction. At pH 9·3 and 29° C. (Fig. 1), the time for half-completion of this reaction is 43 min., and the first-order constant, k, is 0·016 min.$^{-1}$. This reaction proceeds in the same manner also at pH 6·5.

In such extracts as these, the mixture of retinene$_1$ and opsin is the final product of bleaching. If to this final solution one adds a granule of potassium borohydride, the retinene$_1$ is promptly reduced to vitamin A$_1$. Whether this reaction also occurs enzymatically in the lobster eye remains to be determined. The large amounts of neo-b vitamin A normally present in the eye imply that this substance is the precursor of lobster rhodopsin, and make it probable that, as in vertebrates, the rhodopsin takes part in a retinal cycle[9] which includes vitamin A.

We have referred to the lobster visual pigment as a rhodopsin, following a usage suggested some years ago, according to which all vertebrate rod pigments which have retinene$_1$ as prosthetic group are called rhodopsins, and are designated further by the name of the animal of origin[10]. Since the pigments of the lobster and squid are so similar to vertebrate rhodopsins in composition and properties, we call them also 'rhodopsins'. We suggest that this nomen-

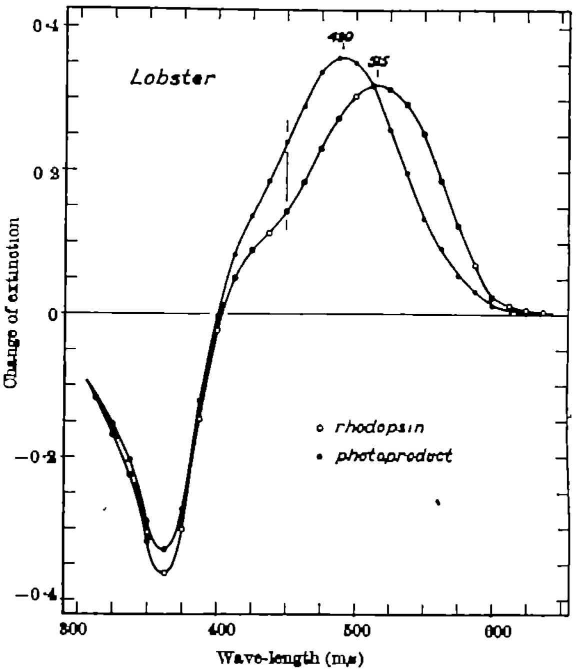

Fig. 2. Difference spectra of lobster rhodopsin and of an early product of its irradiation (photoproduct). These were obtained by subtracting from curves 1 and 2 of Fig. 1 the absorption spectrum of the final product of bleaching (curve 11), after treatment with hydroxylamine to convert retinene to retinene oxime. Since retinene oxime has virtually no absorption above 450 mμ, the difference spectra are equivalent to true absorption spectra above this wave-length, marked in the figure with a vertical line. Lobster rhodopsin has λ(max.) 515 mμ, the photoproduct λ(max.) 490 mμ; and the minimum at the left corresponds to the absorption maximum of retinene oxime at 362 mμ

clature be retained until a wider survey of vertebrate and invertebrate pigments has been accomplished. It may then appear that further designations are useful, based upon whatever general distinctions have emerged. At present, however, the attachment of specific designations to each invertebrate pigment to be extracted ('cephalopsin', 'euphausiopsin') can only lead to confusion. It is easier to make new nomenclature than to get rid of old. The less nomenclature we make now, the less we shall have to regret later.

This investigation was supported in part by funds from the Rockefeller Foundation and the Office of Naval Research. We are indebted to Mr. Stanley Burg for gifts of lobster eyes.

DIRECTIONS OF MAGNETIZATION IN THE CARBONIFEROUS GLACIAL VARVES OF AUSTRALIA

By E. IRVING

Department of Geophysics, Australian National University, Canberra

THE varved sediments in the Upper Kuttung Series of New South Wales have some interesting magnetic characteristics. Their average magnetic inclination is 84°, indicating that they were deposited in a high latitude and is therefore in agreement with their glacial origin. The pole positions consistent with their average direction of magnetization are near Lord Howe Island and Madeira, and are a very long distance away from equivalent determinations from Britain and the United States.

Varves were laid down in lakes in the vicinity of glaciers under conditions favourable to their becoming magnetized parallel to the geomagnetic field at the time of deposition. Their year-by-year banding allows samples to be taken in a known time sequence so that the secular variation of the field can be studied. Extensive work on Pleistocene and Recent varves[1] has provided information about the average direction and variation of the geomagnetic field during a small portion of these periods. Australia is fortunate in having glacial varves of very much greater age, notably in the Proterozoic and Carboniferous. Work has begun with an investigation of the stability and a determination of the average direction of the magnetization of varves in the Kuttung Series in the Hunter Valley.

The Upper Kuttung Series is of Upper Carboniferous age and consists of volcanics, glacial and peri-glacial deposits[2]. Results from the volcanics are being reported elsewhere[3]. The varves are for the most part grey or buff in colour, their intensities of magnetization are low ($3–10 \times 10^{-6}$ e.m.u., c.g.s. per c.c.) and their directions unstable; the varves at the type locality of Seaham exhibit such characteristics. But occasionally thin bands of pink or red colour occur,

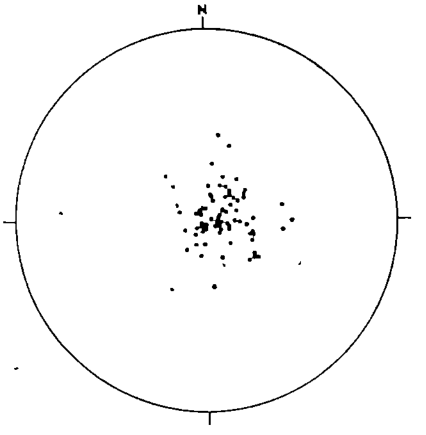

Fig. 1. Directions of magnetization in varve specimens.
The directions are plotted on the lower hemisphere of a stereographic polar projection. This projection is also used in the other figures. Dots signify north-seeking poles (sites *A*, *B* and *D*) and circles south-seeking poles (site *C*). Correction is made for geological tilt, so that the plane of the projection is the bedding plane, which is assumed to have been horizontal at the time of deposition

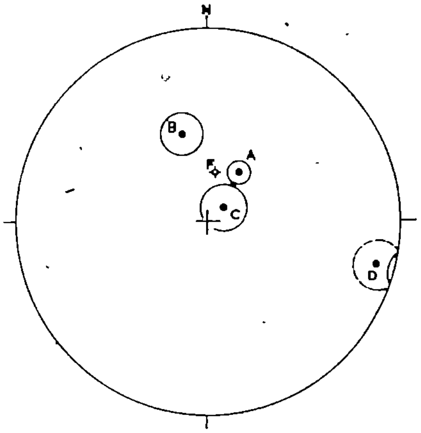

Fig. 2. Mean directions at four localities uncorrected for tilt of the beds.
The plane of the projection is the present horizontal, so that the directions are as they are in the field. Plotting is on both upper (circles) and lower (dots) hemispheres. *F* is the direction of the present Earth's field

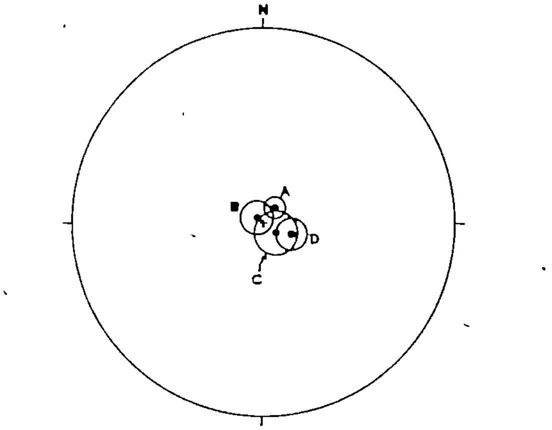

Fig. 3. Mean directions at four localities after correction for tilt. The plane of the projection is the bedding plane and plotting is on the lower hemisphere

and these have been sampled at four localities (designated *A*, *B*, *C* and *D*) in the lower Hunter Valley, seventy-five samples being taken in all. The intensities of magnetization are higher (10–50 × 10^{-6}) and the directions, which are more or less perpendicular to the bedding (Fig. 1), are stable. This has been shown by using Graham's fold test[4] as follows: the directions at the four sites are scattered when the beds are *in situ* (Fig. 2) but are grouped together after correction for geological tilt is made (Fig. 3). Thus, these directions of magnetization were imposed prior to the folding which occurred in Permian times, and may be identified with the directions of the Earth's magnetic field in this region during the Upper Carboniferous. At site *C* the north-seeking directions of magnetization are directed towards the upper bedding surface, whereas at the other three sites they point downwards in the sequence. According to current terminology these are designated normal and reversed, respectively.

It may be supposed that, when the secular variation is averaged out, the geomagnetic field approximates to a geocentric dipole. Assuming this average has been achieved, the poles of this dipole axis may be calculated and are given in Table 1 and plotted in Fig. 4. These poles are between 80° and 90° distant from determinations from the Mississippian[5] and Pennsylvanian[6] of the United States, and from the Lower-Carboniferous of Britain[7]. Although comparatively small statistical differences may separate the Carboniferous poles of Britain and the United States, it seems very probable that for these regions at this time the pole lay in what is nowadays the South Atlantic with the anti-pole in eastern Asia, and the geomagnetic field over these regions was substantially dipolar. The complete disagreement of the Kuttung poles suggests either that Australia has moved relative to Britain and the United States, or that the geomagnetic field, although approximately dipolar over a large part of the northern hemisphere, was not so in the southern hemisphere.

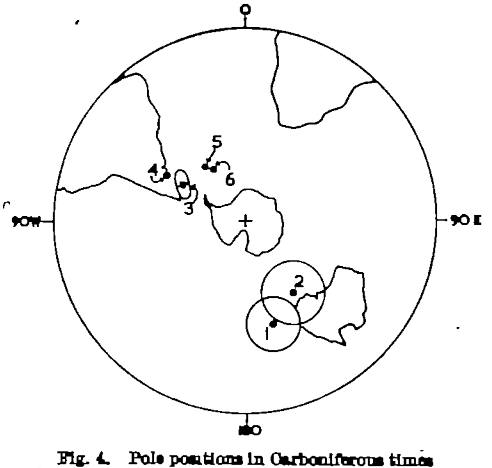

Fig. 4. Pole positions in Carboniferous times
The poles are numbered as follows: 1 and 2, Kuttung varves and lavas of Australia; 3 and 4, Naco sandstones (Pennsylvanian) and Barnett shales (Mississippian) of the United States; 5 and 6, Lower Carboniferous sediments and lavas of Britain

Table 1. Mean direction of magnetization is specified by its declination *D* measured east of geographical north, and inclination *I* positive downwards. α is the Fisher (ref. 8) angle of confidence at $P = 0{\cdot}95$. Because of reversals, the sign of this direction is uncertain. The pole errors δp and δm in the direction of, and perpendicular to, the co-latitude are at $P = 0{\cdot}95$

Mean direction of magnetization			Sampling area		Pole positions			
D	*I*	α	Lat.	Long.	Lat.	Long.	δp	δm
90°	+ 84°	6	33° S	151° E.	165° E.	32° S	12	12
270°	− 84°				15° W.	32° N.		

The preceding argument does not assume any correlation of the magnetic and rotational axes of the Earth, but in order to make comparisons between the palæoclimatic and palæomagnetic data, let it be supposed that when averaged over several thousands of years the geocentric dipole has always been directed along the axis of spin. This may be referred to as the geocentric axial dipole hypothesis. The geographical latitudes of eastern Australia and western Europe now become approximately 80° and 70°, respectively. Since the pioneer work of Sir Edgeworth David, the climatic conditions under which the Upper Kuttung Series were laid down have always been regarded as cold or glacial—conditions which are most likely to have been attained in high latitudes. Western Europe, on the other hand, provides no evidence of glaciation, and geological opinion favours warm and wet conditions at this time. The agreement between the palæoclimatic and palæomagnetic evidence at the same place is consistent with the geocentric axial dipole hypothesis. On the other hand, the contrast between these two lines of evidence when antipodal regions are considered suggests that either western Europe and eastern Australia have moved relative to each other since the Carboniferous, or that this hypothesis is false.

I wish to thank Dr. W. R. Browne, of Edgecliff, Sydney, who was my instructor and guide during field-work, and the head of this Department, Prof. J. C. Jaeger, for his help in discussion.

Nitrogen Fixation by a Species of *Pullularia*

During the past few years an increasing number of organisms, other than *Azotobacter* and *Clostridium* species, have been found to fix small quantities of atmospheric nitrogen. *Chromatium* sp.[1], *Aerobacter aerogenes*[2], *Methanobacterium omelianskii*[3], *Pseudomonas*-like soil bacteria[4] and soil yeasts (*Saccharomyces* and *Rhodotorula* species[5]) have all been reported in the past three years as fixing atmospheric nitrogen. Nitrogen fixation by various lichens has also been described[6].

In the course of investigations by one of us (M.E.B.) concerning the stimulation of nitrogen-fixing organisms in the rhizosphere of clover plants grown in a clay–loam soil (pH 6·8) a black yeast-like organism regularly appeared on nitrogen-deficient agar plates. It has been identified as a species of *Pullularia*. On transfer to 10-ml. quantities of glucose–phosphate liquid medium containing no source of combined nitrogen the *Pullularia* grew well. After 14 days, nitrogen content assessments were made on replicate cultures by the micro-Kjeldahl method; compared with controls, gains of nitrogen of 0·20–0·26 mgm. per culture were found, corresponding to a fixation rate of 4–5 mgm. of atmospheric nitrogen per gm. of glucose supplied.

An estimation of the numbers of *Pullularia* in the clay–loam soil gave an approximate count of 8×10^3 cells per gm. of soil. The fungus was no more abundant in the rhizosphere of clover plants than in the surrounding soil.

Independently, Metcalfe has isolated what appears to be the same fungus from chalk soil, heath soil and a woodland mull soil and also from the thallus of the lichen *Cladonia uncialis*. These isolates grew readily in nitrogen-deficient washed agar media and in liquid media without added nitrogen compounds.

Grown on nitrogen-rich media, the fungus very rapidly loses its ability to fix atmospheric nitrogen. On nitrogen-deficient agar media, most of the growth is within the agar as rhizoid-like outgrowths from a small surface colony. Dark brown or black pigmentation occurs after a few days growth. On malt or yeast agar, pigmentation is usually slight.

We are indebted to Dr. Beryl L. Brady for identification of the organism as *Pullularia* sp.

Origin of Antibiotic-Resistant Staphylococci

It is probable that antibiotic-resistant variants of bacteria arise by spontaneous mutation, and their further spread depends upon selective factors in the environment. Thus an antibiotic-resistant variant has a greater chance of survival when growing in the presence of the antibiotic, and this would explain the increase in the number of penicillin-resistant strains of *Staphylococcus pyogenes* isolated from hospital patients that has occurred since the introduction of the antibiotic[1].

However, a peculiar and significant finding is that the proportion of penicillin-resistant staphylococci in hospitals is increasing not only among those isolated from patients treated with penicillin, but also among those found in the noses of healthy carriers among the medical and nursing staff, most of whom have not been treated with the antibiotic. Thus, more than 90 per cent of the nasal carriers in a hospital may harbour penicillin-resistant *Staph. pyogenes*[2] and new personnel entering hospital with carrier strains which are penicillin-sensitive are, for the most part, rapidly colonized by the penicillin-resistant forms[3]. It has been suggested that these penicillin-resistant strains are acquired from the patients by contact and cross-infection, but it is unlikely that the penicillin-resistant strains are more suited to colonization of the healthy nose than the penicillin-sensitive strains, for, if this were so, one would expect their spread among the general non-hospital population. Our observations over the past few years show no evidence that there is a significant increase in the proportion of penicillin-resistant staphylococci among the general population.

A possible explanation is that the nurses and medical staff receive enough antibiotic on their hands and fingers and from the air to maintain a selective concentration in their noses which inhibits the penicillin-sensitive staphylococci. Confirmation of this possibility was sought by investigating the incidence of resistant strains in healthy carriers in an environment contaminated with antibiotic but which lacked treated patients as a source of resistant strains. Such an environment was a factory which handles and dispenses penicillin.

The staff of this factory, and a group of individuals from a general practice in the same geographical locality who had no contact whatsoever with the factory or its personnel, were first examined for nasal carriage of *Staph. pyogenes*. The carrier-rates for these groups and the antibiotic sensitivity and bacteriophage type of the carrier strains of *Staph. pyogenes* are shown in Table 1.

The carrier strains in the factory personnel resemble those commonly found in hospitals both in their resistance to penicillin (due to penicillinase production) and the limited number of types present. The majority of strains were of group III types and quite distinct from those isolated from the carriers among the general population group, which, in turn, are typical of the strains found elsewhere in the non-hospital population.

The penicillin content of the air was measured next, using an impinger-sampler collecting on to agar plates. The results are shown in the last column of Table 1. The concentration of penicillin present in the air of the penicillin filling-room and packing-room appears to be sufficient to depress the growth

Table 1. NASAL CARRIERS OF *Staph. pyogenes* INSIDE AND OUTSIDE THE PENICILLIN FACTORY. CHARACTERISTICS OF THE CARRIER STRAINS AND CONCENTRATION OF PENICILLIN IN THE AIR OF THE FACTORY

Group	No. of persons examined	Average No. of organisms on nose swab	Carriers of *Staph. pyogenes* (per cent)	Percentage carrier strains				Approximate recovery of penicillin per cu. ft. of air
				Penicillin-resistant	Phage group I	II	III	
Penicillin filling-room and packing-room	38	+	8	100	33	0	66	Filling-room 0·1–0·5 μgm. penicillin Packing-room 0·02–0·1 μgm.
General (no penicillin) packing-room	32	+++	27	100	36	0	60	Traces of penicillin. Amounts of other inhibitory material present
Administrative	28	+++	32	100	30	0	70	0
General population outside factory	36	+++	30	12	30	62	8	—

of all species in the nares of persons working in that environment, and the strains of staphylococci isolated were all penicillinase-producers. Much smaller amounts of the antibiotic were recovered from the air of other parts of the factory, which, though not sufficient to depress the growth of nasal flora, is sufficient to select and maintain penicillin-resistant *Staph. pyogenes*. Although no penicillin could be detected in the air of the administrative block, it is probable that traces of the antibiotic reach this site by air and dust, and on the clothing and fingers of the staff; thus it could be transferred to their nares and be effective in maintaining strains of penicillin-resistant staphylococci.

The evidence from these experiments confirms that penicillin in the environment is an important factor in selecting and maintaining penicillin-resistant strains of *Staph. pyogenes*. It is reasonable to compare the occurrence and distribution of these strains in this factory and a typical general hospital, and to suggest that antibiotic in the environment is the important factor in hospital which leads to widespread colonization of personnel with antibiotic-resistant strains of *Staph. pyogenes*. Investigations are in progress to try to demonstrate antibiotic in hospital air.

Heleococcum aurantiacum: an Uncommon Weed Fungus of Mushroom Compost

MUSHROOM compost, if correctly prepared, is a selective medium for the mycelium of the cultivated mushroom. Under commercial conditions, however, various adverse factors may give rise to the production of a medium encouraging the growth of other fungus 'weeds', invasion by which may cause greater or lesser competition to the developing mushroom spawn. Some of these fungus invaders, such as *Oedocephalum* sp., *Papulaspora byssina* and *Coprinus* sp., are common; others, such as *Sporendonema purpurascens* and *Pseudobalsamia microspora*, occur sporadically; one or two are extremely rare, and of these latter the fungus *Heleococcum aurantiacum* has only occurred twice in samples examined in these laboratories.

In 1935, a compost sample was forwarded for examination. It was full of fine mycelial threads producing globular perithecia which contained numerous asci with eight ascospores in each. The curious thing was that the ascospores, as they ripened, became two-celled so that the ascocarps were obviously not those of the usually occurring Ascomycetes in compost. Specimens were forwarded to the Plant Pathology Laboratory to the late Dr. George Pethybridge for examination. In correspondence, he stated, "Your fungus is a puzzle and a very intriguing one. It has been shown to Mr. Ramsbottom of the British Museum, but he is unfamiliar with it". Later, Dr. Pethybridge wrote, "we have now succeeded in identifying your Ascomycete, at any rate as far as the genus is concerned. C. A. Jørgensen[1] . . . published (in English) an account of a new fungus which he called *Heleococcum aurantiacum* n.gen. n.spec. Mr. Ramsbottom came across it by accident not long ago and called our attention to it. . . . It is rather curious that although this paper was published twelve years ago, the new genus is not to be found mentioned in Saccardo or in Clements and Shear. In fact, it does not seem to have been gathered up into any published list so far as we can ascertain". Jørgensen's description is accompanied by excellent illustrations.

It was found in this laboratory that *H. aurantiacum* grew well on oatmeal agar and produced perithecia, and cultures were forwarded to the Centraalbureau voor Schimmelcultures.

Since 1935 there seems to be no further record of *Heleococcum aurantiacum*, and compost samples examined here have shown no signs of this fungus. This may be due, so far as mushroom compost is concerned, to improved methods of preparation and pasteurization, causing almost complete elimination of the more fragile weed fungi present. It was somewhat surprising, therefore, to find *Heleococcum aurantiacum* once more in compost samples in February of this year, after a lapse of twenty-two years.

Relationship between Shoot Apex and Effect of Gibberellic Acid on Elongation of Pea Stems

Brian and Hemming[1] have recently shown that gibberellic acid is relatively inactive in inducing the elongation of internode segments of dwarf pea. They have found, however, that in the presence of indolylacetic acid, gibberellic acid induces a more marked increase in the extension of the internode segments.

It is of interest to note from previous accounts[2] that gibberellic acid induces much more marked increases in the elongation of stems of intact green plants than it does in stimulating the cellular extension of isolated plant parts (that is, wheat coleoptiles, pea internode sections, etc.). This is in striking contrast to the classical auxins, such as indolylacetic acid, which are much more easily detected in bioassays with isolated segments grown in the dark.

With these interesting and unexplained differences before us, we have looked into the effect of gibberellic acid on the elongation of stems of Alaska pea seedlings from which vital (from a physiological point of view) portions of the anatomy of the plant had been severed. The seedlings used in these experiments were grown in the dark until they were six days old. Ten uniform seedlings were then decapitated, for each replicate, by cutting through the first node with a sharp razor, or de-rooted, or left intact. The seedlings were then immersed in either aqueous solutions containing 10 p.p.m. gibberellic acid or in distilled water. One set of seedlings was placed under red fluorescent lights, while the other set was kept in total darkness. After two days, the total height of the seedlings was recorded. The results are reproduced in Table 1.

Table 1. EFFECT OF GIBBERELLIC ACID ON ELONGATION OF ETIOLATED PEA SEEDLINGS WITH DIFFERENT TISSUES REMOVED PRIOR TO TREATMENT IN LIGHT AND DARK

Tissues removed from seedlings	Total increments of growth (in cm.) for ten seedlings held in Red light		Darkness	
	G.A. (10 p.p.m.)	Water	G.A. (10 p.p.m.)	Water
Shoot apices	2·4	2·7	4·6	2·0
Roots only	96·6	45·6	107·3	82·6
Roots and apices	5·3	2·1	3·7	2·9
None (Ck.)	93·2	50·4	106·0	87·3

Required for statistical significance: differences of 8·6 at 5 per cent level; differences of 9·7 at 1 per cent level.

Intact seedlings responded to gibberellic acid more markedly in red light than the dark, confirming the recent work of Lockhart[3]. Decapitated seedlings made little growth either in the presence of gibberellic acid or in its absence, regardless of whether they were grown in red light or in the dark. De-rooted seedlings with shoot apices responded to gibberellic acid much more markedly in red light than in the dark, acting similarly in this respect to intact seedlings. However, de-rooted seedlings, without shoot apices, which are, in effect, second internode segments, did not respond to gibberellic acid either in red light or in darkness, resembling decapitated seedlings with an intact root system.

The results of these experiments indicate that the shoot apex is necessary for maximum elongation of the second internode of Alaska peas and that gibberellic acid will not replace the stimulus for cellular extension that is probably derived from the apex.

In view of the report by Brian and Hemming[1] on a possible interdependence between indolylacetic acid and gibberellic acid, coupled with the results described here, there is some indication that there may be a close relationship between growth factors synthesized and translocated from the apex, and the exogenously applied gibberellic acid. One may speculate that this relationship is possibly a type of 'sparing action' by which exogenously applied gibberellic acid 'protects' against the inactivation of endogenous growth hormones, particularly where the inactivation mechanism is mediated by light. These and other questions will be discussed more fully in forthcoming publications in the Contributions from the Boyce Thompson Institute.

Unisexual Flowers in the Ericales

THE flowers of the Epacridaceae have been described as hermaphrodite[1,2] or hermaphrodite, rarely dioecious[3], but in the latter case no examples of dioecy are quoted. The following notes concerning species previously described as hermaphrodite indicate that unisexual flowers may be not uncommon in this family.

In November 1954 I noted that a lone plant of *Cyathodes colensoi* in the Christchurch Botanic Gardens flowered profusely but set no fruit. A year later a large population was examined at Lake Lyndon, Canterbury, and two types of plant were found which were obviously male and female. Five plants were labelled in the field, and only the two classified as female set fruit. Transplants from this population set no fruit in isolation, but did so with the appropriate hand pollination. The tiny stamens in the female may dehisce but contain no pollen (Fig. 1) and the flower illustrated by Cheeseman[4] is of this type. Female flowers are smaller than males. Although pollination has not been observed, the flower structure suggests that insects are the main agent, for the stigma is inside the petal tube, the opening of which is only $\frac{1}{8}$–$\frac{1}{4}$ mm. across and surrounded by hairs.

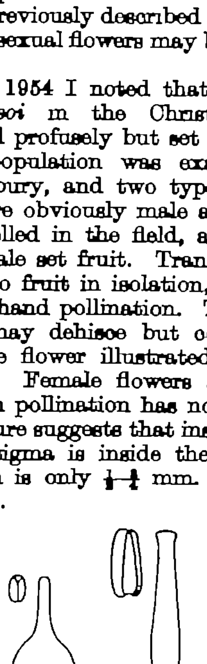

Fig. 1. Upper: *C. colensoi*, Lake Lyndon. Female, left; male, right. Lower: *C. acerosa*, Kaiteriteri. Female, left; non-fruiting hermaphrodite, right

In February 1956 at Kaiteriteri, Nelson, it was noted that some plants of *Cyathodes acerosa* were fruiting and others were not. Several plants of each type were marked, and the flowers were examined in the following October. The plants which had borne fruit were definitely female. The anthers were larger than those of female *C. colensoi*, but again were empty (Fig. 1). Cheeseman's illustration[4] is referable to this type. But those plants without fruit bore flowers which were hermaphrodite in structure, with good pollen and with ovules. The fruiting was rechecked in 1957 and the same result obtained as in the previous season. Similar types of flower were found near Springfield, Canterbury, and here again, in two seasons, marked female plants set fruit, but apparently hermaphrodite plants did not. In contrast, Mr. W. B. Brockie, of the Otari Gardens, Wellington, has a lone plant collected from Raetihi, North Island, which has hermaphrodite flowers, and which fruits abundantly each year. No macroscopic differences have been noted between flowers from this plant and the non-fruiting plants of the Kaiteriteri and Springfield populations. But the fruits from Otari are white whereas the others are red. The cause of the sterility of the apparently hermaphrodite plants will be investigated. Lack of either self- or cross-pollination may be ruled out. The anthers are on a level with the stigma and self-pollination is inevitable. Cross-pollination must also occur readily as shown by the fruiting females, and this will be easier than in *C. colensoi*, as the anthers and stigma are well exposed.

A population of *Leucopogon fasciculatus* near Springfield was also found to contain fruiting female plants and non-fruiting plants with apparently hermaphrodite flowers.

Hooker[5] noted that *C. colensoi* was closely allied to *C. tameiameiae* and to *Leucopogon suaveolens*. By the courtesy of Dr. W. B. Turrill, specimens of these at Kew were kindly examined for me by Dr. R. Melville. A specimen of *L. suaveolens* (A. E. Pratt, New Guinea, 1908) had normally dehisced anthers, young fruit and appeared hermaphrodite. Another sheet (Loher, 3784, Philippines) bore what were apparently male and female specimens. The males had large normally dehisced anthers and no developing fruit; the females had small, unopened anthers and young fruit. Specimens of *C. tameiameiae* were apparently either male with large normally dehisced anthers, or female with smaller anthers containing no pollen. Dr. Melville has pointed out to me that Skottsberg[6] had earlier suggested that dimorphous flowers occurred in this species (which he referred to *Styphelia*) and also in *C. douglasii*, but had considered gynodioecy probable.

The flowers of the Ericaceae have been described as hermaphrodite[1–3], but an exception is *Epigaea*, which is variously described as dioecious[7] or androdioecious or gynodioecious[1]. An early suggestion[8] that *Gaultheria antipoda* and *G. rupestris* of New Zealand are gynodioecious has been overlooked. Mr. H. Talbot has recently and independently noted that unisexual flowers occur in some New Zealand species of *Gaultheria* and *Pernettya* and these are being investigated to determine whether they are dioecious or gynodioecious. Thomson's record for *G. antipoda* has not been substantiated.

During this work a request was made to the University of Tasmania for further material of *Cyathodes*, and it was found that Dr. C. V. Rao, Colombo Plan Research Fellow, had independently found unisexual flowers in several genera of the Epacridaceae.

Nature of the Bactericidal Agent in Sea Water

Earlier work by myself in co-operation with Miss R. E. Martin upon the toxicity of sea water towards *Escherichia coli* demonstrated the presence, in the coastal waters of New Zealand, of the bactericidal agent which has been observed by other workers and been the subject of a recent review by Greenberg[1]. We also found that this organism will survive and actively multiply in sea water containing a very small addition of lactose broth. Assuming that some constituent of the lactose broth was able to antagonize the toxic effect of the sea water, well-washed cultures of *E. coli* were suspended in mixtures of sea water and the individual constituents of lactose broth. The meat extract ('Lab lemco') was found to contain the protective agent. Yeast extract behaved similarly.

Following Miss Martin's departure overseas, I continued this lead by examining a wide range of pure substances likely to occur in meat or yeast extract, that is, amino-acids, vitamins, purine and pyrimidine bases, etc. Of the substances tested, cysteine gave protection to the bacteria at very low concentration, as shown in Table 1.

Table 1. Effect of Cysteine upon Survival Numbers of *E. coli* (*N.T.C.* 8796) in Filtered Sea Water

Cysteine added (μgm./litre)	No. of survivors after 18 hr. at 37° C.
0	1
3·5	5
35·0	180,000
350	180,000

That such an effect should be obtained from a sulphur-containing compound is interesting, as Harvey[2] states that cystine plus sodium sulphide or thiourea alone increased the growth of *Skeletonema costatum* in sea water media. Matudaira[3] obtained similar results by addition of sodium sulphide to sea water media.

These observations suggested that the toxic agent in sea water was in some way involved in sulphur metabolism or else interfered with the sulphydryl groups of essential enzymes. Some antibiotics are known to act by such a mechanism, but the universal distribution of the toxic agent throughout the oceans of the world did not suggest an organic substance of biological origin, but rather some substance of an inorganic character.

A consideration of the chemistry of sea water and a search of the literature revealed that Winkler[4] had demonstrated that a considerable portion of the iodine naturally present in sea water was there as iodate, the remainder being iodide. In view of the known reactivity of halates and sulphydryl compounds at neutral pH values, this presence of iodate in sea water could explain the toxicity towards the coliform bacteria and their protection by cysteine.

The presence of iodate in the local coastal waters of Wellington, New Zealand, has been established by me. The method used was to acidify the sample, add potassium iodide solution, and then estimate the tri-iodide ion spectrophotometrically at 355 mμ. Sulphamic acid was used for acidification as it effectively eliminated nitrite interference. The amount found ranged from nil on polluted beaches to 0·034 p.p.m. iodate, which has an oxidizing power equal to 0·15 p.p.m. free iodine.

This postulation of iodate as the toxic substance in sea water is in agreement with (*a*) the universal distribution of the toxic agent throughout the oceans; (*b*) variable degree of destruction by autoclaving: the iodate reacting with organic matter, the degree of destruction is dependent upon the nature and quantity of organic matter present; (*c*) protection of the bacteria by cysteine.

Vacarro and his fellow workers claim to have destroyed the toxic agent by chlorination[5]. However, these workers removed the excess chlorine with thiosulphate, and it was possibly this latter substance reacting with iodate that gave increased survival of the test organism.

These investigations are proceeding.

Separation and Identification of Aromatic Acids in Plant Tissues by Paper Chromatography

In the course of studies on the aromatic constituents of *Theobroma cacao* L., a method has been developed for the separation by one- and two-dimensional paper chromatography of the naturally occurring substituted cinnamic acids, which is also applicable to many other aromatic acids of plant tissue.

A separation of the common phenolic acids of plants has been reported by Bate-Smith[1], who employed a toluene solvent system and the Forestal solvent system. Both of these methods suffer, however, from the disadvantage that the substituted cinnamic acids, which are of very wide distribution[2], tend to lie very close together on the chromatogram, possessing R_F values within the range 0·78–0·86 in the Forestal solvent and 0·05–0·25 in the toluene solvent. Furthermore it has been observed that, in the plant material under investigation, several spots revealed by these uni-dimensional methods could be resolved by two-dimensional chromatography into two or more components. Similar difficulties are attendant upon the use of *m*-cresol/acetic acid/water and butanol/acetic acid/water for the separation of these compounds[3].

Table 1. R_F Values in Benzene / Acetic Acid / Water

	R_F values	Ultra-violet fluorescence	Colour with diazotized *p*-nitraniline
Substituted cinnamic acids:			
Chlorogenic acid	0	blue	brown
Caffeic acid	0·04	blue	red-brown
p-Coumaric acid	0·49	faint deep blue	orange
o-Coumaric acid	0·64	silver blue	yellow → red
Ferulic acid	0·90	blue	red
Dimethoxy cinnamic acid	0·99	blue	none
Miscellaneous hydroxy-aromatic acids:			
Ellagic acid	0	none	brown
Protocatechuic acid	0·07	none	brown → purple
Salicylic acid	0·98	deep blue	yellow
Gallic acid	0	none	brown

Of a large range of solvent combinations investigated in this laboratory, the best results were obtained with a benzene/acetic acid/water system (60 : 70 : 30), the substituted cinnamic acids showing a wide range of R_F values, and giving rise to spots of a small and well-defined character. This solvent system is, however, extremely sensitive to changes of temperature, and the water dissolved in the hydrocarbon phase may be expelled if such changes occur. It is therefore essential that the temperature be kept constant throughout the procedure. Care should accordingly be taken to ensure that the solvents and the vessel in which they are mixed are at the same temperature as the tank. After mixing, the solvent system is allowed to stand at this temperature for one hour, when the lower aqueous phase is removed. The hydrocarbon phase is allowed to remain in the separating funnel for a further 15 min., when any water expelled from the hydrocarbon phase is removed. At the end of this period, the hydrocarbon phase is transferred to the trough of a tank, which has been equilibrated with the aqueous phase for 24 hr. previously. The solvent system may be further stabilized by carrying out the procedure at a reduced temperature, the R_F values listed in Table 1 being obtained by ascending development of the chromatogram (Whatman No. 1 filter paper) in a constant-temperature room maintained at 15° C. In our current experiments the identity of the isolated compounds is confirmed by running them against reference compounds.

A development period of 3–4 hr., during which the solvent front advances about 25 cm., was found to give a good separation. In the case of complex mixtures of aromatic acids, it was found to be advantageous to submit the chromatogram to further development with a second solvent system. Although the previously reported solvent systems have not lent themselves to two-dimensional separations by reason of the somewhat diffuse character of the spots obtained in the primary development, the adoption of the benzene solvent as the primary solvent system, and the consequent improvement in the definition of the resulting spots, makes further development with a second solvent system wholly practicable. For this purpose acetic acid / hydrochloric acid / water (100 : 10 : 30) was found to be very satisfactory[1].

For the detection and identification of these compounds on the chromatogram, their properties of fluorescing in ultra-violet light and of forming coloured derivatives on spraying with 1 per cent alcoholic ferric chloride or diazotized *p*-nitraniline[4] were utilized. The colours recorded in Table 1 were those produced immediately on spraying. In certain cases the colours first formed underwent further change on standing. These changes provided a further criterion for the identification of substances of similar R_F values.

Ascorbic Acid Content of Baobab Fruit

THE Hausa-speaking farmers and Fulani cattle owners who live in the savannah regions of Northern Nigeria make free use of the leaves and fruit of the baobab tree (*Adansonia digitata* Linn.). The leaves, either fresh or dried and pulverized, are used in the soup which is poured over the dish of porridge made from guineacorn (sorghum) or millet (pennisetum and eleusine) flour. During the season while the fruit of the tree is ripe, from February to April depending on the latitude, the pulp is removed from the fibres and seeds by kneading in cold water and then passing the emulsion through a sieve. The resulting white or whitish-yellow fluid (Hausa—*gubdi*) is used by the farmers to dilute the thick guineacorn dough (*fura*) to a thin gruel (*kunu*), which is the traditional morning or midday meal. The cattle-owning Fulani use the emulsion to adulterate milk. This milk and baobab fruit juice mixture is a popular drink with the Hausa farmer, and is available, if he has money to buy it, at a hot time of the year when new farms are being cleared, or hoeing of old farms is taking place, preparatory to sowing. The kernels of the seeds are used to make into a cake for flavouring soup.

Dalziel[1] says that the pulp of the baobab fruit "apparently contains free tartaric acid, potassium acid tartarate, with pectin, glucose and mucilaginous matter". Carr[2] has concluded, from the results of analyses using both the dichlorophenolindophenol and dinitrophenylhydrazine methods to estimate ascorbic acid, dehydroascorbic acid and diketogulonic acid, that the pulp contains large quantities of ascorbic acid; that this is present mainly in the reduced form, and that no appreciable amounts of substances which interfere with the dichlorophenolindophenol method of assay are present. The diets of the Hausa-speaking peoples throughout the rest of the year provide them with only small amounts of ascorbic acid, and it was considered to be of importance to determine whether Nigerian baobab fruit also contains good quantities of the vitamin.

The Hausa-speaking natives of Bunga-Ningi, in Bauchi province (11° N., 9·30° E.), were observed to consume quite large quantities of baobab fruit juice either in sour milk or in their morning gruel, the juice being stirred into the flour after it has been cooked. One of the farmers was asked to bring six fruits at the correct stage of ripeness for making the juice. The average composition of the fruits found is given in Table 1.

Table 1

	Mean weight (gm.)	Range (gm.)
Whole fruit	462	554–341
Capsule	203	249–156
Seeds and fibres (dry)	165	210–114
Ratio of pulp to weight of fruit	0·21	0·22–0·19

The dry pulp was scraped from the seeds, ground to a fine powder, and the moisture content estimated in a Carter–Simon oven, the average of three estimations on each of the six pulps being 20·8 per cent (range 18·1–23·1). The ascorbic acid content of the dry pulp was estimated by the 2 : 6-dichlorophenolindophenol method[3], the average of three estimations on each of the six samples being 373 mgm./100 gm., (range 302–445 mgm./100 gm.). These are higher figures than those given by Carr for Rhodesian baobab fruit.

It was found that an average-sized baobab fruit made about one litre of juice, using native methods of preparation, and that the ascorbic acid concentration in it was 75 mgm./100 gm. (range 54–106). It is apparent that a destruction of ascorbic acid takes place during the preparation of the juice.

The consumption of baobab fruit juice by the Hausa-speaking people of Bunga-Ningi was measured over a period of a week in late February 1957 and was found to vary from 130 gm. (adult males) to 27 gm. (children 4–6 years of age). Using the figures given above this would provide 98 mgm. and 20 mgm. of ascorbic acid. At other times of the year the intakes of ascorbic acid had been found to be 17 mgm. and 16 mgm. respectively. The length of the baobab fruit season is estimated by the population of Bunga to be about two months, and it is therefore an important source of ascorbic acid in the local diets.

Nucleic Acid Derivatives in Soils

DURING investigations into the nature of soil organic phosphates, purine and pyrimidine bases have been identified in preparations from three representative mineral soils from north-eastern Scotland. They were found mainly in the humic acid fractions of the organic matter, that is, that portion of the organic matter which is precipitated when an alkaline soil extract is acidified, and were clearly not in the free state, but were released by perchloric acid hydrolysis. Afterwards they were separated from the bulk of the hydrolysate by adsorption on a cation exchange column (*IR*-120), from which they were eluted with 5 *N* hydrochloric acid and identified by paper partition chromatography with solvents butanol/ammonium hydroxide[1], and *iso*propanol/hydrochloric acid/water[2]. The bases so far identified are guanine, adenine, cytosine and thymine, which appear to be present in similar amounts, and smaller quantities of uracil. There is organic phosphate present in the humic acid fractions, equivalent to about 10 per cent of the total soil organic phosphate, and the evidence suggests that part of this may be accounted for as deoxyribonucleic acid. The conditions under which the soils were extracted would cause considerable hydrolysis of ribonucleic acid to mononucleotides, which would not appear in humic acid precipitates, so that the small quantity of uracil relative to thymine in the precipitates cannot be taken as an indication of the relative amounts of ribonucleic acid and deoxyribonucleic acid in the original soils. The quantities found are in excess of the total amounts likely to be present in soil micro-organisms.

The presence in soils of substances having some of the properties of nucleic acids has been reported before[3], but more recent attempts[4] to confirm their presence proved inconclusive although there was some evidence that minute amounts of soil phosphates were in this form. Only ribonucleic acid or its derivatives were considered, however, and attention was confined mainly to the fulvic acid fractions of soils.

The presence of thymine in the hydrolysate of soils or soil products does not appear to have been reported previously, nor have the four bases of either type of nucleic acid been isolated from one product.

This investigation will be reported fully elsewhere.

Isolation of Uranediol from the Urine of Pregnant Mares

THE isolation of uranediol from the urine of pregnant mares has been described by Marker and his colleagues[1] and by Klyne[2]; isolation has also been effected by Bauld and Heard[3]. Since the reported isolations of uranediol have been few, and since uranediol appears to be the first D-homosteroid of natural origin to be isolated[4,5], we believe that it is of interest to record that we have isolated uranediol in small quantity from pregnant mares' urine collected throughout the second half of the term of pregnancy.

Urine was collected continuously in batches from a large number of mares during approximately the seventh, eighth, ninth and tenth months of pregnancy and each batch of fresh urine was processed by solvent extraction to a separate concentrate. A portion of each of the resulting concentrates, equivalent to 1 per cent of the total weight, was withdrawn and these samples pooled and hydrolysed, and a non-ketonic, non-phenolic fraction isolated. This non-ketonic, non-phenolic fraction was acetylated and on chromatography yielded an acetylated compound (approximately 300 mgm. per 100 gal. of urine processed) which melted sharply at 159–160°. The physical properties of this compound (melting point 159–160°, $[\alpha]_D^{23}$ − 28·4° (chloroform)) and the analysis (C, 74·5, 74·4; H, 10·1, 9·9 per cent) agree with the values previously reported[1,2] for uranediol diacetate. The infra-red spectrum of our compound in the finger-print region (in carbon disulphide) was measured by Dr. I. D. P. Wootton (Postgraduate Medical School, London) and was found to be identical with that of an authentic sample of uranediol diacetate supplied by Dr. W. Klyne.

Production of Rat Serum Proteins in Irradiated Mice

IN the course of a study on the protection of mice against a lethal dose of X-rays, it was found in this laboratory that the administration of homologous or heterologous (rat) bone marrow after the irradiation may result in a significant reduction of mortality. In the animals surviving after heterologous therapy the circulating erythrocytes were agglutinated by anti-rat serum; furthermore, the granulocytes showed an alkaline phosphatase reaction which is specific for rat white cells. These results proved that a transplantation of rat hæmatopoietic tissue had been achieved[1].

Since it is known that certain serum proteins are synthesized by cellular elements of the bone marrow, a serological typing of the serum proteins of these mice seemed of interest. Results from investigations by Makinodan[2] suggested a failure of the transplantation of rat plasmacytopoietic cells, since rat serum protein could not be detected in the circulation of lethally irradiated mice after treatment with rat bone marrow.

Precipitating anti-rat serum was produced by immunizing chickens with alum-precipitated rat serum. In testing the sera, the capillary precipitation reaction (ring reaction) was used. Sera were obtained which, after absorption with normal mouse serum, precipitated rat serum specifically with a titre of 1 : 80,000.

The sera of *CBA* mice were tested about 100 days after the irradiation and the treatment with rat (*WAG* strain) bone-marrow cells.

So far, 15 sera have been tested. A positive reaction was obtained in all cases indicating the presence of rat serum proteins in these mice. Two-fold serial dilutions of the antigen yielded titres ranging from 1 : 256 to 1 : 2,048 with the antiserum employed. These titres were not influenced by a previous absorption of the chicken anti-rat serum with intact and hæmolysed rat erythrocytes, indicating the specificity of the reaction for rat serum proteins. This result, together with the agglutination and alkaline phosphatase reactions, suggests that transplantation of rat hæmatopoietic tissue was complete. In preliminary experiments applying micro-immuno-electrophoresis to these sera according to the method of Scheidegger[3], precipitation by anti-rat serum of a component travelling with the speed of normal rat gamma globulin was observed.

Role of Organ-Specific Antigen during 4-Dimethylaminoazobenzene Carcinogenesis in the Rat Liver

In recent years, attention has been focused upon the immunological concept of the etiology of carcinogenesis. Burnet[1] has developed the thesis that the control of cell multiplication may in part be mediated by 'self-marker' antigens present in all expendable cells, and he has pointed to the work of Weiler[2] as strong support for Green's[3] immunological hypothesis of carcinogenesis. By use of the fluorescent-antibody technique of Coons and Kaplan[4], Weiler provided evidence to support his earlier observations[5] that the organ-specific antigen is absent from tumour cells. While frank tumour cells failed to fluoresce in the presence of the organ-specific fluorescent antiserum, the failure of islands of morphologically normal but perhaps pre-malignant parenchymal cells to fluoresce is of greater etiological significance.

As the implications of Weiler's work, particularly the demonstration of the loss of organ specificity in pre-malignant cells, bear directly upon the immunological concept of cancer it was considered necessary to confirm his observations. The results of our studies upon the role of the organ-specific antigen during 4-dimethylaminoazobenzene carcinogenesis in the rat liver are presented in this communication.

The methods described by Weiler[2] for the preparation of rat liver mitochondria and microsomes and immunization of the rabbits for the production of anti-mitochondrial and anti-microsomal sera have been followed. However, the rabbit anti-rat liver mitochondrial and microsomal sera were neither organ-specific nor species-specific and generally the sera gave as high a titre by the complement-fixation reaction with rat kidney particulate antigens (mitochondria and microsomes) as with the homologous rat liver antigens. End-point fixation (50 per cent hæmolysis) was observed with dilutions of the rabbit anti-rat liver sera to 1/640 in the presence of the liver antigens, while similar reactions were recorded with the kidney antigens with dilutions of the sera to 1/640 or 1/1,280. Comparable titres were obtained when the antisera were set up in the fixation reaction with mouse liver and human liver antigens. Rabbit antisera have also been prepared to rat kidney microsomes and mitochondria and again these sera exhibited neither organ nor species specificity in complement-fixation tests.

We have observed that the particulate rat liver antigens frequently agglutinated the indicator system (hæmolysin-sensitized sheep's red blood cells) and this phenomenon may account for the somewhat lower titres of the anti-liver sera against the homologous liver antigens when compared with the titres obtained in the presence of the heterologous kidney particulates. The results of the serological studies are thus in accord with the observations described by Macfarlane and Datta[6].

Following absorption of the anti-rat liver mitochondrial and microsomal sera with rat kidney particles, parallel drop in the serum complement-fixation titre was observed in the presence of both the liver and the kidney particulate antigens, and the antisera showed titres of 1/40 and 1/80 after the sixth absorption. All absorptions were carried out at 37° C. for 1 hr. and overnight at 3° C., as described by Weiler[2]. Thus absorption of the antisera with the heterologous antigen did not yield organ-specific sera.

Although a liver-specific antiserum has not been produced we have observed differential staining in sections of liver obtained from rats fed the carcinogen 4-dimethylaminoazobenzene. Non-staining areas of parenchymal cells, similar to the areas described by Weiler[2], were evident when the liver sections were treated with fluorescein-conjugated rabbit sera, but the difference was seen equally well with conjugation from normal rabbit serum as with the immune serum. The globulin fractions which were used in the conjugation of the normal rabbit sera did not fix complement in the presence of rat liver and rat kidney particulate antigens. Exhaustive extraction of the fluorescent sera with the rat kidney particles, which Weiler found to remove free fluorescein derivatives, also non-specifically absorbed much of the fluorescein-conjugated protein and greatly reduced the fluorescence of the stain. In later experiments, free fluorescein derivatives were removed from the conjugated sera by dialysis.

In addition to the non-staining areas of frank hepatoma and cholangioma, non-staining islands were seen in most sections of livers of rats fed 4-dimethylaminoazobenzene. Three types of islands were observed, and examination of serial sections stained with hæmotoxylin and eosin showed that these corresponded with inflammatory and biliary cell foci, necrotic and degenerate parenchymal cells and morphologically normal parenchymal cells. The islands of non-staining, but morphologically normal, parenchymal cells were usually observed in sections in which non-staining necrotic areas were also present; these islands may represent an early stage in the evolution of the necrotic lesion. Occasionally we observed the persistence of non-staining islands of morphologically normal parenchymal cells after discontinuing administration of the carcinogen for two or more weeks, and these areas might represent microscopic cancerous or precancerous foci. The persisting non-staining foci may have consisted of cell populations which had directively progressed towards carcinogenesis, possibly by release from homœostatic control by the loss or modification of 'self-marker' recognition characters. Alternatively, the persisting foci might result merely from a process of continuing degeneration and regeneration. Weiler has observed uniform staining in sections of some livers several months after discontinuing feeding the dye to the rats. He attributed the uniform staining to a "reconstitution of organ specific antigen". However, it is difficult to exclude the possibility that in such cases only the necrotic type of non-staining islands had developed during dye administration, and that regeneration of the normal cell population was accompanied by the recovery of normal staining characteristic.

The results of our investigations in no way invalidate the concept that the malignant cell has lost the 'self-marker' recognition unit(s) necessary for the control of multiplication. Indeed, the histochemical appearances observed by Weiler may well be an expression of deletion or alteration of the highly specific dye-binding protein(s) investigated by Miller and Miller[7]. Although we have reproduced the non-uniform staining which Weiler has observed in sections of livers from rats fed on azo dye, we are unable to confirm his interpretation that the loss of organ specificity is involved in the phenomenon.

Effect of Relative Humidity on Rat Breeding and Ringtail

FOR several years we had very great difficulties in the breeding of rats in our laboratory. The troubles occurred from late autumn until early spring. The death-rate of new-born rats was high, and among the survivals ringtail[1] was widespread.

Breeding difficulties have been reported when cages with wire bottoms are used[2]. Symptoms resembling ringtail have been described in essential fatty acid deficiency and 'cold injury' in experimental rats, and in zinc deficiency in the suckling mouse[3].

Dietary changes, as well as use of soft paper as nesting material, failed to effect improvement of the condition. In all experiments we used metal cages with wire bottoms and fronts. As breeding was normal during the summer, the type of cage *per se* could not be the main reason for the difficulties in the winter.

In 1954, Mrs. C. D. Dickinson, of the Royal Free Hospital, London, suggested to one of us (L. R. N.) that control of the relative humidity in the breeding rooms might be rewarding. In Bergen, relative humidity in rooms maintained at temperatures of 21°–22° C. will fall below 40 per cent during winter-time. During periods of low outside temperatures, relative humidities of about 30 per cent are recorded. Since 1954 we have, with considerable difficulty, maintained our breeding rooms at relative humidities above 50 per cent. During the past two winters a humidifier has kept the rooms hygrostatically at relative humidities in the range 55–65 per cent.

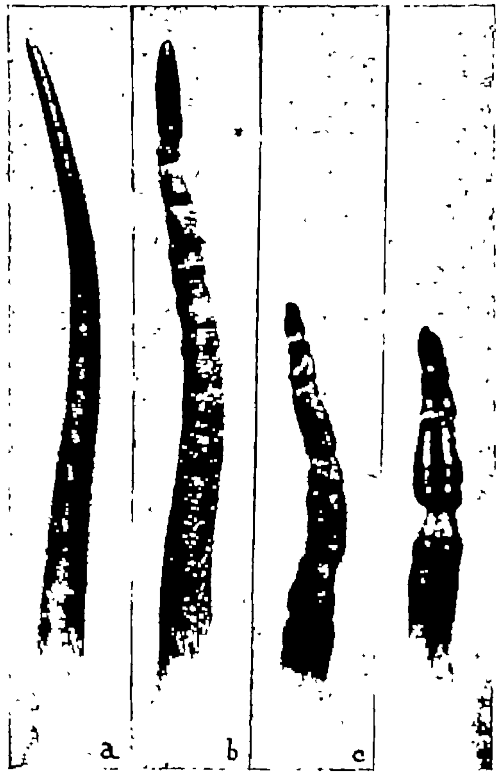

Fig. 1 a, Normal tail; b, c and d, different stages of ringtail

These measures have given very good results: breeding during the winter has been as good as that in summer, and symptoms of ringtail have disappeared almost completely.

The results were so striking that we have continued investigations into the problems. This winter, seven pregnant rats were transferred to a room without humidity control. The young were inspected one week after birth. All of them showed abnormalities of their tails, ranging from slight scaliness to very severe annulation. Some of the rats recovered as time passed. At three weeks, thirty-three out of a total of sixty-three showed various degrees of tail disorders, ranging from slight scaliness over annulation and reddening of the tail tip, to complete necrosis of the tail and its final dropping off (Fig. 1). All young survived the suckling period. Incidentally, the winter was mild so that relative humidity recorded in this room was only slightly below 40 per cent compared with about 30 per cent recorded in earlier winters. This may explain the better survival. In the humidified breeding rooms, sisters of the above females bore and reared sixty-two young, of which only three showed signs of tail disorders.

It is suggested that the reason for the tail disorder observed when relative humidity is low may be a great heat-loss from the naked new-born rat due to evaporation. Arterio-venous anastomoses with relative great diameters are found in the tail of the rat[4]. The rat may therefore reduce its surface area and correspondingly its heat-loss by reduction of the blood flow through the tail. If this be continued for some time, necrosis of the tail may result.

The severity of tail symptoms in rats deficient in fatty acids is reported to be dependent on the relative humidity[5]. This, in connexion with the finding that such rats have an elevated metabolism[6], seems to indicate that heat-loss is counteracted both by reducing the blood flow through the tail and by a greater heat production. This would be in good agreement with our findings.

Work on the problem of ringtail is being continued. It was, however, thought to be of some value to publish this preliminary communication before next winter, in case other laboratories have experienced similar troubles to those related here.

Underwater Sounds heard from Sperm Whales

WHILE the sperm whale (*Physeter catodon*) is one of the more conspicuous cetaceans, it has not figured among the relatively few that have been demonstrated to make underwater sounds, although they have occasionally been suspected of doing so. We have now obtained reliable evidence that they, too, are soniferous.

On March 28, 1957, off the North Carolina coast, our vessel *Atlantis* encountered five sperm whales which permitted the ship to approach as close as 15 metres. During the hour spent with the whales, the engines were frequently shut off to permit listening by means of the echo-sounding receiver. Unfortunately phonographic equipment was not available.

Three types of sound were distinguished. The first, heard before the whales were sighted, was a muffled, smashing noise, with impulses about half a second apart, increasing in intensity to the end of the series. At first it was supposed to be hammering somewhere in the ship, but it was determined that the sound was not made on board. Later, when the whales were in plain sight most of the time, this sound was less conspicuous. A second sound was a grating sort of groan, very low in pitch, which reminded some of a rusty hinge creaking. This lasted as long as five seconds at a time. By far the most common sounds were series of sharp clicks, which were loud enough to blacken the sounding recorder paper, and which usually occurred at intervals of about half a second, but occasionally as rapidly as about five clicks per second. As many as 73 successive clicks were counted. They usually came in groups of 20 or so. Different individuals chimed in from time to time, and there was no period of more than a few seconds without clicks.

The echo-sounding receiver was used for listening on at least thirty different occasions before and after this encounter, and no similar noises were heard.

These observations on *Atlantis* were made by Worthington. It is to be hoped that they will be repeated by others fortunate enough to meet sperm whales, and that they will be supported by phonographic recordings. Although relatively few ships carry broad-band listening and recording gear, many nowadays have echo-sounding equipment. Ordinarily, this can be used for listening, with the transmitter silenced. It is true that most such devices will convey an imperfect version of the sounds heard, since they are designed for a very narrow frequency band centred on the transmitting frequency, and are then often heterodyned well down the spectrum. This, for example, applies to the sounds reported by Worthington, whose equipment selected and emphasized frequencies between 10–17 kc./s. and delivered them to him near 4 kc./s. Nevertheless, at this early stage in our study of marine sounds, such a phonograph record may still be of value, especially if the characteristics of the listening and recording system are known.

While the absence of adequate records makes the matter speculative, it seems likely that the clicks heard by *Atlantis* may correspond to the familiar clicks employed in echo-location by the smaller odontocetes[1]; the 'groan' reported by Worthington may turn out to be a rapid succession of clicks.

Occasionally, in the accounts of the nineteenth-century open-boat sperm whalers, there are allusions to comparable sounds made by the quarry. Thus Bennett's creaking[2] reminds one of Worthington's groan. One of the last of the New Bedford whalers, the late Mr. Henry Mandly, jun., has told Schevill of hearing, in calm weather, impulsive noises from below while waiting in the boats for sperm whales to reappear; these he said were believed to be the whale "snapping his spouters". In spite of the allusions of Davis[3], which describe this act as occurring in air at the surface, it seems improbable that the blowhole as such is involved. Possibly this 'snapping' and Worthington's loud clicks are the same. It is quite likely that the whalers, undisturbed by engine noises, could at times have heard these abrupt under-water sounds.

Note added in proof. On June 4 and 27, R. H. Backus, in our vessel *Bear*, succeeded in making phonographic recordings of sperm whales some 200 miles south of Cape Cod. These recordings closely resemble Worthington's description.

Precision Determination of Cell Dimensions by the Back-Reflexion Weissenberg Method

ALTHOUGH it provides an elegant and accurate means of determining crystal lattice parameters, the back-reflexion Weissenberg method has not been widely used since it was first proposed in 1937 [1,2]. Originally a special camera was built for taking back-reflexion Weissenberg photographs, and it is presumably the lack of this instrument in most crystallographic laboratories that accounts for the neglect

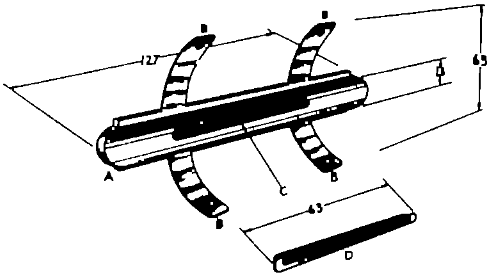

Fig. 1. The Weissenberg back-reflexion adaptor, *A*, fits into the collimator slot of the film holder and is held by the arms *B*. The insert *D* fits into the slit *C*. The approximate dimensions on the figure are given in millimetres

of the method. However, a special camera is not necessary as an ordinary (and widely available) front-reflexion Weissenberg camera can be easily converted into a back-reflexion instrument. The method of conversion described below applies specifically to front-reflexion Weissenberg cameras of the type described by Buerger[2], and may require modification before it can be applied to other designs.

The collimator slot of the film-holder is closed with a removable adaptor machined to have the same internal radius as the film-holder itself (Fig. 1). This adaptor carries a central slit (63 mm. × 3 mm.) for a collimator made of brass tubing having an outside diameter of 1 mm. The film has a slot 63 mm. × 3 mm. cut in it with a special punch and is mounted in the Straumanis fashion. An insert in the collimator slit holds the film firmly against the adaptor and also prevents leakage of light. The conventional layer-line screen is used rotated 90° from the front-reflexion position, the collimator passing through the circumferential slit of the layer-line screen. The beam-stop is mounted on the (removable) lid of the layer-line screen. The camera translation corresponding to a crystal rotation of 240° is reduced to 6 cm. by replacing the bevel-gear on the worm shaft of the Weissenberg mechanism by another bevel-gear with half the number of teeth. The photographs have a distorted scale[1], and central reciprocal lattice rows appear along straight lines slanting at angles of 75° 58′; the maximum Bragg angle that can be recorded on a film holder 57·3 mm. in diameter is 85°. Conversion of the instrument from the front-reflexion to the back-reflexion condition, or vice versa, takes only a few minutes and requires no delicate adjustments; the settings of crystal and camera are not disturbed.

The modified instrument has been used in this laboratory to determine the cell dimensions of a number of orthorhombic and monoclinic crystals. After extrapolation against $\cos^2\theta$ to $\theta = 90°$, the standard deviations of the cell dimensions were about ± 0·0025 per cent in favourable instances. Full details of these results will be published elsewhere.

Crystal Structure of Calcium Monoaluminate

THE crystal structure of calcium monoaluminate ($CaAl_2O_4$) was first examined by Heller[1] in connexion with work on the cementing properties of aluminous cement. Owing to the difficulty of preparing single crystals, a twinned crystal had to be used and the structure was, in consequence, only partially solved. In the present investigation it was possible to cut single-crystal fragments from large crystals selected from a sample of phosphorus furnace-slag[2].

The monoclinic unit cell, space group $P2_{1/n}$, has cell dimensions $[a] = 8\cdot69$, $[b] = 8\cdot09$, $[c] = 15\cdot21 \pm 0\cdot02$ A., $\beta = 90° 8'$, which are substantially the same as those reported by Heller[1]. The observed density of 2·96 gm. cm.$^{-3}$ agrees well with the calculated density of 2·94 gm. cm.$^{-3}$ and indicates that the cell contains twelve molecules of $CaAl_2O_4$.

An interpretation of the *b*-axis Patterson synthesis, taken in conjunction with packing considerations, led to trial structures for two projections. The co-ordinates were refined by means of electron density and difference Fourier syntheses; the final reliability indices were $R_{h0l} = \Sigma(|F_o| - |F_c|)/\Sigma|F_o| = 0\cdot13$ and $R_{0kl} = 0\cdot11$. Finally, structure factors were calculated for 2,400 *hkl* reflexions, to give a reliability index, $R_{hkl} = 0\cdot13$. The structure is shown in Fig. 1.

Calcium monoaluminate, like kalsilite[3] and nepheline[4], is related structurally to β-tridymite[5]. As a result of substituting all the silicon by aluminium atoms, an unusual three-dimensional arrangement of linked tetrahedra is formed.

The calcium atoms are accommodated in cavities caused by the distortion of the tridymite-like structure. Two calcium atoms (Ca_2 and Ca_3) are each surrounded by six oxygen atoms in an octahedral arrangement, at a mean distance of Ca—O = 2·43 A.

Surrounding the third calcium atom (Ca_1) near the two-fold screw axis are nine oxygen atoms, at distances from it ranging from 2·36 to 3·17 A. Six of these oxygen atoms, each shared by two calcium atoms, form an elongated octahedron, thereby forming a continuous chain composed of —Ca$\overset{2\cdot43}{—}$(3) O$\overset{2\cdot53}{—}$Ca—. The remaining three oxygen atoms lie, at a greater distance away (Ca—O = 3·03 A.), in the plane at right angles to the chain. A nine-co-ordinated chain occurs in the mineral fluorapatite[6], but in this case the shared oxygen atoms form a trigonal prism around the calcium atom.

There are twenty-four Al—O distances having values between 1·68 and 1·82 A., and the thirty-six

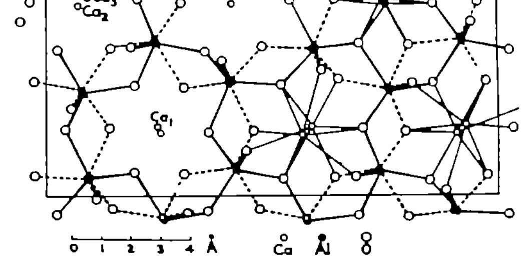

Fig. 1. The *b*-axis projection of $CaAl_2O_4$, showing, on the left, Al—O linkages and, on the right, Al—O and Ca—O linkages. Bonds in lower layer—broken line; bonds in upper layer—full line

O—Al—O angles lie between 101° and 118°. The Si(Al)—O—Si(Al) angles, which in tridymite[6] are all 180°, are in kalsilite[3] straight only in the c-direction; all others approximate to the tetrahedral angle. In calcium monoaluminate, Al—O—Al angles in the pseudo-hexagonal direction have a mean value of 132°, others being approximately 120°.

Full details of this structure will be published elsewhere.

Twinning and the Tabular Growth of Silver Bromide Crystals

SILVER bromide has the sodium chloride-type structure, so that a perfect crystal, growing in a uniform environment, would not be expected to show any tendency to unsymmetrical growth. The fact that dispersions of silver bromide in gelatin, for example in photographic emulsions, can be obtained which do consist of regular polyhedra (Fig. 1) shows that a uniform environment for growth can be obtained. In the same environment during growth, but with different conditions of nucleation, however, dispersions can be obtained in which the crystals are tabular, the tabular faces having triangular or hexagonal shapes (Fig. 2). It can be shown that under identical environmental conditions, the uniform growth in three dimensions of the regular polyhedral crystals proceeds much more slowly than the 'outward' growth of the tabular crystals, that is, the tabular growth is due to enhanced growth parallel to the tabular faces rather than to repression of growth on these faces.

The tabular faces are (111), and, since crystal imperfections are known to promote crystal growth, it can be inferred that the tabular crystals contain some imperfection which promotes growth parallel to the two (111) planes forming the tabular faces.

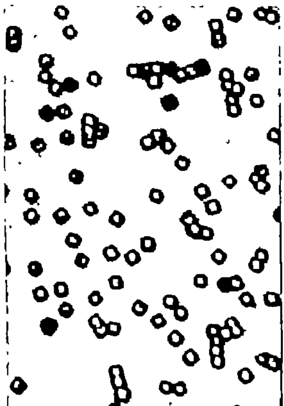

Fig. 1

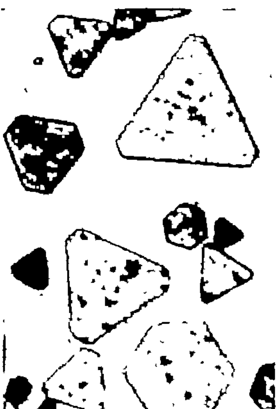

Fig. 2

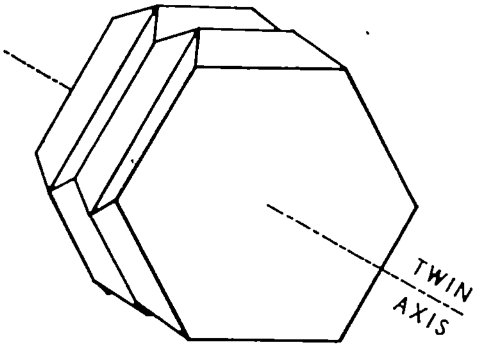

Fig. 3

Twinning is a very common occurrence in crystals, and since in silver bromide a triad axis is the only simple one which could form a twin axis, it is of interest to speculate whether the tabular growth of silver bromide can be explained by twinning.

Successive twinning with a common triad axis will give a crystal of the shape shown in Fig. 3. This possesses two flat parallel (111) faces (tabular faces) perpendicular to the common twin axis, but the 'sides' of the crystal are saw-tooth in cross-section, consisting of alternate 'troughs' and 'ridges', the total number of troughs plus ridges per side being equal to the number of twin planes. Enhanced rate of growth of the sides of the crystal over that on the tabular faces could be explained by making the plausible assumption that the troughs on the sides facilitate nucleation for deposition of successive ionic layers relative to that on the flat tabular faces.

If each twin boundary in the crystal is a single continuous (111) plane, then—if the sides are numbered in rotation 1, 2, 3, 4, 5, 6—sides 1, 3 and 5 form a set of three sides which are identical as regards the number of troughs. Sides 2, 4 and 6 also form a similar set but possess the same number of troughs as the first set only when an even number of twin planes are present in the crystal. For odd numbers of twin planes $(2n-1)$ there will be three sides with $(n-1)$ troughs and n ridges and three sides with n troughs and $(n-1)$ ridges.

If the rate of growth of a side is dependent on the number of troughs on that side, then it follows that the sides in either set of three will all grow at the same rate, but not necessarily at the same rate as the other set of three, that is, the tabular faces will have three-fold symmetry, but not necessarily six-fold symmetry. Tabular crystals with three-fold symmetry of the type shown in Fig. 2 are very common in photographic emulsions.

If the twin planes were formed only in the nucleation stage, then simple ratios between the lengths of adjacent sides might be expected. It is very probable, however, that further twin planes are formed also during the subsequent growth of a crystal, so that the final ratio will not only depend on the number of twin planes present, but also on the times at which each plane was formed during the growth of the crystal.

A Laue photograph taken perpendicular to a (111) plane of a single crystal of the sodium chloride-type structure would only show three-fold symmetry, but if twinning occurs six-fold symmetry would be expected. Laue photographs of this type have been taken in these laboratories, using large (30–50μ across) tabular crystals of silver bromide. Of about thirty crystals examined, ten have given Laue photographs with definite six-fold symmetry. In some of these photographs, one set of spots is much stronger than the other, indicating that the total thickness presenting one orientation is different from the total thickness presenting the twin orientation. This would be expected with, for example, two twin planes, since the two outside portions of the crystal would then have the same orientation, and could increase in thickness; whereas the centre portion, with the other orientation, could not increase in thickness. It follows then that the appearance of a three-fold symmetry in the Laue pattern does not necessarily mean that there is no twinning in the crystal, but merely that the total thickness of one section of the same orientation is insufficiently great to yield a visible Laue pattern.

The twinning hypothesis in its simplest form is not sufficient to explain all the tabular shapes observed in silver halide dispersions, but it can explain those of most frequent occurrence. Twinning on a plane of bromide ions can occur without steric hindrance, and there is experimental evidence to suggest that only this type of twinning occurs.

Twinning in silver halide crystals has been referred to in a paper by Evans and Mitchell[1]. Although those authors consider twinning in silver bromide as unlikely, they think that the development of twinned crystals could explain the formation of certain triangular crystals which they obtained.

Foreign Cations in Silver Azide

THE optical and decomposition properties of inorganic compounds can very often be changed by the introduction of small amounts of foreign cations or anions. For inorganic azides which decompose rapidly on heating, the usual method of incorporating impurities, which involves recrystallization from the melt, cannot be used. Gray and Waddington[1] have reported on the properties of silver azide (AgN_3) containing traces of the cyanamide ion, and this communication is concerned with the method and effect of introducing metal impurities such as cadmium into crystals of silver azide.

The silver azide crystals were prepared from $^{110}AgNO_3$ provided by the Atomic Energy Research Establishment, Harwell. One mode of decay of the silver isotope involves the emission of a β-particle to form cadmium.

The active silver azide was crystallized from ammoniacal solution and stored under water in the dark. A control sample of normal silver azide was prepared and stored under similar conditions. With the sample of silver-110 provided (3·5 mcurie/gm. of silver nitrate) the percentage of silver converted to cadmium after 270 days was approximately 6×10^{-5} per cent. After this period of time the crystals of active silver azide were a reddish-brown colour compared with the normal colourless crystals in the control experiment. The absorption spectra are shown in Fig. 1.

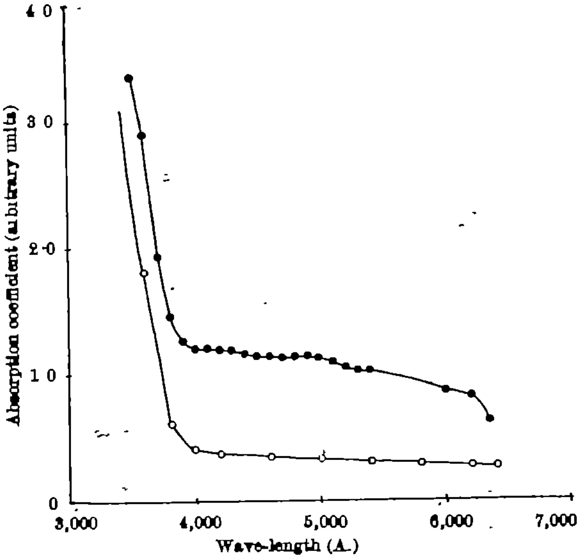

Fig. 1. Absorption spectra of silver azide: ● 'active'; ○, normal

X-ray patterns, from a single crystal and powder of the active silver azide, showed no detectable change from similar patterns of normal silver azide. This was probably due to the fact that the percentage change of silver to cadmium was too small. A further limitation was that silver azide decomposes when irradiated with X-rays, which reduces the length of exposure that may be given. Three hundred days after being prepared, the emission from the active silver azide was still sufficient to give a slight overall fogging of the film in the X-ray camera.

Associated with the change in absorption spectra shown in Fig. 1, there is a change in the variation of refractive index with wave-length (Fig. 2) compared with normal silver azide[2]. This new absorption band also effectively suppresses the photoconductive properties normally exhibited by silver azide. On dissolving a crystal of active silver azide in ammonia, it was found that the reddish colour was present

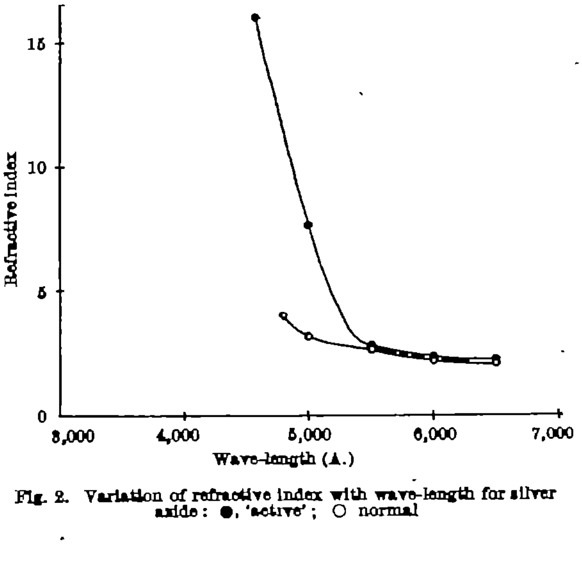

Fig. 2. Variation of refractive index with wave-length for silver azide: ●, 'active'; ○ normal

throughout the bulk of the crystal. A very fine metallic network remained after all the azide had been dissolved. Crystals of active silver azide are also more sensitive to light than normal silver azide.

Cadmium azide normally exists in the divalent form $Cd(N_3)_2$. Thus it is clear that if, as a result of radioactive decay, molecules of cadmium azide are formed then there will be an excess of silver ions. Silver azide has a high ionic mobility at room temperature. It will be possible for the silver ions to acquire the necessary negative charge to give rise to a silver precipitate in preferred regions of the lattice. This is probably responsible for the new absorption spectra[3].

The detonation velocity of long needles of active silver azide was determined by S. K. Deb using metal probes in conjunction with a spiral base cathode-ray oscilloscope. He found the average detonation velocity (m./sec.) of crystals of length about 1 cm. and diameter 0·3–0·4 mm. when ignited by a hot platinum wire is: pure silver azide, 1,500; 'active' silver azide, 2,200.

This 50 per cent increase in detonation velocity may be due either to the presence of $Cd(N_3)_2$ molecules or to the finely dispersed silver. The latter mechanism is considered the more probable as it has been shown that normal silver azide may be sensitized to flash initiation by incorporating gold powder in compressed pellets of silver azide (Evans, B. L., and Yoffe, A. D., unpublished work). The metal acts as an electron trap and increases the rate of decomposition.

The introduction of cadmium and consequent formation of free silver have thus been responsible for a considerable modification in the properties of silver azide crystals. It is interesting that the presence of such small concentrations of impurity (< 1 in 10^6) can bring about this marked change in detonation velocity.

We are grateful for the assistance given by Dr. J. Sawkill, and for the encouragement afforded us by Dr. F. P. Bowden.

A Hydrogen-Conversion Detector for Gas Chromatography

The thermal conductivity cell is in common use as a detector in gas chromatography. When separating high-boiling compounds it is necessary to heat the cell to avoid condensation effects, but with nitrogen as the mobile phase this results in loss of sensitivity. The use of hydrogen or helium instead of nitrogen is said to improve sensitivity but apparently gives broader peaks and less resolving power[1,2]. Using nitrogen as the carrier gas, Martin and Smart[3] obtained improved sensitivity by converting the compounds as they emerged from the column into carbon dioxide and water, and detecting the carbon dioxide by an infra-red gas analyser. In this laboratory this technique has been tried using a thermal conductivity cell to detect the carbon dioxide after removal of water vapour. In our experience this method gives increased sensitivity but is accompanied by some band spreading and consequent loss of resolution.

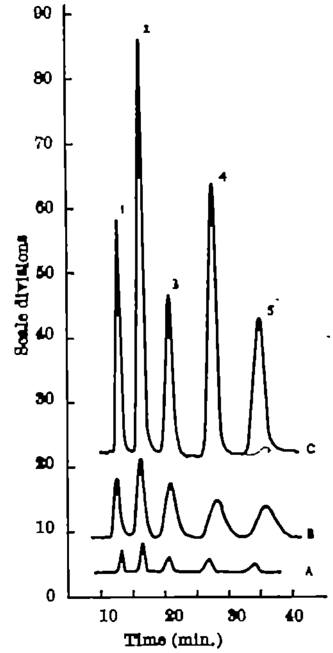

Fig. 1. Chromatograms of equal weights of a mixture of (1) cinnamaldehyde, (2) butyl benzoate, (3) coumarin, (4) phenyl propyl butyrate, (5) β-naphthyl methyl ketone. Nitrogen flow, 13 ml/min. Column temperature 195° C. Curve *A*, normal system, catharometer temperature 122° C., total sample 1 mgm. Curve *B*, conversion to carbon dioxide, total sample 1 mgm. Curve *C*, conversion to hydrogen, total sample 1 mgm.

Much improved sensitivity with excellent resolution is obtained by converting the water vapour to hydrogen and removing the carbon dioxide. The increase in sensitivity is due to the much greater difference between the thermal conductivities of hydrogen and nitrogen than between those of carbon dioxide and nitrogen. The increase in sensitivity can be seen by reference to Fig. 1. The three curves represent the separation of the same mixture of five high-boiling compounds containing carbon, hydrogen and oxygen only, the same sample weight being taken in each case. Curve *A* shows the trace (Sunvic recorder 0–2·5 mV. range) using an electrically heated thermal conductivity cell running at 122° C. This was found to be the lowest temperature at which the cell could be run to avoid condensation effects, the compounds boiling in the range 250–300° C. Curve *B* shows the trace after each compound had been converted to carbon dioxide, the thermal conductivity cell now operating at room temperature. Curve *C* shows the trace after conversion to hydrogen and removal of carbon dioxide. The peaks in this case occur in the opposite direction, but are shown reversed for clarity. A tube 4 mm. in diameter and 5 ft. long packed with 20 per cent w/w silicone grease and 'Celite' 545 was used for the separation in the manner described by James and Martin[4].

The hydrogen converter is simply made from a 30-cm. length of silica tubing 4 mm. in diameter, packed in two 10-cm. sections, one filled with copper oxide and the other with iron powder. The whole tube is heated electrically to red heat. From this combustion tube the gases pass first through a short column of soda-lime to remove carbon dioxide, and secondly through a small glass spiral immersed in oil to ensure complete cooling, before passing into a conventional straight wire thermal conductivity cell.

The converter can be used with any apparatus where a thermal conductivity cell is the detector, and could perhaps be used to increase the sensitivity of other types of detector.

Thanks are due to Dr. J. R. Hawthorne for his encouragement, and to the directors of Schweppes, Ltd., for permission to publish this communication.

Photoperiodicity and Wool Growth in Romney Rams and Wethers

PHOTOPERIODIC control of the breeding season in several breeds of sheep has been demonstrated by Yeates[1] and others, and the effect of light as a stimulant to growth and shedding of hair in some mammals has also been investigated. Some wool-production responses of New Zealand Corriedale ewes to photoperiodic stimuli have been described by Hart[2,3]: ewes which had endured constant artificial light/dark rhythms produced for several months a greater weight of wool than they had done before the treatment and greater than control ewes subjected to the normal solar-light rhythm. It is thought that, succeeding the initial reception by the eyes of the light stimulus, impulses travel neurally to the hypothalamus and from there the activity of the adenohypophysis is controlled possibly by a neuro-humoral link; the activity of the adenohypophysis may then influence the rate of wool growth either by thyrotrophic or growth hormones. Hart[3] supplied evidence supporting the view that "the photoperiodic response in wool growth may be due to an increased thyrotrophic activity of the pituitary"; in one experiment he subjected a group of ewes to a fixed rhythm of two hours light to four hours darkness and after a latent period there was a marked response in wool growth by these animals. Hart cited this result in support of the 'contrast sensitivity' theory of reaction by the complex responsible for the expression of photoperiodic stimuli.

An experiment was commenced at the Rowett Research Institute, Aberdeenshire, by this department on June 1, 1955 (pre-experimental period March–May), and it was designed with the following objectives: (1) Generally, to investigate wool growth responses by English Romneys to photoperiodic stimuli, using control sheep subjected to the normal seasonal solar-light–darkness rhythms experienced in Scotland. (2) To find out the wool growth responses to light stimuli by wethers and rams. So far as we know, these have not been previously investigated and such material was, of course, not complicated by events in the oestrous cycle. (3) To obtain evidence of possible responses in the form of the degree of fibre shedding.

A group of twelve Romney Marsh sheep, consisting of four rigs, one ram and seven wethers, were tested and ranked for level of clean wool production from tattooed squares during a pre-experimental period; they were then allocated to either the control or the experimental group, each numbering six sheep. From June 1, 1955, both groups were indoors in individual pens and fed exactly the same ration of concentrates and chopped hay with water *ad libitum*. The control group experienced natural solar-light–darkness rhythms throughout and the experimental group was in an adjacent blacked-out room, enduring a continuous fixed 2 : 1 rhythm of eight hours darkness to four hours electric light supplied by two 100-watt bulbs: this rhythm was maintained without alteration during the period June 1955–October 1956. Mean weekly temperatures were approximately the same in experimental and control rooms, the temperature not being controlled but varying with season. Wool from each of four tattooed areas on each sheep was cut at skin-level every two months, receiving a standard washing and the weight being determined under standard conditions. Results have been statistically analysed. The areas of the tattooed squares were measured at each sampling time and skin samples taken periodically for *S/P*, and other information which will be communicated in a more detailed account of the experiment to be published later. The treatment ended on October 17, 1956, when all the sheep were put outside; shortly after this the feeding of concentrates to both groups ceased. No attempt was made to test by injection any effects on wool growth of specific hormones.

Fig. 1 shows the total clean conditioned weight of wool grown during successive two-monthly periods

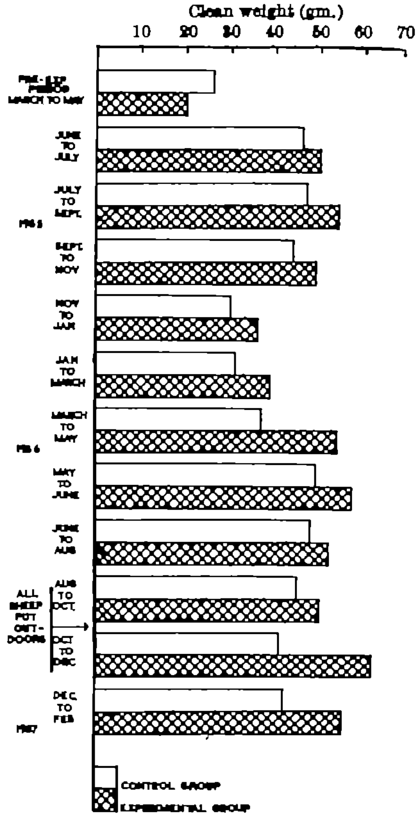

Fig. 1. Weight of clean wool conditioned to 67° C., 68 per cent relative humidity from tattooed squares

from the tattooed skin areas (this expresses the changing capacity for wool production better than it would be expressed as weight per unit area of skin). Results obtained so far may be summarized as follows:

(1) Results agreed with those of Hart in supporting the 'contrast sensitivity' theory of response in wool growth to photoperiodic stimuli.

(2) Although at the end of the pre-experimental period the sheep in the experimental group had produced less clean wool from their marked areas than that grown by the marked regions of the controls, during the period August–September 1955 they had begun to produce a significantly greater weight of wool than that grown by the controls. There continued to be a margin between the two groups until during March–May 1956 the experimental group reached a peak, producing about 48 per cent more wool than the controls. The margin between the two groups was then gradually reduced through the summer until October of the same year (1956). The remarkable rise in production of clean wool (approximately 50 per cent more than the controls) by the experimental animals during the two months (October–December) immediately following the conclusion of the experimental period indoors is shown in Fig. 1. This occurred in spite of the fact that (*a*) wool production of the control animals had declined, (*b*) the value of the pasture was beginning to deteriorate at this season, and (*c*) both control and experimental animals were now together outdoors under the same conditions. During the following period, December–February, the margin, although slightly reduced, was still high. Sampling will continue and it is hoped to elucidate further the responses in these and other sheep. It is clear, however, that this high production during four months of what is normally a low wool-producing season has significant practical implications.

(3) The difference in wool production between the two groups changed significantly with time during the experiment (groups × times interaction significant at the 0·1 per cent level).

(4) Seasonal variations in wool production have been described before: again in this experiment a seasonal variation with a peak each summer has been demonstrated by both groups while they were housed, and the variation is independent of either level of feed or photoperiodicity.

(5) The curve for mean monthly ambient air temperatures was closely followed by those for clean-wool production of both groups throughout the experiment. It is not certain that external temperature had an immediate and direct effect on seasonal variation in wool production, but it is probable that variation in temperature was a contributory factor.

(6) From a wool-production point of view, rams and rigs behaved no differently from the wethers.

I am grateful to Dr. D. P. Cuthbertson, director, J. C. Gill, J. Wood and others on the staff of the Rowett Research Institute for facilities and maintenance of sheep during the experiment; also to R. Bell for statistical analyses and to Mrs. S. Webster, research assistant in this Department, for her skill and care in recording data and other work connected with the investigation.

A. B. Wildman

Anisotropy of Sclerotinites

Seyler[1] has measured the reflectance of sclerotinites but has not commented upon the existence of anisotropy in them.

I have found distinct anisotropy in some sclerotinites obtained from coals of widely different geological periods and of widely scattered areas throughout the world. Reflectance measurements have been made in oil and the relation of maximum reflectance (R_1) to minimum reflectance (R_2) has been plotted in Fig. 1. For comparison, the measurements of R_1 and R_2 in respect of vitrinites of different ranks obtained by Broadbent and Shaw[2] have been plotted in the same figure. It will be seen that this relation with sclerotinites and vitrinites appears to follow a straight line up to the R_1 value of about 3 per cent. At this stage the results with vitrinite deviate from the linear relation.

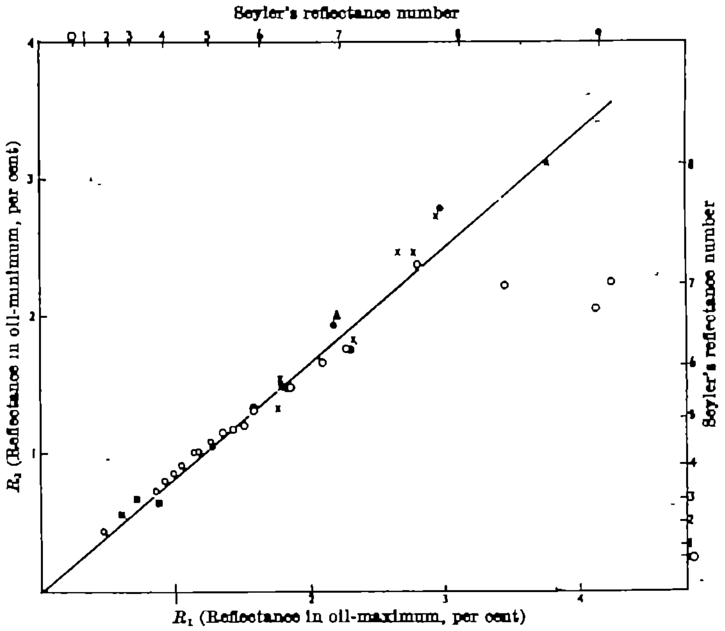

Fig. 1. Relation of maximum (R_1) and minimum reflectance (R_2) in oil for sclerotinite and vitrinite. Sclerotinite: ●, Carboniferous, Barnsley seam, England; ▲, Carboniferous, Harraton Small, England; ×, Permo-carboniferous, Wankie Coal, Southern Rhodesia, Africa; ■, Eocene, lignite from Palana, India. Vitrinite: ○, British carboniferous coals

It will be of interest to ascertain if the values of R_1 and R_2 for other micro-constituents of coal follow similar relations.

FORTHCOMING EVENT

Monday, August 12—Saturday, August 24

INTERNATIONAL SOCIETY OF SOIL MECHANICS AND FOUNDATION ENGINEERING (at the Institution of Civil Engineers, Great George Street, London, S.W.1)—Fourth Conference.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN VETERINARY PHYSIOLOGY—Secretary of University Court, The University, Glasgow (August 15).

ASSISTANT LECTURER IN STATISTICS—The Secretary, Birkbeck College, London, W.C.1 (August 16).

HEAD (highly qualified and with suitable industrial and/or research experience, and preferably some full-time and/or part-time university or technical lecturing experience) OF THE DEPARTMENT OF APPLIED PHYSICS, Brunel College of Technology, Woodlands Avenue, Acton, London, W.3—The Clerk to the Governing Body, Middlesex County Council Education Department, 10 Great George Street, London, S.W.1 (August 16).

DEMONSTRATOR (preferably with an honours degree in agriculture or agricultural science) IN AGRICULTURE at the School of Agriculture, Sutton Bonington—The Registrar, The University, Nottingham (August 17).

LECTURER (preferably with major interests in heat transfer thermodynamics, mechanisms or machine design) IN ENGINEERING (MECHANICAL) with which Nuclear Engineering is combined—The Registrar, The University, Manchester 13 (August 17).

PHYSICISTS and ELECTRONIC ENGINEERS (with a degree or equivalent qualification, and the ability to apply fundamental knowledge to a wide variety of problems) IN THE ELECTRONICS AND INSTRUMENTS SECTION of the Central Electricity Authorities Research Laboratories at Leatherhead, Surrey, to work on problems of vibration, acoustic noise, or radio interference—The Director of Establishments, Central Electricity Authority, Winsley Street, London, W.1, quoting Ref. N/327 (August 17).

READER IN MATHEMATICS, preferably in MATHEMATICAL PHYSICS; and a LECTURER IN MATHEMATICS—The Registrar, College of Technology, Birmingham 1 (August 17).

SENIOR LECTURER IN PSYCHOLOGY in the Department of Management and Production Engineering—The Principal, Brunel College of Technology, Woodlands Avenue, Acton, London, W.3 (August 17).

ASSISTANT LECTURER IN THEORETICAL PHYSICS—The Secretary, Birkbeck College, Malet Street, London, W.C.1 (August 20).

SCIENTIFIC/SENIOR SCIENTIFIC OFFICER (with a first- or second-class honours degree or equivalent) in the National Physical Laboratory (D.S.I.R.), Teddington, for research into dating by radioactive methods including setting up of equipment for the measurement of carbon-14 in archæological specimens—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.361/7A (August 24).

SENIOR RESEARCH STUDENT IN EITHER ENGINEERING OR CHEMICAL ENGINEERING OR METALLURGY—The Registrar, University College, Singleton Park, Swansea (August 28).

DEAN OF THE FACULTY OF MEDICINE, University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, August 31).

PRINCIPAL (with high academic and, if appropriate, professional qualifications, proved administrative ability and experience (preferably partly overseas) in the administration of an educational institution) OF THE ROYAL TECHNICAL COLLEGE OF EAST AFRICA, Nairobi—The Council for Overseas Colleges of Arts, Science and Technology, 1 Woburn Square, London, W.C.1 (August 31).

SENIOR LECTURER or LECTURER (with a university degree in chemical engineering or a degree in chemistry followed by industrial experience of chemical engineering work) IN THE DEPARTMENT OF CHEMICAL ENGINEERING—The Registrar, King's College (University of Durham), Newcastle-upon-Tyne (August 31)

JUNIOR LECTURER IN ZOOLOGY—The Registrar, Trinity College, Dublin (September 1).

LECTURER or ASSISTANT LECTURER (with a higher degree in biochemistry or physiology) IN BIOCHEMISTRY in the Department of Physiology and Biochemistry—The Secretary and Registrar, The University, Southampton (September 7).

SENIOR LECTURER IN ANIMAL HUSBANDRY at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 7).

LECTURER or ASSISTANT LECTURER IN THE DEPARTMENT OF GEOLOGY—The Deputy Registrar, The University, Birmingham 15 (September 10).

LECTURER IN CHEMISTRY (ORGANIC) at Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, September 15).

LECTURER IN GEOLOGY at Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, September 15).

GEOLOGIST (with a degree or equivalent in geology, and a satisfactory knowledge of (*a*) petrology and mineralogy or (*b*) stratigraphy and palæontology) IN THE GEOLOGICAL SURVEY—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (October 10).

ASSISTANT EXPERIMENTAL OFFICER (with at least H.S.C. (Science) or equivalent and preferably a knowledge of radioactivity and some previous experience in chemical analysis), for work in the assessment of low activity levels in biological materials—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. 1544/34.

CHEMISTRY GRADUATE for research work in the Chemistry Department on problems of physical-organic chemistry with particular relation to organo-phosphorus compounds—The Registrar, Queen Mary College (University of London), London, E.1.

LECTURER, Grade B (with a general science degree in chemistry and physics and a diploma in education, or the equivalent, with teaching experience) IN THE DEPARTMENT OF HEALTH EDUCATION; and a LECTURER, Grade B (with an honours degree in physics, and preferably research experience) IN THE DEPARTMENT OF PHYSICS—The Clerk to the Governing Body, Battersea College of Technology, London, S.W.11.

LECTURER IN PHYSIOLOGY OF THE SHEEP—The Registrar, Massey Agricultural College (University of New Zealand), Palmerston North, New Zealand.

RESEARCH ASSISTANT (graduate in physics)—The Secretary and Registrar, The University, Southampton.

SENIOR LECTURER IN ELECTRICAL ENGINEERING at Bradford Institute of Technology—The Director of Education, Town Hall, Bradford.

SELECTION OF UNIVERSITY ENTRANTS

APART from the plans for expansion to meet the growing demand for scientific and technological man-power in Britain to which both the Zuckerman Committee's report on Scientific and Engineering Man-power in Great Britain and the earlier report on the Recruitment of Scientists and Engineers by the Engineering Industry have directed attention, it is now generally realized that the universities are called upon to expand to provide places for the larger number of young people who may be expected to seek entry from 1960 onwards in consequence of the post-war rise in the birth-rate. The current expansion, however, is not being planned solely to meet a temporary situation, but to provide for a permanent increase of about half as many students as the universities are now accommodating. The report on "Early Leaving" suggested that there is a considerable reservoir of talent capable of profiting by a university education, which does not at present reach the universities. It is natural, therefore, that concern should be expressed as to the numbers involved and how far the universities could and should be expected to expand without either lowering their standards or running undue risk of excluding those who were capable of profiting by a university training.

With State expenditure on university education in Britain approaching £40 million a year, apart from expenditure on technological education and large sums for capital expenditure, due care must obviously be taken to see that money is not wasted on those incapable of profiting by further education, as well as to ensure that the best use is made of the money. This involves more than an attempt to see that the disposition of resources between different university departments is in proportion with the needs of the State and the demand for particular types of trained men and women, that full use is made of the facilities provided and that there is no uneconomic and wasteful distribution of facilities between different universities. It is also a matter of finding students with adequate qualifications at entry, and of seeing that standards of teaching are maintained for the larger numbers and not debased either by lowering the staff–student ratio or by lack of equipment and accommodation.

In these conditions the question of how many qualified applicants at present fail to gain admission to a university assumes fresh importance. The lack of places for all the school-leavers who could satisfy minimum requirements and wished to enter a university during the immediate post-war years had led to competition conditions in which school-leavers tended to send applications to several universities in the hope of finding a place at one of them, and this persisted after 1950 even when the expansion of the universities and decrease in the number of ex-Service students had made it possible for the universities to take many more applicants. Increased numbers of State scholarships and local education authority awards had, in the meantime, made a university education possible for many young people who would not otherwise have been able to afford it; but the opinion was widely held that no really worthy applicant was failing to find a place somewhere or other, even if it was not necessarily in the university of his or her first choice.

Nevertheless, from several points of view, it was important to find an answer to the question, if possible, and in January 1952 the Committee of Vice-Chancellors and Principals appointed a sub-committee, with Sir James Mountford as chairman, to inquire into the situation. A report on this inquiry has now been published*, which is of considerable interest in this and in a wider context. The inquiry sought in the first place to provide answers to such questions as: how many applications for entry are received and considered by universities in a single session; how many individual students these applications represent and how they are distributed between the different subjects of study; how many of the applicants are offered and accept places; the reasons some applicants are not offered a place anywhere; and how many places in the various subjects of study are available and how many of them are filled. Although the report is limited to the single year 1955–56—representing accordingly a snapshot of the situation at one particular time—and although its material is not homogeneous and is of variable reliability, it has a wider interest, because the opportunity was taken to collect information about the previous educational background of the applicants, their social antecedents, the sources of their financial support and the careers which, at the time of application, they proposed to pursue. The replies to some of these inquiries are naturally of variable reliability; but none the less, the report throws real light on some important questions, answers to which are desirable if the expansion of university and technological education is to be planned so as to make the best use of available resources.

Between May 1954 and the autumn of 1955 some 70,000 applications, representing 22,000 men and 9,000 women, were received for admission in 1955–56 to full-time university courses in Britain leading to a first degree or diploma; and on an average those with addresses in Great Britain and Northern Ireland applied to more than two places, the number of applications per applicant being highest in the faculties of medicine and science. About 18,000 applicants were known to have been admitted at the beginning of the 1955–56 session, and of the remaining 13,000 less than a quarter were women. Less than 10 per cent of the men admitted came from overseas; but the proportion of overseas applicants admitted was very much higher in dentistry and technology than in other faculties. About two-thirds of the overseas applicants, both admitted and non-admitted, were from countries within the British Commonwealth.

---

* Report on an Inquiry into Applications for Admission to Universities. By R. K. Kelsall. (Committee of Vice-Chancellors and Principals of the Universities of the United Kingdom.) Pp. vi+32+27 tables. (London: Association of Universities of the British Commonwealth, 1957.) 17s. 6d.; 3 dollars.

The material relating to the educational background of the applicants is complicated and difficult to summarize, but some points of interest may be noted. Cambridge (34 per cent) and Oxford (42) had the lowest proportion of applicants who had attended local authority primary schools, followed by London (59), The Queen's University of Belfast (68), Scotland (71), other English universities and colleges (74) and the University of Wales (88); but some of these differences reflect, in part, the relative importance of different faculties in the various university groups. There were indeed wide variations in the proportion of local authority primary scholars in the different faculties, the proportion being highest in science (75 per cent) and technology (71 per cent) and lowest in medicine (49 per cent; in Oxford, 20; and in Cambridge, 24). Excluding Oxford and Cambridge, more than 10 per cent of the students from Great Britain applying for admission said that they had been boarders at the last secondary school they had attended; at Oxford and Cambridge the proportion of secondary school boarders among British students admitted exceeded 40 per cent. Among those not admitted, 91 per cent of those proposing to study science were day pupils, compared with 73 per cent for dentistry and veterinary science and 76 per cent for medicine; the corresponding proportions of those not admitted who had been at grammar schools maintained by local education authorities were 75, 54, 60 and 53 per cent, respectively.

These figures certainly suggest that local authority schools are providing a reasonable proportion of those seeking to study science and technology; but this aspect of the inquiry, and also the material relating to the social background, is best considered after dealing with the evidence about the 13,000 who were not admitted, some 2,000 of whom were overseas applicants. About 10 per cent of this total received an unconditional offer of a place either for 1955–56 or for a later session from at least one university. At the other extreme, about 25 per cent of the applicants did not, when their case was last considered, possess the necessary paper qualifications for admission to the course of study they proposed at any university to which they applied. These two groups accounted for about 4,500 of those not admitted anywhere; and although it was difficult to obtain further information about the qualifications of the overseas applicants from further information supplied by the universities, regarding the 6,900 British candidates involved, it seems probable that at least a third of them had all the paper qualifications needed for entry on their proposed course in at least one of the universities to which they applied.

Thus, out of some 11,000 candidates from Britain who were not admitted, about 25 per cent did not possess the necessary paper qualifications, although, in addition to the 10 per cent who were offered places unconditionally in 1955–56 or a later session, at least 21 per cent had all these qualifications. It would seem that the university or college did not in fact always know whether the applicant possessed the minimum paper qualifications when it was not worth while seriously to consider the candidate's suitability because, for example, all places were filled. The universities and colleges participating in the inquiry reported, however, some 2,500 unfilled places at October 1955; but well over half these places were in arts subjects, whereas less than 37 per cent of those not admitted came within these subject groups. Again, some of the unfilled places were due to the failure of applicants for whom they had been reserved to notify the university or college concerned that they were not proposing to fill them, until it was too late to offer the places to others.

Nevertheless, it remains true that a relatively small number of fully qualified applicants, if they had known of the existence of these vacant places in universities and colleges to which they had not applied, might have secured admission there. The number of vacant places may be small and to some extent may be temporarily unavoidable, though a central clearing house for applications might well help to accelerate the filling of last-minute and unexpected vacancies; and the idea might well merit consideration by the universities, if indeed they have not already examined it. It would seem, however, that there is at present a significant number of qualified applicants for whom the universities cannot find room, and the direct approach made in the autumn of 1956 by Sir James Mountford's Committee to a representative sample of British students who were not admitted was designed to throw more light on the problem.

The outstanding result of this further inquiry, which obtained so good a response that the answers can be taken as broadly applicable to the group as a whole, was to show that more than a third of applicants in Great Britain had, within a year of the beginning of the 1955–56 session, been admitted to some institution of university rank. The sample also showed that a further 6 per cent had offers of university places for a session later than 1956–57, usually at Oxford and Cambridge; and it seems, therefore, that we are left with only the 7,000, or 63 per cent of the original total of British students not admitted; and these, according to the information obtained from the universities, either did not possess all the entrance qualifications or their position was doubtful. The sample inquiry provided no firm answer to the question of what proportion of these 7,000 afterwards obtained the necessary qualifications; but it seems possible that between 2,000 and 3,000 people who at least fulfilled the London minimum degree entrance requirements in October 1955 failed to secure admission to any university either then or in 1956–57, or to have a place reserved for them in a later session. Of this 7,000, it would appear that some 1,600 were in full-time attendance at other types of further education institutions, such as teachers' training colleges, by the autumn of 1956.

The report submits no recommendations, and the Sub-Committee draws no firm conclusions; but the material submitted suggests that the problem is not intractable and should yield to some measure of central organization and co-operation, such as the clearing house for applications already suggested. These measures could well begin if Government support leads the universities to expand in faculties designed to supply the State with the particular categories of practitioners it needs; for although at the moment those not admitted favour science subjects rather than arts subjects, there can be no guarantee that the needs of the State and the aspirations of the would-be university entrant will always run together. The report at least hints at a problem which could become more acute, and lead to graduate unemployment if unheeded.

No less important and suggestive, however, are the chapters of this report which discuss the evidence on social background, financial assistance and the occupation the candidate had in mind. The latter evidence could well be the most unreliable, and seems to show the large opportunity for public relations work, emphasized in the White Paper on Technical Education and elsewhere, in order to enable the nation to recruit the much larger numbers of scientists and technologists it needs. It is interesting to note that the sons of teachers are much less prone to enter their fathers' profession than are the sons of medical men and dentists, and while 15 per cent of the men admitted who proposed to enter the medical profession were themselves the sons of medical men, for the teaching profession the proportion was only 5 per cent.

The differences between university groups in the proportion of their entrants receiving no financial assistance or help of one kind rather than another were largely associated with the differing proportions in which their entrants were drawn from the main social classes, though another important factor was the proportionately greater number of university and college awards available in some university groups rather than in others, and the preferences shown for particular universities by holders of awards not tied to a specific university or college. The most revealing of these sections, however, is that which points out, in line with the conclusions of the report on "Early Leaving", that the children of manual workers form a very much smaller proportion among those applying for admission to universities and colleges in Great Britain and Northern Ireland than manual workers form of the adult male population as a whole. Differing environmental influences and aspirations are regarded as much more important than any hereditary influence on the distribution of intelligence in reducing the proportion of boys with manual-working fathers from 66 per cent at the point of entry to the non-fee paying grammar school to 36 per cent at the point of university entry (or 26 per cent if we include university entrants from the direct grant and independent schools).

It is probable that, as the report on "Early Leaving" suggested, much good material is being lost which could increase our supplies of technologists and scientists. If, however, this source is ever to contribute to the supply of technicians, positive measures will be required to deal with the environmental influences and such factors as lack of parental ambition. It may well be necessary to go even deeper, for a tradition of culture and service may also be involved. We cannot encourage materialism and expect an altruistic response. Although this report gives a somewhat reassuring answer to the main inquiry, the mass of material presented affords abundant material for thought, and for further inquiry about the universities themselves. While the universities must maintain their tradition of sound learning and free inquiry, they must also supply the nation with an unending succession of men and women competent not merely to undertake offices in the State with imagination and integrity, but equally to bring to the service of industry and the myriad vocations of the modern world those both technically and professionally competent and alive to the human issues and values with which they will be confronted. If Sir James Mountford's committee has done nothing else, it has given a hint that the universities may have to discard some of the assumptions they make about their students, and work out new methods and new standards for dealing with the applicants for admission now coming forward.

TECHNICAL PROGRESS IN BRITISH INDUSTRY

Industry and Technical Progress

Factors Governing the Speed of Application of Science. By C. F. Carter and B. R. Williams. Pp. viii+244. (London and New York: Oxford University Press, 1957.) 25s. net.

THIS book is good enough, and authoritative enough, to make its defects important. It leaves the reader convinced that the authors have themselves achieved a thorough and balanced understanding of the factors upon which technical progressiveness depends, but perhaps equally convinced that this understanding would have been transmitted better if the material had been presented more briefly and with some selective emphasis.

It can be assumed that the authors had no wish to induce or support complacency, yet it may prove that they have done so in one important respect. To demonstrate the objectivity of their approach, which is generally well sustained, they emphasize, in Chapter 1, that they did not start by accepting the view that British industry is less progressive than that of some other countries. They then go on to point out, quite rightly, that some sections of industry are at least as progressive as their counterparts in any other country. Unfortunately, having declared their refusal to accept the generalization before investigating it, and having made reference to special cases which seem to be at variance with it, they do not return to the matter and express any final opinion based upon their studies. As a result, they leave any reader free, if not encouraged, to conclude that British industry is as technically progressive as industry in any other country. It is true that this is not stated to be so, nor is it likely that the authors believe it, but they blunt a potentially powerful spur to action by leaving the matter in doubt.

The failure to draw conclusions as to the technical progressiveness of industry in Britain relative to that of other countries is due, in part at least, to the failure to find any quantitative means of assessing progressiveness. Throughout the book, the judgment of progressiveness is subjective and qualitative. Although the authors recognize the danger of confusing features regarded as evidence of progressiveness with the factors considered to lead to it, it is a danger which they are unable to avoid completely. This difficulty would have been reduced, and the force of the conclusions presented would have been increased, by the adoption of reasonable, even though admittedly imperfect, quantitative methods of assessment. One such method, well suited for comparison between the state of technical advancement of the whole manufacturing industry of one country and that of another, is to compare added value produced per employee hour, after correcting for differences in the value of money. This measures industrial output in terms of the value set upon it by the consumer, and includes allowance for the technical sophistication of the products. When applied to the whole manufacturing industry of a nation, it gives a sensible measure of the manner in which the basic resource of man-power is reinforced by all those other factors which the authors rightly regard as important, such as manual and mental skills, balance between parts of industry, development and production of efficient equipment, effective use of capital, and general good management.

The same form of measurement is of less value when applied to inter-company comparisons, because there is less justification for regarding individual companies as self-contained systems and similar in kind. Even in this context, however, and particularly for comparisons between units within some one section of industry, measurement of corrected added value per employee hour, or the rate of change of this quantity, could usefully be used as one of several non-subjective means of measuring technical progressiveness.

The authors make a very comprehensive survey of the factors which permit or cause a company to be technically progressive. In doing so, they lay further stress upon some matters already recognized to be of importance, but they also emphasize the importance of other factors which tend to be overlooked. Thus, while they reinforce the generally accepted view that the supply of technologists and scientists is inadequate to enable industry to be as progressive as it should be, they also point out that many sections of industry are disinclined to use scientists at all, and that many scientists who are employed in industry are very inefficiently used. Also, while recognizing the importance of the continuing search for new knowledge, the authors stress the necessity for industry to develop an urge to find, and an ability to use, knowledge already available. As they say, in Chapter 4, "There are many firms in craft industries which have not even taken advantage of 'school text book' scientific principles. Their real problem is not that scientific knowledge is hard to come by, but that they have not begun to want it".

A theme strongly expressed throughout the book is that scientific knowledge and ability must be an integral part of management's equipment; that research needs to be managed in relation to appropriate company objectives, and that there must be ability to comprehend and use the results of research outside the research department as well as appreciation of company objectives within it. Not surprisingly, in relation to these views, the authors conclude that technical progressiveness is seldom found where management is not progressive in its general outlook.

During the course of their discussion of the causes of technical progressiveness, the authors go some way towards disarming earlier criticism by devoting attention to demonstrating the weakness or falsity of most of the arguments used by apologists to explain why Britain is less technically progressive than some other nations. They also show that none of the external factors which tend to obstruct the technical progress of an individual firm is likely to be so serious as defects in its own management.

R. BEECHING

A NEW COSMOLOGY

The Dramatic Universe

By J. G. Bennett. Vol. 1: The Foundations of Natural Philosophy. Pp. xliii+534. (London: Hodder and Stoughton, Ltd., 1956.) 42*s*. net.

A. N. WHITEHEAD has said: "It is a safe rule to apply that, when a mathematical or philosophical author writes with a misty profundity, he is talking nonsense". Yet, in another place, this same mathematician–philosopher remarks: "Heaven knows what seeming nonsense may not to-morrow be demonstrated truth". Neither remark is to be taken too seriously, but both may be borne in mind when reading the book under review.

The sub-title of the present volume, the first of two, is "The Foundations of Natural Philosophy", but it must not be inferred that it is a book about physics. Mathematics, physics, and other sciences do indeed make their appearance, but the main concern of the work is to promulgate a highly speculative philosophical system, and the essential ingredients are metaphysics and mysticism. Mr. Bennett is a follower of G. Gurdjieff, a Caucasian Greek mystic, whose ideas have become widely known, principally through the activities of his disciple, P. D. Ouspensky. Gurdjieff, who died in 1949, wrote only one book, entitled "All and Everything", which bears superficial resemblances to Nietzsche's "Thus Spake Zarathustra" and to modern 'space-fiction'. In order to protect it from the idle scrutiny of iconoclasts, it was apparently a deliberate policy of Gurdjieff to make his book almost incomprehensible, so that its full significance, if any, could only be grasped after prolonged study. Mr. Bennett himself says: "After perhaps thirty careful readings, I still discover in it new depths of meaning". We do not know whether Mr. Bennett has adopted a similar plan for his own work but, by chance or design, he has achieved a similar end. Since this review is being written after only a single careful reading, perhaps I may be forgiven if some of the depths of meaning have not been revealed to me.

Eminent physicists have told us, as indeed lesser mortals have sometimes perceived, that the universe is mysterious. Contemplation of the universe, and even of some small part of it, often gives rise to mystic thoughts and emotions, which may or may not have a beneficial effect upon those who experience them. However, whether or not a physicist derives his inspiration from a mystical conception, and conducts his personal life by it, we feel that he should rigorously exclude it from his physics. Mr. Bennett evidently thinks otherwise.

As the basis of his physical theory Mr. Bennett postulates a six-dimensional Minkowskian geometry of the universe. The six dimensions are the four dimensions of space–time and, in addition, the 'dimensions' of 'eternity' and 'hyparxis'. It should be noted that the author uses an esoteric and ill-defined terminology which does nothing to further the understanding of his thesis. 'Eternity' is defined as 'the storehouse of potentialities' or 'the measure of intensity of being', and 'hyparxis' is defined as 'the condition of ableness-to-be'. Using arguments which are, to say the least, obscure, Mr. Bennett goes on to 'explain' certain known facts of elementary particle physics, that is, to fit them into his scheme. Of this I have only two things to say: first, a theory, not directly amenable to experiment, which confines itself to 'explaining' the bases of existing theories, without suggesting further developments, is a barren theory at most; and, second, the 'facts' of elementary particle physics are notoriously evanescent, so that the task of fitting them into a rigid universal scheme seems likely to be an unrewarding one.

Although the intricacies are such that it is difficult finally to assess this section of the work, I none the less believe that the theory has been erected upon an assumption which can most charitably be described as an unwarranted extrapolation. Mr. Bennett argues from the fact that kinetic and potential energy are interconvertible that they must be accorded the same existential status, that is, they must be supposed equally 'real'; and he goes on to say (p. 156): "Few people to-day doubt that energy exists and that 'visible matter' is only one of its manifestations. There need, therefore, be no hesitation in accepting the view that potential existence and actual existence are equivalent and interchangeable". In case the reader has any doubts about the meaning of this, I feel it necessary to quote at length a passage which occurs two or three pages earlier. Speaking of weather prediction, Mr. Bennett says: "We are not entitled to say that the fine weather that was still potential at ten o'clock but did not materialize is less real than the rain that is actually falling. The non-actualized fine weather is just as truly a part of experience as the actualized rain. For a different state of consciousness the sun might be shining at this very moment and the sky clear. I can, for example, think of sunshine, and perhaps, with practice, I could even voluntarily produce in myself all the sensations corresponding to sunshine, and thus, for my own experience, be able to actualize sunshine instead of rain. In yet another state of consciousness, two incompatible events might both be present simultaneously to my awareness".

In other places the mists draw aside to reveal a landscape even more bizarre. Mr. Bennett is, for example, a supporter of the biospheric hypothesis, according to which the biosphere, that is, the thin film at the surface of the Earth in which life exists, is a living entity higher in the scale of existence than man himself. Mankind may be regarded, so to speak, as the 'brain-cells of the biosphere'. In case this should be mistaken for mere poetic imagery, let me hasten to add that later in the book Mr. Bennett goes further and describes, not only the biosphere, but the Earth itself, as well as the other planets and the Sun, as beings of higher order than man. Number magic makes its appearance here, as elsewhere in the book—in particular, the magic significance of the number seven. "Every organized structure capable of independent existence has seven independent terms", we are told, and are not surprised to discover that there are seven 'true' planets—'true' planets being so defined that their number is precisely seven.

In his Preface, Mr. Bennett makes the disarming plea: "I can only hope that those who realize that we must, ***at all costs***, discover a means of looking at all that natural science has discovered in the last centuries ***as one coherent whole*** will be prepared to give the method a trial; and, if they are specialists in one or other of the subjects treated, will rather fill in the gaps and correct the errors than condemn the enterprise". (The phrases printed in italics are in bold type in Mr. Bennett's Preface.) I feel strongly that, if one of the costs is the abandonment of scientific method, it is too much to pay. None the less, I have read the book with much enjoyment and no little enlightenment. It should be read by all mathematicians and physicists—as a warning. S. RAIMES

HIGH ENERGY NUCLEAR PHYSICS

High Energy Nuclear Physics

Proceedings of the Sixth Annual Rochester Conference, April 3–7, 1956. Compiled and Edited by J. Ballam, V. L. Fitch, T. Fulton, K. Huang, R. R. Rau, and S. B. Treiman. Pp. xii + 368. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1956.) 3.75 dollars.

THE Rochester Conference on High Energy Nuclear Physics has been one of the important annual international events in the post-war scientific world. The hospitality of Rochester has been extended to delegates from all countries working in this field, and the 1956 Conference which is reported here was notable for the presence of Russian delegates for the first time.

The proceedings of the 1956 Conference arrived in Britain just as the 1957 Conference was taking place, so that already in this fast-moving field many further discoveries have already been reported. The 1956 Conference was particularly notable for the papers by Segre and others on the anti-nucleons, the production of which in the Berkeley bevatron had been discovered in the year previous.

Theory had predicted the existence of anti-protons long ago, and attempts had been made to find them in the cosmic radiation, and indeed some likely evidence had been found but without definite proof. The anti-protons were finally identified among the particles coming from a target bombarded by the 6 billion volt proton beam of the Berkeley Bevatron guided by magnetic fields. They travelled along a flight path of 80 ft. and were identified by their time of flight and the magnetic selector data combined with Čerenkov counter detection. Since then the annihilation process has been found and studied—up to 640 million volts being carried away by π-mesons. The large interaction cross-section of the anti-proton with nuclei was discussed by Teller.

Other important sessions of the Conference discussed the rapidly growing experimental evidence for the strange particles and their interpretation. The numerous modes of decay by the K-meson were described, and the evidence for the identical mass and life-time of the charged K-mesons was presented. This led to the theoretical discussion on the problem presented by the identity of the K-mesons, θ and τ, which decay into two and three π-mesons, respectively. The equality of life-time was said to be a 'miracle' not explained by theory. Later in the discussion, Feynman and Young considered the possibility that parity in weak interaction was not conserved—a hypothesis which has been abundantly confirmed during the past year.

There was also much interesting theoretical and experimental information on the interaction of nucleons and of π-mesons with nuclei.

The Conference has undoubtedly provided the best opportunity of keeping in touch with this fast-developing subject. In 1958 the Conference is to be held in Geneva.

J. D. Cockcroft

NEUROPHARMACOLOGY

Neuropharmacology

Transactions of the Second Conference on Neuropharmacology, Josiah Macy, Jr. Foundation, May 25, 26, and 27, 1955, Princeton, N.J. Edited by Prof. Harold A. Abramson. Pp. 328. (New York: Josiah Macy, Jr. Foundation, 1956.) 4.25 dollars.

Tranquilizing Drugs

A Symposium held under the auspices of the American Association for the Advancement of Science, in cooperation with the American Psychiatric Association and the American Physiological Society, and presented at the Atlanta, Georgia, Meeting, December 27–28, 1955. Arranged and edited by Harold E. Himwich. Pp. viii+197. (Washington, D.C.: American Association for the Advancement of Science; London: Bailey Bros. and Swinfen, Ltd., 1957.) 45s.

Hormones, Brain Function, and Behavior

Proceedings of a Conference on Neuroendocrinology, held at Arden House, Harriman, New York, 1956. Edited by Hudson Hoagland. Pp. xii+257. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1957.) 7 dollars.

The Pharmacology of Psychotomimetic and Psychotherapeutic Drugs

Conference held by the New York Academy of Sciences, Section of Biology, April 12, 13 and 14, 1956. Consulting Editor: Seymour S. Kety. (*Annals of the New York Academy of Sciences*, Vol. 66, Art. 3. Pp. 417–840. New York: New York Academy of Sciences, 1957.) n.p.

NEUROPHARMACOLOGY has enjoyed immense popularity, particularly in the United States, during the past years, and the number of conferences and symposia dealing with some aspect of the subject is legion. Transactions of four of these are reviewed here. As many participants read papers at several conferences, a great deal of overlap is inevitable, but there is a distinct character to each publication. The rapidity with which statements made at these conferences become out of date is a reflexion on the dynamic interest taken in the subject.

Earliest among the four conferences is the "Second Conference on Neuropharmacology", sponsored by the Josiah Macy, Jr. Foundation. It is written in the discussion style favoured by the sponsors, the speakers frequently being interrupted and the subject being treated as a discussion between members of the group. The main theme of the conference is the action of lysergic acid diethylamide (LSD) and its relation to human schizophrenia. There is also an amusing account of the origin of the work of Osmond and the Saskatchewan group on adrenochrome and adrenolutin as possible hallucinogens.

Next in chronological order is a symposium on "Tranquillizers", held in Atlanta in December 1955 and published in 1957. The first part deals with methods used for screening potentially useful drugs or to analyse their mode of action by physiological and biochemical methods. The second part brings the results of treatment of psychoses, the most important drugs being chlorpromazine and reserpine. Two new drugs, however, are just appearing on the horizon: azacyclonol (Frenquel) and meprobamate (Miltown). Reports on 6–8 months clinical use of these drugs, including double-blind trials, are presented from the Galesbury State Hospital and the Mississippi State Hospital.

The third conference was held in May 1956 at Columbia University's Arden House on the River Hudson. Its title, "Hormones, Brain Function, and Behavior", indicates that it is more concerned with the discovery of the causes of mental aberrations than with their treatment. Not nearly so much progress has been made in recent years on the interrelation of hormones and the nervous system as in neuropharmacology proper. Most of the book reports on the orthodox lines of investigations concerning the action of the adrenal gland, the gonads and the thyroid on behaviour and on metabolism of nervous tissue. One chapter, however, is devoted to the newly-aroused interest in 5-hydroxytryptamine (serotonin) as an agent controlling central nervous activity; it is interesting to see that this substance is classified as a hormone in spite of the fact that its occurrence in the brain is not related to the activity of any endocrine cells.

The latest report, covering a wide range of neuropharmacological topics, is that of the conference held in April 1956 at the New York Academy of Sciences. This is a most comprehensive and up-to-date survey of the actions and uses of the substances which formed the subject of the previous conferences. The actions of lysergic acid diethylamide and 5-hydroxytryptamine form a large proportion of the review, and much progress is reported in the analysis of the bio-electrical phenomena correlated with the action of these drugs, in the study of antagonists and in the understanding of the underlying biochemical events. Concerning the drugs used in therapy, progress has not only been made in determining their electrophysiological and biochemical actions, but also in observing the behavioural changes produced in animals and, most important, in using them judiciously in the therapy of psychoses. Indications for a particular drug or drug combination have become more precise, and there has been some success in the avoidance of crippling and undesirable side effects.

Marthe Vogt

SUPPLY OF SCIENTISTS AND TECHNOLOGISTS FOR INDUSTRY

THE report on "Industry and Technical Progress"* contains a key chapter on the supply of "Trained Men and Women", and a conference organized by the British Association was held to discuss this subject, under the chairmanship of Sir Henry Tizard, at the University of Leeds on July 5. In welcoming this well-attended Conference on behalf of the University, Prof. J. T. Whetton emphasized that the problem has many roots, some of which go deep into the schools and the social system. The additional recruits required for British industry cannot be produced like rabbits out of the additional hat now being provided by the expansion of facilities in the universities and technical colleges, and Prof. Whetton's concern about solving the equation of supply and facilities became a recurrent preoccupation throughout the day. Mr. R. J. Butler welcomed the Conference on behalf of the Leeds Chamber of Commerce, and asserted that cost-consciousness is not an inferior aspect of an engineer's work but a vital part of it, for which appropriate training should be given both before and after entry to industry.

Six main points were stressed by Prof. B. R. Williams (University College of North Staffordshire) in a brief introductory survey of the report, of which he is joint author. First, the use of science by industry is not simply a matter of buying a few scientists and providing a back room; rather it is essential to have the widest spread of scientifically minded people throughout the firm. Secondly, the complex chain of relationships between firms has been shown to have a powerful cumulative effect on productivity, or the lack of it. Linked with both these aspects, and of critical, indeed over-riding, importance is the quality of management. Where management is good, so generally is the use of science and technology in the firm. The total supply of technologists is extremely important, but the case studies have shown the critical lack of 'hybrids', that is, people who have mastered more than one discipline, be it mathematics and chemical engineering, physics and metallurgy, or engineering and economics. Finally, finance is not nearly so serious a problem as the shortage of scientists and technologists and the quality of management. We should know when we had solved this problem when finance once more became the limiting factor.

"Behind all the factors affecting our study stands the question of the supply of able minds—managers, scientists and technologists; and it will be seen that we are satisfied neither with the effectiveness of the British educational system in its work of selection of training, nor with the distribution of trained talent between industries and firms." With this quintessential quotation from the report, Sir Henry Tizard introduced its co-author, Prof. C. F. Carter (Belfast), who stressed two aspects of this question. First was the supply of first-rate ability, which is a question of nurturing what we have: secondly was the lack of training of various kinds, which may be dealt with by official policy. Prof. Carter indicated possible lines of action which the Conference might consider; for example: that employment advisory services for young people should operate in grammar schools before the crucial age of specialization and not at the time of leaving school; that allowances, subject to a means test, should be given to children remaining at school after the age of fifteen; specialized university entrance should be greatly relaxed; that consideration be given to a two-tier system of university degrees in science; that more research be undertaken into the teaching of mathematics, and into the elimination of much drawing-office work, and by the professional institutions into the efficient use of scientific and technical staff in industry.

With Sir Ben Lockspeiser in the chair, the second morning session began with Sir Alexander Fleck stressing industry's responsibility as a provider of scientists, as well as in receiving them and using them properly afterwards. In both respects, however, he was concerned with wider education conducive to good personal qualities and powers of leadership. There is urgent need to achieve a new balance between science and the arts, and Sir Alexander commended both the courses at the University College of North Staffordshire and the new proposals at Cambridge. Careful examination should be made of the use of scientists in industry, but there is a proper place for them on the sales side, especially on the way to top management, and this is not fairly described as 'edging nearer the till'. In Imperial Chemical Industries, one in four are engaged on research and development; for the other three a high degree of technical efficiency is desirable, but personal qualities vital in teamwork and leadership are at least as important. Education and training must take account of these trends, which are bound to continue, and science could no longer be regarded as an optional extra to traditional subjects. The education of the scientist must prepare him to take a full part in the management of industry.

The worst shortage in the atomic energy industry, that of design engineers, was discussed by Sir Christopher Hinton. There is no general agreement as to the training of engineers, because it is inherently more of an art than a science, and this art can be learnt only by practical experience in industry. For this reason, though some expansion was justified, a large expansion of university engineering schools would be a serious mistake. More should come through the technical college route, with early industrial experience to get the real feel of engineering, and with concurrent or closely related theoretical study. Sir Christopher illustrated this by reference to the design office establishment of the Atomic Energy Authority at Risley. Of 158 professional staff only fifty-three have degrees, and some of these were external degrees taken part-time through the technical colleges. The remainder had come via the part-time day- and evening-class route alongside industrial experience. Of 226 at the assistant designer grade, only seventeen have degrees, but this 226 forms the main source for supplying the professional grade. There are 286 in the drawing office grades and none has a degree, but they are very good design staff. This was the total establishment which had been responsible for the solution of major engineering problems in the atomic energy developments. Conversely, of ninety experimental officer grades, forty-seven had degrees, but the posts needed only the General Certificate of Education at advanced-level in two subjects. Sir Christopher was very concerned about the consequent waste of university places in a period of great shortage. At the same time, he was equally concerned about what industry did to graduates after entering employment. After ten years employment, British graduates too often compare unfavourably with those in United States industry in vigour and initiative.

---

* Industry and Technical Progress: Factors Governing the Speed of Application of Science. By Prof. C. F. Carter and Prof. B. R. Williams. Pp. viii+244. (London and New York: Oxford University Press, 1957.) 25s. net. (See also p. 301 of this issue of *Nature*.)

The wider education and effective training of graduates in industry was then examined by Guy Hunter, deputizing for Sir Reginald Verdon-Smith (Bristol Aeroplane Co., Ltd.). These are essential both for good management of industry and the general well-being of the nation; the latter especially, since such graduates increasingly occupy key positions, and will greatly influence the transmitting of the national tradition of moral, social, political and cultural values, and will also lay the foundation for the much greater weight of technology needed to sustain modern society. Industry should organize two-year postgraduate training as continued education as well as industrial training, preferably on a sandwich basis, with the universities, advanced technical colleges and industry itself supplying the varied advanced teaching required.

The afternoon session under the chairmanship of P. A. Macrory (Unilever) was devoted to the concern of the schools, colleges and universities with the supply of scientists and technologists. Dr. A. D. I. Nicol (University of Cambridge Appointments Board) was concerned with the unpredictable nature of State scholarship and open scholarship results. For example, of the State scholarship students of mathematics at Cambridge, 70 per cent had obtained only third-class honours degrees. More pass and general honours degree courses might be run for those who aim at technical careers apart from research, but the able scholars should not be sacrificed to these requirements. For them a four-year course or more postgraduate courses are now essential. In the schools a taste for advanced mathematics must be more widely cultivated, since it is the universal language of modern science, and all understanding is limited if some mastery is not attained in it.

As he had first-hand knowledge of it in his local education authority area, A. B. Clegg (chief education officer, West Riding of Yorkshire) was concerned with the problem as to why only 6 per cent of the children of unskilled workers capable of doing sixth-form work actually remain at school, as against 44 per cent of the children coming from professional and managerial classes. He examined the cumulative effects of two main causes, lack of parental ambition and the educational handicaps of the social background of many of the children of unskilled workers, and considered that the role of the school, in offsetting these serious drawbacks, should be to provide a broader education and background to literacy, and to develop wider interests and easy social relationships. But all this is increasingly limited by specialization, rising examination standards, and especially by the impact of the open scholarship system of Oxford and Cambridge. It bears most severely on the socially handicapped able child, in a school likewise handicapped. Unless this difficult matter is dealt with, it may become as highly charged politically as the 'eleven-plus' test has become since the Second World War, and it may well invite increased government probing into university affairs. With suitable safeguards, some experiments should be made in allowing such schools to nominate their own university entrants, when the errors are unlikely to exceed the 17 per cent or so now typical of local authority awards.

From the angle of technical education, Dr. P. F. R. Venables (Birmingham College of Technology) found some encouraging trends since the White Paper was published. A new structure is emerging, more allied to the needs of industry: local and area colleges concerned with courses for technicians and craftsmen, some eighteen regional colleges (rising possibly to thirty) concerned with advanced courses for the foregoing and a limited number of courses for technologists; and the eight (probably ten) colleges of advanced technology concerned solely with training scientists and technologists. Part-time day release enrolments have already increased by about 8 per cent, City and Guilds examination results by 13 per cent; full-time advanced courses have risen by 9 per cent, and similar part-time day courses by 4 per cent. Sandwich courses had an intake of some 1,200 as compared with an output of about 500 the previous session. Of 173 sandwich courses which have now been started, twenty-five have been recognized by the Hives Council for the new diploma in technology (in addition there are six full-time courses so recognized). Qualitative problems noted in the report under discussion are being met by the introduction of industrial administration, economics and related subjects, and of liberal studies, into all undergraduate courses. Nevertheless, there remains serious cause for concern in the wastage of ability in part-time courses, the lack of women students, insufficient training after entry into industry and, above all, the continuing critical shortage of highly qualified teaching staff.

Coming at the end of the various papers and earlier discussion, C. H. Wilson (University of Leicester) tried to put some points in perspective. Too many mutually contradictory arguments had been used; for example, that standards should be raised in the universities, while they should admit many more by lowering faculty requirements and abolishing the scholarship system. There was also a complete lack of reality in piling ever more tasks on to the universities: the quinquennial grants had been fixed, and therefore their potential work was already limited, and additional suggestions must remain pipe dreams. Mr. Wilson cited as evidence of loss of ability the fact that of those leaving the public schools at seventeen and eighteen years of age, only 44 per cent went on to university and other advanced education, and the figure for maintained grammar schools was 41 per cent. The perseverance for science and mathematics courses was greater, the respective figures being 81 per cent for public schools and 50 per cent for maintained grammar schools. Numbers should be increased without lowering standards, by rescuing the general degree from the neglect into which it has fallen; but industry must first make up its mind as to what proportion of specialists (honours degree men) it wants in comparison to those whose future occupations require a good general science training.

The task of summing up the contributions of thirteen speakers and twenty-four participants in the discussion was allotted to Sir Henry Tizard, but he wisely preferred to round off the conference by stressing only a few salient points. If the supply of scientists and technologists who will remain as such is doubled, it will probably be adequate; but a very much greater increase is required in the number of scientifically educated people for industry, and indeed all walks of life. Specialization has no evils for the able man, and the university and advanced college are appropriate places for this specialization. Not so for the remainder, and greater care must be taken to secure a wider education for them. Everyone agrees that the British educational system is not meeting modern needs, but there has been substantial progress in the schools, colleges and universities. In his day at Westminster School, Sir Henry said that only one other boy was studying science; now the yearly increase is 10 per cent and the science sixth will soon equal the rest. Technical education is progressing rapidly in quality and quantity, and should be given far more money for its needs. A comparative survey of the systems of all the western-European countries is urgently needed. Though universities are complaining, Sir Henry said that he knew of no other European government which makes a recurrent grant equal to £31 million per annum to universities. How do those universities manage? And what light would such a survey throw on British university organization? Far more trust is needed between the universities and the schools in Britain, and one of the younger universities should take the initiative in making closer direct examination and nomination arrangements with selected schools. A pilot experiment, conducted some years ago at the Imperial College of Science and Technology, London, had improved relationships and the number of first-class people coming forward.

Well organized as the conference was, it had too crowded an agenda, with an almost breathless succession of speakers and participants. An opportunity was lost in not spreading the same programme over two days, with far more ample opportunity for discussion, and particularly for members to question the authors more closely upon many aspects of their valuable report.

P. F. R. Venables

CAPITAL FOR SCIENTIFIC DEVELOPMENT

The conference on "Capital for Scientific Development" at the Royal Society of Arts on June 27 was the earlier of two conferences arising out of the inquiry conducted by the Science and Industry Committee of the Royal Society of Arts, the British Association and the Nuffield Foundation into the possibility of speeding up the application to industry of the results of scientific research. The other conference, on the supply of scientists and technologists for industry, is surveyed in the preceding article. In opening the conference the President of the Board of Trade, Sir David Eccles, suggested that the weakness of British industry lies in failure to pay enough attention to the cost of applying new processes and machines, and that the value of Profs. Carter and Williams's book lies in stimulating thought about industry and technical change, and in challenging generalizations too broad to be true. Sir David agreed that company taxation might be less of a deterrent than some people think, but said that it mattered what they thought and that the answer depends on whether, assuming any rate of taxation, the public sector would leave the private sector enough savings.

The subject was dealt with in two sessions devoted respectively to large and small firms, but the discussion was preceded by a short account of the survey by Prof. C. F. Carter, who summarized its findings on this point. At the time of the survey many firms were certainly not held back by lack of finance, although they might be described as stagnant pools. Others, including some highly progressive from a technical point of view, had their development limited by the difficulty of retaining enough money in a period of high taxation, or by their inability or unwillingness to raise money from outside. Prof. Carter suggested that the problem, in its broadest terms, was whether the supply of savings was as high as it could reasonably be made, and whether our financial machinery was such that these savings were available to the investment borrowers with the best claim. These questions raised very wide issues, some of which, including the place of the National Research Development Corporation in the financial support of key developments, Prof. Carter indicated.

The discussion on the position of the large firm was opened by Lord Dudley Gordon, who thought that new capital was normally required to develop the results of research in an existing department, and he found it hard to accept the suggestion in the report that a board of directors might refrain from increasing a dividend so that it may have funds to erect a new factory. Lord Dudley observed that surpluses shown are not usually available as cash, and new development resulting from research has to be paid for in cash. Large sums have also to be found for maintenance and repairs and to comply with the provisions of such measures as the Clean Air Act, and nearly every major project involves raising additional capital in some form, rather than cash from internal resources.

Sir Nutcombe Hume, who opened the discussion on the smaller firm, said that the conclusions drawn by Profs. Carter and Williams on capital for development accorded with those reached by the Charterhouse group of companies, of which Sir Nutcombe Hume is chairman, as a result of their experience in this field. Sir Nutcombe thought there were all too many men in responsible managerial positions, especially in the smaller companies, who did not know the extent of the facilities available and their uses. An essential ingredient of good management was the realization that, at least in matters of finance, a company must choose some reputable finance house and trust it to do what is best for the company. He also pointed out that the minimum size for a company to prove attractive to the Stock Exchange and investors seeking a free market in the securities they hold had been growing for many years, and he did not think that the report distinguished strongly enough between capital in the form of borrowed money and that in the form of share capital. It was thoroughly bad that the incidence of profits tax should favour borrowing money and put such a heavy burden on ordinary share dividends, but he agreed with the authors of the report that too much time and energy were occupied by the problem of death duties.

Apart from this, few of the issues specifically indicated by Prof. Carter were mentioned by the other speakers, though Prof. Carter did not suggest that they would necessarily be discussed. Some of these points may be mentioned in conclusion to indicate that something more was done at the conference than to ventilate a pressing problem of modern industrial development and to seek possible solutions. There is the question whether there is a right balance between compulsory and voluntary saving; is it good or bad for technical progress that so much capital investment should be financed from ploughed-back profits; are the inducements and privileges given to private savers sufficient, or could a useful increase in private saving be obtained by further inducement? Again, are selective means of encouraging specially productive industries needed and can we make better use of men with ideas but no great ability in finance or sales? What is the place of general measures such as the investment allowance and do frequent changes diminish their efficacy? Is there any better way of controlling fund-raising from the markets than the present Capital Issues Committee, or would it be better for technical progress if capital were rationed by prices? Is there any better way of ensuring finance for small companies which unite technical progressiveness with business competence, and can anything be done to allay the fears of small firms which inhibit them in seeking outside finance?

SMOKING AND LUNG CANCER

REPORT OF THE TOBACCO MANUFACTURERS' STANDING COMMITTEE

THE tobacco manufacturers of Great Britain, disturbed by the reports that the evidence for a close relation between smoking and lung cancer was piling up, gave in 1954 a fund of £250,000 to the Medical Research Council for furthering research on the subject. Not satisfied with the results of their philanthropy, the manufacturers are now about to set up a new fund for research to the tune of £1 million. Their Standing Committee consists of technical representation from the different companies, and a scientific consultants panel of two eminent scientists, namely, a chemical technologist and a statistician-geneticist.

The report, issued by the Standing Committee (6–10 Bruton Street, London, W.1), dated June 17, 1957, shows undisguised attempts to belittle the findings of those investigators who have shown a correlation between smoking and lung cancer. For example, it points out that one's daily intake of benzpyrene in the air in a West Country town is equivalent to the benzpyrene content of the smoke from forty cigarettes and the daily intake in London to the benzpyrene from one hundred cigarettes. These statements could imply that the best-known carcinogen (benzpyrene) present in cigarette smoke can be ignored as a factor in the lung cancer–smoking relation, since the air already contains more benzpyrene than the amount to which the great majority of smokers are exposed. Unfortunately for this idea, the lung cancer rate has been rising rapidly in many places all over the world and including towns in Norway, Iceland and Denmark, where the air is far less smoky than in English towns and where, as a consequence, the benzpyrene content of the air is a small fraction of the English figures. Moreover, women have a much lower lung cancer rate than men, although they breathe the same air.

Nevertheless, the laboratory work of the Committee is largely concerned with the measurement and the formation of benzpyrene in cigarette smoke. The report records that the arsenic content of cigarettes is declining due to alterations in the pest-control technique on the tobacco crop. However, the implication that arsenic in the smoke could be the responsible carcinogen is undermined by the available lung-cancer figures for Turkey, where the disease is about as common as in other European countries, but where the tobacco contains scarcely any detectable arsenic.

Although the report begins by rejecting the lung cancer–cigarette relation, its laboratory work energetically pursues the theme that cigarette smoke contains carcinogens such as benzpyrene, arsenic, dibenzanthracene, or some as yet unknown carcinogen lurking among the other constituents of cigarette smoke, which are identifiable or have still to be defined.

The report brings its heavy guns to bear on the statistical aspect of the problem. It emphasizes that a contingent statistical relation does not guarantee causation. Let us take an example of what could be called contingent. Seaside-sunburn in London school children, before the motor-car, was always preceded by a railway journey. The railway journey is contingent to the sunburn but is not the cause of the sunburn. To take a strictly practical point of view, the seaside-sunburn could have been avoided by shutting down the railways, and in the same way lung cancer could be largely avoided by closing the cigarette factories, quite independently of whether lung cancer and smoking have a causal *or* a contingent relationship.

The report refers to the 'genetic factor', that is, a hypothetical factor present in part of the population which determines not only susceptibility to lung-cancer but also a disposition to seek tobacco. Then why did not this genetic trait show itself before the lung cancer epidemic got under way, at about 1910–20?

A further theme pursued in the report is the alleged imperfect randomness of the patients who were the subjects of the Doll–Hill investigation. Surely, non-randomness is what is required: to choose parallel lung-cancer and non-lung-cancer patients for comparison whose other differences have been cancelled out with the exception of one variable, namely, smoking or non-smoking. This Doll and Hill did: they studied 1,357 men who had contracted lung cancer and the same number of men free of lung cancer as controls, together with 108 women suffering from lung cancer and 108 women controls. The patients and their controls were in the same hospitals in London, Birmingham, Cambridge, Leeds and Newcastle and in rural areas of Dorset and Wiltshire; they belonged to the same age group, had been in hospital for the same length of time, and the controls even had the same disease (cancer) of some other part of the body. It would be difficult to imagine a more carefully worked out scheme of matched controls. The results of the Doll–Hill investigation are now too well known to need reiteration.

The report develops the argument that modern therapeutic methods have allowed age groups liable to lung cancer to survive which would previously have had large losses by death at a less advanced age. Let us then assume that the steep fall in the tuberculosis death-rate since the latter part of the past century has saved susceptible groups for a later death from lung cancer. But what of the women? Their death-rate from lung cancer is much below that of the men. It will be necessary then to postulate a second hypothesis, that lung cancer is sex-linked. But our difficulties are not over, for the lung-cancer rate for women has been rising quite rapidly. For the moment, this line of argument is better abandoned.

I. HIEGER

THE NATIONAL COAL BOARD'S PNEUMOCONIOSIS FIELD RESEARCH

By Dr. J. W. J. FAY

Chief Scientist of the Research

PNEUMOCONIOSIS is a condition which starts almost imperceptibly with the fixation of a small amount of dust in the lung, and as the period of exposure increases more and more dust is accumulated. So long as the condition remains as 'simple' pneumoconiosis, it is believed that it will not progress if the subject is removed from the dusty environment, and disability is absent or comparatively slight. The rarer but more serious form is known as 'complicated' pneumoconiosis, or progressive massive fibrosis. In this form of the disease the patient's condition deteriorates even if he is removed from the dusty environment. Progressive massive fibrosis is thought to be caused by the superposition of an extraneous infection, probably tubercular, on a background of simple pneumoconiosis usually in its more advanced stages. Hence, if pneumoconiosis is halted at the earlier stages of the simple form, the results are not serious. Both forms of the condition are recognizable by X-ray examination of the lungs.

In spite of the work which has already been done, pneumoconiosis still presents a serious problem in the coal-mining industry, about five thousand new cases being certified every year. The National Coal Board has therefore undertaken a field research to study the effect of the dust breathed by coal-miners in the course of their work. As the result of long-term field studies it is hoped to obtain accurate data on which to base safe levels of dust concentrations which miners will be able to tolerate throughout their working lives without suffering any considerable disability.

The research, which was started in 1953, is being conducted at twenty-five collieries in England, Scotland and Wales. The selection of collieries is designed to provide a reasonable cross-section of mining practices, conditions and types of dust, in order to investigate the effect of composition as well as quantity of dust. These twenty-five collieries employ about 35,000 men, approximately 5 per cent of the coal-miners in the United Kingdom.

Medical Studies

There are two mobile medical units, each equipped with the most up-to-date X-ray machines for taking full-size chest X-rays of the population at each colliery every three years or so. Each unit is in charge of a senior medical officer and includes a qualified physiologist, a radiographer and clerks, technicians and ancillary staff to a total complement of nine.

The films are classified into categories of pneumoconiosis according to the international (I.L.O.) classification, which recognizes four stages of simple pneumoconiosis and four of progressive massive fibrosis.

The reading of the films is done by the senior medical officers. Due precautions are taken to estimate the accuracy and consistency, including the application of cross-checks and a continuous statistical control on the reading levels. By this means a uniform and satisfactory standard of reading is maintained.

The first round of X-ray surveys has been completed, and the results have shown a wide range of prevalence of significant pneumoconiosis at the different collieries.

At the time of the X-ray survey, details have been recorded of the past working histories of all the men examined. There is thus available a record of the prevalence of pneumoconiosis on an individual basis among the present populations at the collieries, together with a record of the environmental history which has contributed to the prevalence revealed. This information enables an estimate of the prevalence throughout the coalfields to be made.

The examination is voluntary, but the co-operation of the men has been extremely good, the overall response being about 95 per cent. The lapses have been analysed in terms of age and occupation and they do not appear to be significant in either respect. Thus the population examined is considered to be representative of all the men working at the collieries at the time of the surveys.

The second round of medical surveys will be started this year, and a number of simple anthropometric and physiological measurements will be made in addition to the X-ray examinations. This is in order to investigate the relationship between X-ray classification and disability. In addition to the physiological tests, which are primarily intended to investigate respiratory function, a questionnaire will be used for eliciting information regarding other chest conditions which may complicate the investigation of pneumoconiosis.

Environmental Measurements

The environmental sampling programmes are designed to measure the environments of the men, particularly dust concentrations, for the purpose of correlating the attack and progression of pneumoconiosis as revealed by the follow-up X-ray surveys with the intervening dust exposure which has caused it.

An individual record of dust exposure is required for each man under observation, to match against his X-ray record. The system adopted to accumulate the necessary data has been to stratify into occupational groups the population of each colliery and to get a measure of the environment of each group. Each occupational group consists of men doing the same work, at the same time, in the same place, so that the environment within any one group can be expected to be reasonably uniform. The sampling procedure is to select representatives randomly by name from each of the groups and to measure their exposure throughout a working shift. Different representatives are covered on successive shifts of sampling and, by a suitable choice of sampling fractions, occupational group exposure indices are built up with increasing accuracy as time goes on. These occupational group exposure indices are attributed to each man in the group for the period he spent in the group, and in this way an individual exposure index is cumulatively recorded for each man under observation.

The dust concentrations are measured by investigators based at the collieries who accompany the representatives throughout their working shift. The thermal precipitator is used as the standard instrument, and the dust concentrations are evaluated in terms of the 1–5 micron particle counts, as representing the best practical method of assessing the respirable dust. There are sixteen senior investigators (scientists) engaged in these field studies, each being responsible for the work at one or two collieries. They are assisted by thirty-nine junior investigators (scientific technical officers), giving a total field team of fifty-five, an average of just over two investigators at each colliery. The actual distribution of staff depends upon the size of the colliery. The environment of the whole colliery population is measured, and a picture is built up of the dust exposures of all the occupational groups on all shifts.

The sampling procedures are standardized and the performance of the investigators in evaluating their samples is subject to continuous check. In this way satisfactory counting levels have been attained and maintained by the team as a whole throughout the investigation.

The success of the system of sampling by occupational groups depends upon maintaining an accurate record of each man's working history. At any one time there are about 1,400 occupational groups altogether, with considerable movement of men from one group to another. Records must therefore be kept of changes in occupation, and the methods for doing this have been successively refined as the investigation has proceeded. The system which has finally been developed involves the use of individual mark-sense Hollerith cards which are prepared by a clerk at each colliery. The cards are mechanically punched, sorted and summarized on a Hollerith machine at headquarters in London to provide a detailed record of environmental exposure, due allowance being made for the man's time at risk.

The emphasis so far has been on the measurement of dust concentrations in terms of total particles of respirable dust, but the question of composition is covered in two ways. The thermal precipitator slides are evaluated regularly in terms of coal and non-coal particles in order to record what proportion of the 1–5 micron dust is mineral. In addition, work has been started on the collection of gravimetric samples of the various dusts for composition analysis, inuding an estimate of the free silica content.

Correlation of the Medical and Environmental Data

The ultimate object is to correlate the observed progression of pneumoconiosis with measured dust exposure. In the first place, the hypothesis to be tested will be that radiological pneumoconiosis is related to dust exposure expressed in terms of the number of 1–5 micron particles per unit volume of air. Alternative hypotheses will have to be investigated if this simple hypothesis is disproved. For example, it may be necessary to take account of the composition and size distribution of the dusts, as well as to investigate the effect of very high intermittent, or 'peak', concentrations. It is, however, impossible to undertake any analysis based solely on the observed progression and measured dust concentrations until at least one follow-up X-ray survey has been made and some progression measured.

Hence the analysis is limited for the time being to an examination of the present prevalence in terms of past occupations. The past working histories taken during the first X-ray surveys have been summarized and analysed in terms of prevalence of pneumoconiosis and period of exposure in the different occupations and places of work. In this way it is possible to obtain information about the relative hazards of different occupations at the various collieries in the past, which will provide a useful background of knowledge for the quantitative correlations later in the investigation.

The planning and supervision of the environmental sampling programmes and of the medical/environmental correlations, as well as the development of new techniques and methods of analysis, are carried out by a headquarters unit consisting of eighteen scientists and technologists and twenty-four clerical and ancillary staff—a total complement of forty-two. With the eighteen people associated with the medical units and the fifty-five investigators in the field, there are thus 115 people engaged full time on the investigation.

The investigation is still in its comparatively early stages and much of the effort to date has inevitably been devoted to the design and application of the long-term procedures. This account has therefore been largely limited to a description of the background and planning of the investigation. The results so far available are preliminary ones, but those which are of general interest will be published from time to time.

It is impossible to acknowledge in detail the help and encouragement which are forthcoming from so many people. Without this co-operation, however, it would obviously be impossible to conduct the investigation, which can safely be said to represent a good example of a large-scale, co-operative experiment in the field of occupational hygiene.

This short statement of the programme of research is published by permission of the National Coal Board.

NUCLEAR RADIATION MEASUREMENTS DURING THE INTERNATIONAL GEOPHYSICAL YEAR

By Dr. BERT BOLIN
International Meteorological Institute, Stockholm

THE development in the field of nuclear physics in recent years has indeed been remarkable. Not only has our understanding of the principles of nuclear reactions been vastly increased, but refined techniques for identifying and measuring radioactive isotopes in exceedingly small amounts have also been developed. These latter methods have been of great use in biological and medical studies; of late they have been applied to geochemistry, and are now finding their way into geophysics. A new and powerful tool for studies of our environment has thus been placed at the disposal of the Earth scientists, the ultimate possibilities of which we cannot judge to-day. It is highly desirable that the great promise of this field be realized and a global observational programme formulated, particularly in view of the intimate world-wide co-operation in all fields of geophysics during the International Geophysical Year 1957–58.

A number of natural radioactive elements are found in Nature, the existence of which has told us interesting facts about, for example, the history of the Earth, the exchange processes in the atmosphere and the sea as well as through the interfaces between these media. Thus determinations of beryllium-10 in deep-sea sediments may be of importance for studying the chronology of the bottom floor; the distribution of the much more rapidly decaying isotope beryllium-7 might yield interesting information about the horizontal large-scale mixing in the atmosphere. Determinations of carbon-14 in the sea and atmosphere have given much more precise knowledge about the exchange of carbon dioxide between the atmosphere and the ocean, and may very likely tell us something about the speed of circulation of the deep ocean. Similarly, studies of the radium and ionium content of the deep sea throw some light on the water motions in the bottom strata of the deep sea. A number of investigations of radium and thorium and their daughter products have given us better knowledge of exchange processes in the surface layers of the atmosphere.

In the past twelve years an increasing number of radioactive elements have been introduced into the atmosphere through nuclear weapon tests. In a thermo-nuclear explosion more than one hundred different radioactive isotopes are formed directly or indirectly. Most of these isotopes were previously not present in measurable amounts in Nature, while in other cases this new source means a contamination of the natural reservoirs of radioactive elements. Thus the amount of tritium in the atmosphere, sea and lake waters has significantly changed due to these experiments. It may, therefore, now be difficult to determine precisely the amount of tritium on the Earth that is of natural origin. On the other hand, the variable input of tritium by man into the atmosphere, and its propagation in the water-cycle, will probably yield interesting information about this cycle itself, that might have been difficult to find using only the naturally formed tritium. Other radioactive isotopes produced by nuclear weapon tests are strontium-90 and caesium-137, the distribution of which has already revised our ideas about the vertical exchange in the stratosphere, and most likely will be of great importance for the study of the general circulation of the atmosphere.

Already measurements of the total amounts of man-made radioactivity deposited on the ground have shown remarkable variations. Meteorologists might earlier have thought of the motion of the atmosphere as a large-scale turbulent process, but observations of the radioactivity of the air reveal details that would have been very difficult to obtain by any other method.

In view of the large observational programme in all fields of geophysics during the International Geophysical Year 1957–58 it seems highly desirable also to organize a programme for observations of radioactive elements in Nature. Quite a large observational network for measuring the radioactivity of the air and the deposited radioactivity has been reported to the United Nations, but the question of health hazard has been the main objective in the organization of these observations. It seems that the purely geophysical and geochemical aspects of the problem deserve a much more detailed examination. Recognizing this the Special Committee for the International Geophysical Year (CSAGI) in September 1956 endorsed a recommendation that a programme be formulated for measuring, on a world-wide basis, the nuclear radiation of air and precipitation and of solid particles deposited on the ground. Based on this recommendation a Working Group on Nuclear Radiation met at Utrecht during January 22–26.

The programme adopted by the Special Committee for the International Geophysical Year should be looked upon as a minimum programme. In view of the short time available for preparations before the beginning of the International Geophysical Year it was felt most important to start a basic programme which might then gradually be expanded. It is quite clear that most of the observations suggested should continue after the end of the International Geophysical Year, and therefore observations starting during the Geophysical Year would be of great value to future work in this field. Furthermore an Advisory Committee on Nuclear Radiation has been appointed to co-ordinate these efforts. This may be even more necessary here than in other disciplines, partly because of the short time still available for preparations, and partly because the programme covers a number of different fields in geophysics, such as cosmic radiation, meteorology, oceanography and glaciology. The chairman of the Advisory Committee is Dr. W. Bleeker, of the Royal Netherlands Meteorological Institute, de Bilt. It was also considered important to keep in close contact with the United Nations Special Committee and the World Meteorological Organization on this subject.

Essentially four observational programmes were outlined in the recommendations from Utrecht.

Measurements at ground-level of: (*a*) particulate airborne fission products; (*b*) the deposition of fission products in precipitation and as dry deposits; (*c*) the natural radioactivity of the air.

In the first place the programme aims at measurements of the total activity of air and precipitation, which would be of considerable interest, for example, as identifiers of air-masses. Where technical facilities exist for more detailed analyses of the samples the following isotopes were considered as of particular interest to the geophysicist, namely, strontium-89 and 90, cæsium-137, bismuth-210 and polonium-210.

Observations of radioactivity of the air in the free atmosphere. It is clearly realized that one can scarcely expect a fully world-wide network to be established for the International Geophysical Year. A knowledge of the distribution of the radioactivity in the free atmosphere is, however, of fundamental importance for a correct interpretation of the fall-out pattern at ground-level. Even a small number of additional measurements would be of great value in this respect, and would thus supplement the programme of measurements at ground-level. Furthermore one may hope to achieve a more complete network at an earlier date by extending international collaboration at the present stage.

Measurements of the tritium content of water before nuclear weapon detonations, for determination of the natural distribution of tritium. The water cycle in Nature is of great interest from many points of view. Tritium offers an excellent possibility for studying this cycle in more detail. In particular the speed of circulation within and between the different reservoirs may be determined. The natural distribution of tritium is poorly known, since nuclear weapon tests have thrown considerable amounts of tritium into the atmosphere. It should be possible, however, to establish the 'pre-atomic' tritium distribution by analysing glacier ice which has not been contaminated by melting. In middle latitudes wine bottled before 1945 should yield representative figures.

Determination of carbon-14 and tritium in the oceans at the surface and if possible at greater depths. Interesting results have recently been obtained about the circulation of the ocean and the exchange between the ocean and the atmosphere of carbon dioxide and water. These results are based upon very few measurements, and it is doubtful if these are truly representative. A world-wide programme for such measurements would be of very great interest both to oceanographers and meteorologists.

Some of the scientists actively engaged in applying these new techniques to geophysical problems may regard the programme outlined above as too limited. It may, nevertheless, be difficult to achieve even this modest goal during the International Geophysical Year. It is therefore necessary to look upon this programme as a first attempt to arrive at international co-operation among geophysicists in the field of nuclear radiation. Geophysicists would profit greatly from such a development. Equally important, however, is the recognition of the fact that geophysicists are needed for the best utilization and interpretation of the nuclear radiation data that until now have been collected essentially by physicists. We should be looking forward not only to international co-operation but also to interscientific co-operation.

OBITUARY

Lord Clinton, P.C., G.C.V.O.

THE age of the great landlords of Britain is passing. Heavy taxation limits their activities during life, and death duties break up their estates after they die. But the countryside, agriculture and forestry owe much to these men for their devotion to their estates and their work to improve methods of farming and management of woods.

Lord Clinton, who died recently in his ninety-fifth year, was one who contributed much. It is true that he does not leave behind him a name such as "Turnip" Townshend or Coke of Norfolk, or possibly even that of his friend and colleague Sir John Stirling Maxwell, who introduced modern methods of tree planting. But he was a great landowner owning very large properties in Devon and with estates in Scotland. He devoted his life to the management of those estates, and, except for an interlude when he served with the Devon Yeomanry during the First World War, all his activities were concerned with the land he loved and understood so well.

His personal interest in his estates was such that in effect he managed them himself, extensive though they were. But forestry was probably his greatest interest in land use, and at a time when there was no great encouragement to private forestry he managed his extensive woodlands in the light of the most modern knowledge at the time. His personal interest may perhaps best be shown by the fact that whenever possible he made a practice of marking his own thinnings.

For a short while after the First World War he was Parliamentary Secretary to the Ministry of Agriculture. But with the passing of the Forestry

Act in 1919 which set up the Forestry Commission, he was an obvious choice as a member of the new body, joining his friends Lord Lovat and Sir John Stirling Maxwell. Starting a new venture like this was a landmark in forestry history, and foresters throughout Britain owe much to the hard and difficult work which these pioneers carried out. To all this Clinton contributed greatly, not only from his knowledge of forestry, but also from his experience in public affairs both local and national. From these efforts has risen an organization which those pioneers can scarcely have imagined.

He remained a member of the Forestry Commission until 1930, becoming chairman in 1927. His interest in forestry persisted to the end, and as recently as 1956 he persuaded the Forestry Commission to take over his woods on his New Pitsligo estate in Aberdeenshire to ensure that neither the effects of good management nor his experimental work there should be lost in the future.

Clinton was Lord Warden of the Stannaries in the Duchy of Cornwall during 1922–33, and to this office he was able to bring his great experience of land management. This office means in effect that he was the principal adviser to the heir of the throne in the management of his estates. It is, however, curious that in that office he never succeeded in arousing much interest in forestry in the Duchy woodlands.

He was also chairman of the Lawes Agricultural Trust Committee, the governing body of Rothamsted Experimental Station, during 1924–37. Here again his profound practical knowledge of agriculture and its needs was of great value to a body of scientists who, in common with scientific endeavour in almost all walks of life, had a tendency to be led astray from any practical aspects by their enthusiasm for theory.

During his very active life, Clinton was able once again to show how much Britain is losing by the passing of great landowners such as he. RADNOR

NEWS and VIEWS

Meteorology at Harvard :

Prof. Charles F. Brooks

DR. CHARLES F. BROOKS, professor of meteorology at Harvard and director of the Blue Hill Observatory since 1931, is retiring this month and will be succeeded by Dr. R. M. Goody, at present reader in meteorology in the University of London (Imperial College of Science and Technology). Dr. Brooks, who was born in 1891, is perhaps the best loved figure in present-day American meteorology. He is noted for his integrity, courage and helpfulness to others, and these qualities have been most apparent and appreciated in his work for learned societies. In 1919 he set about re-establishing the American Meteorological Society (a task in which others had previously failed), became its first secretary and later treasurer, and by his personal efforts helped greatly to make it the successful institution which it is to-day. He held the post as secretary continuously until 1953. He has also served as president of the American Geophysical Union. Dr. Brooks is a meteorologist of infectious enthusiasm, occupying himself with observations when travelling on business or pleasure. His research work has covered the wide range of the climatology of North America, long-range weather forecasting and the effect of ocean temperatures on weather, instruments, microclimatology, eclipse meteorology, snowfall and clouds. He showed in the early 19_0's that a downdraught was almost certainly an essential feature in the life-history of a thunderstorm, a finding the importance of which has only come to be generally appreciated in the past decade or so.

Dr. R. M. Goody

DR. R. M. GOODY, who was born in 1921, has been a Fellow and Scholar of St. John's College, Cambridge. He took his degree in physics in 1942 and for the next four years worked in the Ministry of Aircraft Production, first testing aircraft and later as a special duties officer in charge of a German research institute in Göttingen. In the course of this later work he was involved with the Control Commission in the first phases of the creation of the Max Planck Institutes. Dr. Goody took his Ph.D. in 1950 and was appointed Fellow of his College in that year. In 1951 he was awarded a Senior Studentship of the 1851 Exhibition and in 1953 he went to the Imperial College of Science and Technology as reader in meteorology. Since the War, Dr. Goody's interests have mainly been in the field of infra-red spectroscopy and its application to atmospheric problems, which has led him into the whole field of radiative transfer problems. He has done notable research on the stratosphere, and is the author of "The Physics of the Stratosphere" (Camb. Univ. Press, 1954). Recent research on the emission of radiation by atmospheric ozone has led him to a new method of determining the vertical distribution of ozone from observations at the ground. At present he is in charge of a small observatory of the Department of Meteorology, Imperial College, at Silwood Farm, Ascot. Dr. Goody will take up his new appointment in the summer of 1958.

The British Rainfall Organization: Memorial to G. J. Symons, F.R.S.

AN interesting dual ceremony was held in Camden Square, London, N.W., on August 8 under the auspices of the Royal Meteorological Society to honour the memory of George James Symons, pioneer in the scientific study of rainfall, and to mark the re-opening of the Society's historic London weather station on a new site. During the years 1854–58, repeated spells of drought made Symons see the need for assessing Britain's potential water resources by means of accurate and systematic measurements of rainfall. For this purpose he set about recruiting volunteer observers, and by 1860 was able to publish records from 168 gauges—all in England and Wales. Soon he extended the investigations to Scotland and Ireland. Public interest in the work grew so rapidly that the number of collaborating observers rose to two thousand within twenty years and reached 3,500 by the close of the nineteenth century. Thus was formed the British Rainfall Organization—a remarkable example of private enterprise supported mainly by voluntary effort. On Symons's death in 1900 he was replaced first by his chief assistant, H. Sowerby Wallis, and, shortly afterwards, by the late Dr. Hugh Robert

Mill, who retained control until the organization was taken over by the Meteorological Office in 1919. Since then it has continued to flourish with a corps of collaborating observers some five thousand strong. The Royal Meteorological Society has now commemorated Symons's great labours on behalf of science and the nation by affixing to the front wall of his former home in Camden Square a bronze plaque briefly recording his achievements and also his presidency of the Society on two occasions. This plaque was unveiled at noon on August 8 by the Mayor of St. Pancras, Councillor T. J. Redman.

The second ceremony on the same day was the formal opening by Dr. R. C. Sutcliffe, president of the Royal Meteorological Society, of a well-equipped climatological station which the Society, with the friendly co-operation of the St. Pancras Borough Council, has established on a chosen site in the small park of Camden Square. This station replaces one originally set up by Symons at 136 Camden Road (250 yards distant) in 1858 and transferred to the garden of his home at 62 Camden Square ten years later. Regular observations were maintained there by Symons and his successors until 1922, and have since been continued (not without difficulty) by the Royal Meteorological Society. These provide the longest unbroken day-to-day record of rainfall, temperature and weather anywhere in the county of London. Quasi-immortality for it is aimed at by the change of site from deteriorating private property more than a century old to an open space under municipal control. The World Meteorological Organization recommends that, for the study of secular climatic change, every nation should strive to keep at least one long-established weather station going in perpetuity. This the Royal Meteorological Society hopes to do at Camden Square.

Dr. Macalister Brew Scholarship Fund

The National Association of Mixed Clubs and Girls' Clubs is establishing a Dr. Macalister Brew Scholarship Fund. Dr. Brew was the Association's education and training adviser for fourteen years. The purpose of the Fund will be to enable young people, less than twenty-five years of age, to secure a term of further education, formal or informal, which they cannot finance themselves and for which no other aid is available. In accordance with the outlook of Dr. Brew, the precise nature of the awards will not be determined in advance but will depend upon needs arising from time to time. Further information about the Fund, together with extracts from some of the many public tributes which have been paid to Dr. Brew, can be obtained from Mr. S. H. Wood, N.A.M.C. and G.C., 30 Devonshire Street, London, W.1, to whom contributions should also be sent, cheques being made payable to "J.M.B. Scholarship Fund".

The Imperial Institute

In reply to a question in the House of Lords on August 1 regarding the Imperial Institute, the Minister of State for Colonial Affairs, the Earl of Perth, replying on behalf of Lord Hailsham, said that a suitable site has been found at the south end of the Holland Park Estate, and negotiations for a building lease, to be held in the first place by the Minister of Works, are at an advanced stage. The Bill which the Government hopes to introduce early next session will transfer all interests in the land from him to the trustees and will also provide for the cost of the new building to be borne on the Vote for the Ministry of Education. Lord Lloyd and Sir Alan Burns, he said, have accepted invitations to fill the place of the retiring trustees, Lord Brand and Sir Alfred Chester Beatty, and Lord Dundee is succeeding the late Viscount Hudson as chairman of the governing body. It is the intention of the trustees, with the help and advice of the governing body, to press ahead with the planning and erection of the new building. Lord Perth said that there will be no break in the work of the Institute, although some inconvenience will be inevitable. Investigations are still proceeding as to whether, in the development scheme for the Imperial College of Science and Technology, it will be possible to leave the Collcutt tower as a free-standing campanile at a reasonable cost.

In a written reply, Lord Perth gave the names of the trustees of the Imperial Institute, in addition to the two already mentioned, as the Lord President of the Council, the First Commissioner of the Treasury, the President of the Board of Trade, the Minister of Education and Viscount Southbury. The board of governors consists of the chairman, vice-chairman (Sir Griffith Williams), members appointed by the Governments of Canada, New Zealand, Australia, South Africa, India, Pakistan, Ceylon and the Federation of Rhodesia and Nyasaland (usually the High Commissioners or their deputies), nine governors appointed by the Minister of Education and three co-opted members.

Health in British Overseas Territories

The Secretary of State for the Colonies, Mr. Lennox-Boyd, stated in a written reply to a question in the House of Commons on July 30 regarding progress in the elimination of malaria and the treatment of leprosy and malaria during the past decade that malaria had been eliminated in Aden, Antigua, British Guiana (coastal areas), Cyprus, Mauritius, Nevis, St. Kitts, St. Vincent, Santiago and Tobago, and projects for its elimination are in preparation or in progress in British Honduras, Dominica, Grenada, Jamaica, North Borneo, Sarawak, St. Lucia, Trinidad and Zanzibar. Prospects in the African territories depend on the results of research and pilot projects in progress. Significant changes in the treatment of leprosy during the past three or four years has resulted in good progress in combating this disease, and provision is increasingly being made, as an alternative to long-term segregation, for out-patient treatment in clinics and rural dispensaries with the sulphone drugs in tablet form. Treatment is increasingly undertaken voluntarily, and in Northern Nigeria there are 468 treatment centres and 104,000 patients under voluntary treatment. Tuberculosis is now regarded as the greatest medical problem in British overseas territories, but in some non-tropical territories, such as Cyprus, Gibraltar and the Falkland Islands, there are indications that the disease is being successfully controlled. B.C.G. vaccination campaigns in Jamaica are beginning to bear fruit, and notification in Trinidad has fallen significantly. Surveys are still being undertaken, particularly in the African territories, with the assistance of the World Health Organization, and increased facilities for treatment have met with a ready response. In Hong Kong, the disease is the greatest single cause of death, but the death-rate is now falling. An important factor in the progress of the campaign is the attendance of medical practitioners and other personnel from the territories at tuberculosis courses in the United Kingdom.

Colleges of Advanced Technology

QUESTIONED in the House of Commons regarding the progress of the designated colleges of advanced technology, the Parliamentary Secretary to the Ministry of Education, Sir Edward Boyle, said in a written answer on August 1 that, at Bradford, Salford, and the Welsh College of Advanced Technology, Cardiff, new governing bodies have been set up, and at the other colleges the schemes of government have been modified, especially to give better representation to industry and commerce and other outside interests. At three of the colleges, new principals have been appointed and at all of them extra staff is being recruited. During 1957–58, the three colleges in London and the Loughborough College will be concentrating entirely on advanced work. All the colleges have been actively promoting new advanced courses, especially sandwich courses, and large-scale building developments are in progress at Salford and Birmingham, while plans for new buildings are being urgently prepared at Bradford, Cardiff and Loughborough.

Work on the National Institute for Nuclear Science

IN a written answer to a question in the House of Commons on July 30 regarding the National Institute for Nuclear Science, the Prime Minister said that the first task of the Institute has been to examine the proposals for the construction of a new particle accelerator. The design of this machine, a 7,000 MeV. proton synchrotron, which is expected to cost about £7 million, has now been agreed, and its construction, on a site adjacent to the Atomic Energy Research Establishment, Harwell, has been put in hand.

Nigerian Cotton

THE progress reports from experiment stations in Northern Nigeria for 1955–56 (pp. 25. London: Empire Cotton Growing Corporation, 1957. 9*d*.) record a commercial crop of 152,000 bales of 400-lb. cotton, the second largest ever recorded, although an even larger crop had been expected. This relative deficiency is attributed to excessive rainfall in three provinces in August and September, followed by an early and unusually abrupt onset of the completely rainless and cold weather, with extremely low humidities, of the Northern Nigerian winter. The general incidence of insect pests at Samaru did not appear notably higher than usual, but there is evidence that considerable loss of crop occurred from that cause, and this may also apply to the commercial crop, although at Kontagora and Mokwa damage was far heavier and a severe local outbreak of pink bollworm in northern Katsina also resulted in notable damage. Bacterial blight (*Xanthomonas malvacearum*) was not conspicuously more in evidence but may have done rather more damage, and over the greater part of the cotton belt the weather was such that failure to follow the rules of good cultivation probably incurred a heavier penalty than usual. In seed dressing trials with Agrosan *GN5* against bacterial blight, the protection given to the plants was reflected in the seed cotton yields, but in a spraying trial with 2 lb. DDT and 0·6 lb. gamma-BHC per acre at fortnightly intervals, although a 500 per cent increase in yield was obtained there was no significant difference in yield from different spacings, and last season's tentative conclusion that close spacing results in substantially higher yields was not confirmed at Kontagora. *Diparopsis watersi* was the most damaging bollworm at Samaru, but the highest incidence occurred at Kontagora. Together with pink bollworm, both false codling moth (*Argyroploce leucotreta* Meyr.) and spiny bollworm (*Earias* sp.) are assuming greater importance with the southerly extension of the main cotton-growing areas.

Ergot in Gramineae

THE well-known ergot disease (*Claviceps purpurea*) occurs on many grass species, including important cereal and forage crops. Further studies of the pathogenicity of this fungus have now been described by W. P. Campbell (*Canadian J. Bot.*, 35, 315; 1957). Four hundred and twenty-one isolates of *Claviceps purpurea* from thirty-eight different host species were cultured on an artificial medium. The conidial cultures were used for inoculating rye, wheat and barley growing in the greenhouse. All cultures, except one from *Glyceria borealis*, infected the three host species. Honeydew from rye was used for inoculating forty-six gramineous species in the field and in the greenhouse. Every one of these grasses became infected in both locations. The author has shown that all indigenous and forage grasses constitute a reservoir of ergot inoculum for rye, wheat and barley, and that these cereals can be infected provided the environmental conditions are such that inoculum will be disseminated at the time that the cereal crops are in blossom.

Medical Research Council Travelling Awards

THE Medical Research Council announces that it has made the following travelling awards for the academic year 1957–58. *Rockefeller Travelling Fellowships in Medicine*: Dr. J. Butler, senior registrar, Medical Professorial Unit, Queen Elizabeth Hospital, Birmingham; Dr. W. I. Cranston, assistant to the regius professor of medicine, University of Oxford; Dr. D. A. Heath, lecturer in pathology, University of Birmingham; Dr. F. P. Muldowney, University tutor in medicine, St. Vincent's Hospital, Dublin; Dr. W. L. Nicholas, lecturer in zoology, University of Liverpool; Dr. G. R. Webster, senior lecturer, Department of Chemical Pathology, Guy's Hospital Medical School. *Lederle Travelling Fellowship in Medicine*: Dr. A. M. Dawson, registrar, Department of Medicine, Postgraduate Medical School, London. *Dorothy Temple Cross Research Fellowship in Tuberculosis*: Dr. H. P. Lambert, registrar, University College Hospital, London. *Alexander Pigott Wernher Memorial Travelling Fellowships in Ophthalmology and Otology*: Dr. R. P. Gannon, medical officer, Royal Air Force, and officer in charge, Royal Air Force Acoustics Laboratory; Dr. D. M. Maurice, Medical Research Council Ophthalmological Research Unit, Institute of Ophthalmology, London; Dr. J. S. Speakman, resident in ophthalmology, Toronto General Hospital, Toronto. *French Exchange Scholarships in Medical Science*: Mr. B. L. Silver, research scholar, University College, London; Dr. Constance E. Work, first assistant, Department of Chemical Pathology, University College Hospital Medical School, London. *Lilly Foreign Fellowships*: The Eli Lilly Company of Indianapolis has also selected the following candidates, nominated by the Medical Research Council, for Lilly Foreign Fellowships administered by the Company: Dr. L. J. P. Duncan, lecturer in therapeutics, University of Edinburgh; and Dr. R. F. Mahler, lecturer in therapeutics, University of St. Andrews.

Ramsay Memorial Fellowship Awards

The Ramsay Memorial Fellowships Trustees have awarded fellowships in chemistry for 1957–58 as follow: Mr. T. E. Peacock, a general fellowship at the University College of North Staffordshire; a Glasgow fellowship to Mr. J. K. Sutherland at the Imperial College of Science and Technology, London; a Canadian fellowship to Dr. D. McK. Wiles, at the University of Leeds; a Japanese fellowship to Mr. M. Masui, at University College, London; a New Zealand fellowship to Mr. J. E. Fergusson, at University College, London; Spanish fellowships to Mr. P. Arambarri, at Rothamsted Experimental Station, and to Mr. D. Rodriguez, at the University of Sheffield; a Swiss fellowship to Dr. R. Humbelin, at University College, London. The Trustees have renewed the following fellowships for the same year: Dr. M. J. Stephen (general fellowship), at the University of Cambridge; Dr. G. S. Harris (Glasgow fellowship), at the University of Cambridge; Mr. C. H. Stam (Netherlands fellowship), at the University of Leeds; Dr. J. R. Villanueva (Spanish fellowship), at the University of Cambridge.

Conference on Industrial Carbon and Graphite

The Society of Chemical Industry is to hold a three-day Conference on "Industrial Carbon and Graphite" at the William Beveridge Hall, University of London, W.C.1, during September 24–26. Many countries, including the United States, the U.S.S.R., France and the Netherlands, will be represented, and more than fifty papers have been submitted. Carbon and graphite provide a wide and important field of study, especially in nuclear energy and electrical applications. Papers will be preprinted, and summarized at the Conference in selected groups, to enable the fullest discussion to be held during the Conference. Prior registration for membership of the Conference is necessary (£4 for non-members of the Society of Chemical Industry); application forms can be obtained from the Assistant Secretary, Society of Chemical Industry, 14 Belgrave Square, London, S.W.1, or from the Hon. Secretary of the Conference Committee, E. A. Smith, Acheson Industries (Europe), Ltd., 18 Pall Mall, London, S.W.1. Members of the Conference will receive preprints of all the papers. An exhibition of carbon and graphite will be held in the Department of Chemical Engineering, University College, Gower Street, London, W.C.1, during the Conference.

University News: London

The following appointments in the University of London are announced: Dr. S. D. Elek, reader in bacteriology at St. George's Hospital Medical School, to the chair of bacteriology tenable at that School; Dr. F. R. Johnson, lecturer in anatomy in the University of Sheffield, to the readership in anatomy tenable at the London Hospital Medical College; Dr. P. H. Spencer-Silver, to the readership in anatomy tenable at Middlesex Hospital Medical School. The title of reader in the University of London has been conferred on: Dr. J. B. E. Baker (pharmacology) in respect of his post at Charing Cross Hospital Medical School; Mr. E. A. Gellner (sociology) in respect of his post at the London School of Economics and Political Science; Dr. T. W. Glenister (anatomy) in respect of his post at Charing Cross Hospital Medical School; Miss D. M. Hall (chemistry) in respect of her post at Bedford College.

Announcements

Prof. Arthur Holmes, emeritus professor of geology in the University of Edinburgh, has been awarded the Paul Fourmarier Prize for 1947–56 of the Royal Academy of Belgium.

Mr. G. H. Hinds, electronics advisory officer, British Transport Commission, has been appointed (at the nomination of the Royal Society) a member of the General Board of the National Physical Laboratory. Mr. Hinds is also to serve on the Advisory Committee on High Speed Calculating Machines, Department of Scientific and Industrial Research.

The U.S. National Science Foundation has announced that its publications are available to all scientists who need them. Lists of publications are available from the Foundation; requests should be addressed to the Publications Office, National Science Foundation, Washington 25, D.C.

Reference was made in *Nature* of August 3, p. 218, to the translation service being organized by the British Iron and Steel Research Association and the Iron and Steel Institute. Inquiries in connexion with this service should be sent to the Institute, 4 Grosvenor Gardens, London, S.W.1.

The International Association of Microbiological Societies has at its disposal certain limited funds, which it receives from the International Union of Biological Sciences, for assisting the work of type culture collections of micro-organisms. Curators of such collections who make their type cultures internationally available and require financial help for this purpose are invited to make application, specifying their need, to the secretary of the International Association of Microbiological Societies, Prof. G. Penso, Istituto Superiore di Sanità, Viale Regina Elena 299, Rome.

The committee of the Oliver Memorial Fund is to make its annual award of £50 to a British subject whose original work or services in connexion with blood transfusion is considered to be a notable contribution to the research, organization or donor aspects of that subject. Applications and communications directing attention to suitable candidates must be submitted before September 30 to the honorary secretary, Mrs. F. E. Bedborough, 105 New Park Avenue, London, N.13, to whom all inquiries should be addressed.

The annual congress of the British Veterinary Association is to be held at Cambridge during August 25–31. All inquiries should be addressed to the Association at 7 Mansfield Street, Portland Place, London, W.1.

Erratum. In the communication "Amino-Acid Sequence of the α-Melanocyte-stimulating Hormone" by Dr. J. Ieuan Harris and Dr. Aaron B. Lerner in *Nature* of June 29, p. 1346, parts of the sequence indicated on p. 1347, col. 1, have been displaced. The vertical arrows pointing downward should be between 2 and 3, 7 and 8, and 9 and 10 respectively; the lower arrow pointing upwards should be between Arg. and Try.

FLOUR AND BREAD

THE 110th meeting of the Nutrition Society was held during July 5–6 in the Anatomy School, Cambridge. It took the form of a symposium on "Flour and Bread". In his introductory remarks the chairman, Sir Rudolph Peters, expressed the hope that the symposium would lead to a better appreciation of the essential facts on bread and flour and that discussion would be free from bias.

Dame Harriette Chick then summarized the fascinating history of wheat cultivation and bread-making from antiquity onwards, emphasizing that until comparatively recent times white bread was generally desired, being a sign of wealth and refinement. The unconventional, however, have always attributed health-giving virtues to the darker bread of the country folk, though there could formerly have been no informed arguments in support of this opinion, and the darkness of the country bread was due no less to inclusion of rye, barley, or even legumes, than to the use of meal of higher extraction. Furthermore, the refined flours from stone-milling must have contained more germ and aleurone layer than modern roller-milled white flour; the latter by the end of the nineteenth century was the common food of the British people.

Earlier scientific work on flour dealt with chemical and physical properties of its proteins—particularly of the gluten because of its importance in baking technology. From the middle of the past century, however, the nutritive value of the different parts of the grain has been studied. Dame Harriette emphasized the merits of the work during 1883–84 of Rubner and of Girard, particularly in showing the high protein content of the aleurone layer which in milling is separated with the bran. Later workers have shown that 80–90 per cent of this protein is available to human subjects. The proteins in wheat bran are richer than those of white flour in two of the essential amino-acids, namely, lysine and tryptophan, which is why animal-feeding experiments have shown that the value of white-flour protein is increased by the presence of a little bran.

The uneven distribution, in the grain, of essential nutrients other than protein was discovered about the period of the First World War. After recalling the pioneer researches on the cause of beriberi among rice-eaters, Dame Harriette mentioned that this disease, which at the time was puzzling the authorities, was diagnosed among Commonwealth troops on Lemnos by Col. C. J. Martin, at that time director of the Lister Institute; their diet had mainly been white bread and tinned meat. This led to the finding that the anti-beriberi factor was concentrated in the germ of both wheat and rice. The specification for 85 per cent National flour, recommended by the Accessory Food Factors Committee of the Lister Institute and the Medical Research Council, was a satisfactory compromise in that, while the nutritive value of the flour approached that of a 100 per cent meal, its fibre content was nearer to that of white flour. Research at the Research Association of British Flour-Millers had shown that the detail of this recommendation could be achieved in practice.

Dr. C. R. Jones used a simplified flow-sheet to explain the essentials of the flour-milling process and discussed the differences in nutrient content between the various flour streams that together form the straight-run flour. The compositions of these streams at different extraction-rates were shown. Vitamin B_1, in particular, is largely contained in a small proportion of the total flour from the end of the milling system, which incidentally is of poor bread-making quality. Data were given in illustration of the point that, even at a given extraction-rate, the 'natural' contents of nutrients in straight-run flour may vary considerably.

In a discussion that clearly greatly entertained her audience, Miss E. M. Widdowson considered some of the factors affecting the planning of human nutritional experiments and the difficulties encountered. She stressed that, in the first instance, it is well worth while to plan the perfect experiment, and then see how nearly the design can be put into practice. While avowing that the investigator should include himself among the experimental subjects, Dr. Widdowson remarked that any sort of nutritional experiment is bound to curtail one's social activities. Thus, the balance experiments in connexion with the effects of phytic acid in brown flour on calcium absorption lasted for nearly a year, with only one week-end free every four weeks. Particular difficulties encountered in the celebrated German experiments included the overcoming of a belief by those in charge of one home that it was morally wrong to allow children to eat *ad lib.* In one orphanage, where bread was given in addition to the inadequate German rations, the children grew less well than a similar group in another orphanage where no extra food was given. The reason was ascribed to the unsympathetic personality of the woman in charge of the first group; the children actually ate the extra food but failed to benefit from it.

Subsequent discussion showed that this last observation had created much interest. Mr. A. L. Bacharach inquired whether any data showing the effects of emotional disturbance had been obtained from animal feeding trials. Prof. R. A. McCance reminded the meeting that the secretions of the thyroid and pituitary glands may be affected by 'nerves'. Points made by other speakers were that a negative nitrogen balance is associated with emotional disturbance and that hospital experience shows that anxiety causes increased excretion of fat. Both the chairman and Dame Harriette refuted any suggestion that animal experiments are without significance in human nutrition by recalling signal discoveries made originally by means of experiments on animals.

Dr. Neil Jenkins, referring to the absence of evidence in support of the belief that high carbohydrate consumption promotes dental decay, and that brown bread is better than white in this respect, offered the following two suggestions. Flour, or bread, texture may be important; the extent to which food debris adheres to teeth is less after eating brown than after eating white bread. He also recalled T. B. Osborne's postulate that bran contains a factor that hinders attack on teeth by acids. Jenkins suggested this may be a phytate, since he has found that phytates reduce the rate at which calcium in extracted teeth will dissolve in acid media.

Prof. R. A. Morton recalled the formation of the Panel on Composition and Nutritive Value of Flour under the chairmanship of Sir Henry Cohen (now Lord Cohen of Birkenhead), of which he was a member, and gave a most interesting account of its considerations and conclusions. He stressed the consideration that while the adoption of an 80 per cent flour might conceivably ensure against possible but as yet unknown shortages in the diet, the enrichment of white flour would give more positive protection against clearly defined deficiency states. He personally was impressed by the hazy nature of the current assessment of requirements of several nutrients, especially in view of the possible occurrence of side-reactions.

Dr. H. M. Sinclair pointed out that flour, or bread, is the most important single item of diet in Britain. In 1947, 85 per cent extraction flour provided 27 per cent of calories consumed, 37 per cent of protein and about the same proportion of requirements of B_1, iron, phosphorus and nicotinic acid. Of the nutrients excluded from the present enrichment scheme, he considered that riboflavin was more important than was recognized by the Post-War Loaf Conference. As a single source of supply of riboflavin, bread is more important even than milk. He suggested that, if we must have white flour, riboflavin should be included in the enrichment policy, as in the United States and Canada.

As to whether, in other respects, enriched 70 per cent is equivalent to high-extraction flour, a table was presented showing that the contents of pyridoxin, biotin, folic acid, linoleic acid and vitamin E (α-tocopherol) were all materially lower in the white flour; only in the case of pantothenic acid was there no appreciable difference. In Dr. Sinclair's opinion, pyridoxin, linoleic acid and vitamin E have been grossly neglected and are very important in human nutrition. High-extraction flour is the most important single source of pyridoxin; but a decreased extraction-rate causes a serious reduction in our intake. On the other hand, judging from recently reported work with monkeys, human requirements may be met only to the extent of about one-third, even with 80 per cent extraction flour.

Dr. Sinclair tentatively estimates the contents of linoleic acid in 80 per cent and in 72 per cent flour as 0·8 and 0·5 per cent, respectively. Normally it is protected, both from atmospheric oxidation, and during body metabolism, by its accompanying vitamin E. The consideration may therefore be important that not only is vitamin E present initially to a smaller extent in white flour but also it is in any event destroyed by bleaching. Moreover, bleaching may not only destroy the essential-fatty-acid activity of the linoleic acid in flour but also may convert this substance into an antagonist that might increase the essential-fatty-acid requirement. Essential-fatty-acid deficiency might arise from dietary deficiencies in respect of linoleic acid, or of pyridoxin, or of vitamin E, since these are functionally interrelated, and in Dr. Sinclair's view it may be relevant to a variety of diseases of civilization, including coronary thrombosis and dental caries.

Dr. D. W. Kent-Jones, in presenting "The Case for Fortified White Flour", stressed the importance of the preference of the British public for white bread as against even the slightly darker 80 per cent extraction flour. It must also be remembered that destruction of certain nutrients occurs in cooking and baking, and only 65 per cent of all flour milled is made into bread; the rest is used for cakes, biscuits, home cooking, etc. The respective merits of breads made from long extraction and from enriched white flours had been comprehensively considered by the Cohen Committee, which took into account the Widdowson–McCance Report on the German experiments that may well be regarded as decisive. Nevertheless, the levels of fortification originally suggested by the Post-War Loaf Conference are now under re-examination by the Food Standards Committee, which is also considering whether fortification with riboflavin should be carried out. In presenting revised values for the contents of various B vitamins in flours of different extractions, Dr. Kent-Jones pointed out that lower-extraction flours are by no means devoid of the rarer components of the B complex; he also stressed that we know little of the actual daily requirements of most of them. He emphasized the importance of the Newfoundland experiment on the effects of white flour, enriched on the American scale, and of enriched margarine. This lasted more than four years, three hundred subjects being carefully examined before and after the experiment, during which visible signs of malnutrition, and also various mortality-rates, decreased. Moreover, quoting Wilder, "the quality of life had improved in Newfoundland". Dr. Kent-Jones also stressed that, in baking, half the vitamin E is destroyed, and in any event, cereals do not contribute much vitamin E to the diet.

A paper by J. R. Nicholls and J. R. Frazer, which was read by Dr. Nicholls, discussed analytical problems in the determination and control of extraction-rates of flour. Although extraction-rate is not an absolute yardstick for defining the grade of a flour, the term is widely used in industry and generally understood. The basic difficulty in its determination, by analysis of a sample, is that although 100 per cent extraction flour contains the whole of the bran, flours of lower extraction contain only selected fractions of the bran layers, which may differ in chemical composition from whole bran.

The authors reviewed various chemical constituents of flour and wheat and showed that none is strictly applicable to the determination of extraction-rate. The only practical course is to judge analytical values obtained on a given sample against corresponding data accumulated from an extensive survey of samples, having regard to the coefficient of variation found for each value. There is, however, a particular interest attached to the determination of starch, since this is provided practically entirely by the endosperm, while other carbohydrates are distributed to varying extents throughout the grain. The starch content of the endosperm is affected by the protein content, which varies considerably between wheats, but the ratio of non-starch carbohydrate to the sum of starch plus protein was offered as an approximate index of flour grade. Values for this index appeared characteristically dependent on extraction-rate and fairly independent of type of grist.

In opening the final discussion, the chairman acknowledged the differences in points of view and even in basic data offered by the several contributors, but hoped that these would be subjected to further scientific examination. Regarding the German experiment by Widdowson and McCance, he emphasized the possible significance of the soup supplied to the children as a source of important nutrients.

Dr. B. S. Platt challenged Dr. Kent-Jones's conclusion from the Newfoundland experiment that, in view of the health improvement found, high-extraction flour could have contributed no more than the enriched white flour actually used. The Wilder report had stated "not all the outward signs of malnutrition had decreased in prevalence. Only those had lessened which could have been affected by addition of vitamin A to margarine and of riboflavin, niacin and thiamine (B_1) to the flour". In replying, Dr. Kent-Jones interpreted Wilder as attributing the persistent signs to vitamin C deficiency, not to deficiencies for which the flour could have been held responsible.

Dr. E. Kodicek emphasized that a proportion of nicotinic acid in cereals is in the bound form and unavailable to a number of animals. On the other hand, nicotinic acid added by way of enrichment is wholly available.

Several contributors queried the claim that the public strongly preferred bread made from white flour to that from higher-extraction flour. In this connexion, Dr. J. B. M. Coppock referred to published evidence in support of the claim which had been obtained in a comprehensive survey on consumer preference recently carried out in Glasgow.

The relevance or otherwise of mortality statistics in relation to modern food habits and processing techniques was discussed both by Prof. J. J. Yudkin and Dr. Sinclair. The meeting ended appropriately with a plea by Mr. Bacharach for liberty of choice: members, he said, are free to express views but should not seek to force their adoption.

C. R. JONES

INSTITUTE OF BIOLOGY CONVERSAZIONE

THE annual conversazione of the Institute of Biology, London Branch, was held at the Imperial College of Science and Technology on the evening of June 25. Members and their guests were received in the Students' Union by Prof. P. H. Gregory (head of the Botany Department), F. Howarth (assistant director of the Botanical Laboratories) and Dr. H. O. J. Collier (chairman of the London Branch). A diversity of exhibits was displayed in the Botany Department, by courtesy of Prof. Gregory.

The word 'conversazione' has an Italian derivation and can be defined as a meeting of people for conversation and discussion, particularly on literary, scientific, antiquarian or artistic subjects. The emphasis is, therefore, on the facilities for social intercourse: these were admirably provided in the newly built Students' Union. To say that exhibits take second place to discussion at such a function is not to detract from their importance, for they themselves are the chief topics of conversation.

The Linnean Society of London, this year's guest society, provided an exhibit illustrating the evolution of the "Species Plantarum" by means of books and manuscripts, as well as items from Linnaeus's natural history collection, including insects, shells and plants. In addition, some of his own annotated works were exhibited and a map of the world showing journeys undertaken by his students to make collections. This was appropriate in the year of the 250th anniversary of the birth of Carl Linné, and provided an interesting comparison with 'Huxleyana', an exhibit showing some of the work of T. H. Huxley and presented by the Zoology Department of the Imperial College.

Each year the London Branch invites one firm of biological suppliers to provide a trade-stand, which, this year, was devoted to stains and reagents for microscopy, modern mounting media, water analysis tablets for field ecology and so on, presented by Edward Gurr, Ltd. Specimen publications were displayed by the Universities Federation for Animal Welfare, the quarterly journal *Medical and Biological Illustration* and the Institute of Biology. The London Branch's own exhibits included photographs taken during a week-end excursion to the Severn Wildfowl Trust and new trends in biological education.

It is not easy to decide which of the forty or more members' and guests' exhibits most deserve mention. Certainly one of the most original was a 'self-reproducing analogue' (Prof. L. S. Penrose and R. Penrose) recently described in *Nature* (179, 1183; 1957). Various suitably shaped wooden or plastic objects, when shaken in a trough, generate precise copies of themselves. The process has been termed pseudo-biosynthetics.

Living animals always attract interest and were a feature of several exhibits. In one (P. Hunter-Jones) normal hoppers and adults of the desert locust (*Schistocerca gregaria*), reared either in crowded conditions or in isolation—phases *gregaria* or *solitaria*—were compared with albino strains raised under similar conditions. In another (A. T. Thompson) could be seen representatives of some of the exotic grasshoppers kept at the Anti-Locust Research Centre. Cultures were shown of Pharaoh's ant (*Monomorium pharaonis*) (A. A. Green) and of the American dampwood termite *Zootermopsis angusticollis* (W. V. Harris and R. M. C. Williams). This insect provides a useful laboratory source of large protozoa, especially species of the genus *Trichonympha*.

Insects also appeared in exhibits of important species of tsetse fly with distribution maps and colour transparencies of their breeding habitats (Dr. J. R. Busvine), the biology of a British 'ambrosia beetle' (J. M. Baker), the use of 'Terylene' netting for studying the pattern of emergence and decay in a wheat bulb-fly population (J. W. Stephenson and R. W. Dobson) and in preparations of the genitalia of certain beetles (L. P. Lefkovitch). The effect of gamma-rays on ovarian development in the tsetse fly, *Glossina morsitans*, was illustrated by slides showing the ovaries of a 33-day-old female from an irradiated pupa, which were less developed than those of a 3-day-old female from a normal pupa (W. H. Potts).

In the fields of microbiology were exhibits of membrane filter techniques for concentrating and counting micro-organisms and new selective culture media (W. H. Pierce), some superb photographs of mammalian gametes (Dr. M. W. H. Bishop and Dr. C. R. Austin), preparations showing the cell structure of Cyanophyceae (Dr. J. K. Spearing), an antibody to *Trypanosoma vivax* present in normal cotton rat serum (Dr. R. J. Terry and Miss V. M. Smith), and tests for the antibiotic sensitivity of bacteria (W. A. Freeman).

Immunological exhibits also included the effect of insects in causing allergic symptoms in human beings (Dr. A. W. Frankland), a survey of the fungal spore and pollen content of the air (Miss E. D. Hamilton), immunology in agar cells (Dr. J. G. Feinberg, Dr. R. A. Grant and Miss H. Grayson), and gel diffusion methods for immunological assay (Miss B. J. Hayward).

The traditional use of dock leaves to allay the pain of nettle stings has led to the search for an antagonist of 5-hydroxytryptamine in dock-leaf extracts. The presence of such an antagonist and its action was demonstrated on *in vitro* preparations of smooth muscle (R. J. Brittain and Dr. H. O. J. Collier). The effect of drugs on the movements of the pig roundworm (*Ascaris* sp.) was recorded by means of a kymograph technique (Dr. L. G. Goodwin). The apparatus section included a light-scattering photometer (Dr. A. B. Taylor), a device for rapidly collecting samples of insects such as bees (L. Bailey), and apparatus for testing soil and plant tissue for mineral deficiencies (Dr. G. P. L. Miles).

Visitors were able to test their taste-threshold to phenylthiourea, which depends upon a single autosomal gene (Dr. H. Kalmus). The present writer, like one of his children, was unable to detect any flavour even in the strongest solution provided; his wife could distinguish something, but his other two children responded violently and vulgarly to its bitter taste. In contrast, all members of the family were able to appreciate the delicious home-made wine which formed an exhibit in the hobbies section (H. W. Appleton).

The hobbies of professional biologists are by no means without interest, but have not previously been represented in a London Branch Conversazione. The series of colour photographs of British orchids (J. H. P. Sankey), oil paintings (Dr. J. R. Busvine), drawings of caddis-flies (Dr. N. E. Hicken) and of flowers (Miss D. Potts), in particular, reached a high standard of artistry. Nevertheless, it is by the standard of the biological exhibits that the Conversazione should be judged. Throughout, they showed imagination and skill.

J. L. CLOUDSLEY-THOMPSON

WORLD HEALTH ORGANIZATION

REPORT FOR 1956

IN his annual report on the work of the World Health Organization for 1956*, Dr. M. G. Candau, the director-general, reviews the beneficent work of the Organization during the past few years and discusses plans for the future.

Considering malaria first, he recalls the recommendation made by the eighth World Health Assembly, held in Mexico, that eradication of malaria, not its mere control, should be the aim, and that an expert committee, which met after the conference of malariologists held in June 1956, drew up a realistic guide for the planning and carrying out of programmes of eradication of the disease. This policy of eradication was adopted because, in addition to long-range economic considerations, the *Anopheles* mosquitoes which are the vectors of malaria became resistant to the insecticides used for their control. Research, which must always back up field work, has shown that, in some instances, mosquitoes resistant to DDT can be controlled by insecticides of the benzene hexachloride type, but that, in some parts of Greece, the mosquitoes are resistant to both these groups of insecticides and, wherever this occurs, other methods of control have to be devised. Preliminary studies promoted by the World Health Organization have shown that the distribution to peoples of salt-containing antimalarial drugs has given encouraging results. Two other antimalarial problems under investigation, both of them important in Africa, are the sorption of insecticides by the mud walls of houses, and the behaviour of the chief vector of malaria in Africa, *Anopheles gambiae*.

The section of the report devoted to malaria is especially interesting because it is illustrated not only by photographs of antimalarial work in Iraq and Mexico, but also by four valuable maps, which show at a glance the distribution of antimalarial activities in Europe, Africa, Asia and North and South America and the progress to date, so far as the latest information permits, of control and eradication programmes. These maps show, for example, that eradication is practically or fully achieved in the western United States and the Californian region, in Puerto Rico, Northern Chile, French Guiana, parts of Venezuela and British Guiana, in the greater part of Ceylon and, in Europe, in Italy, Corsica, Sardinia, Cyprus and Crete. Elsewhere the vigorous campaigns assisted by the World Health Organization are likely, in due course, to rid the world of a disease which is still one of the major menaces to mankind.

This cannot be done, however, without the research work which is, the director-general rightly insists, "the real backbone through which the Organization is striving to promote World Health". It is also a basic function of the World Health Organization to pool all available scientific and technical knowledge, to appraise this knowledge constantly and to study how best it can be applied to problems of public health wherever they occur. Malaria is not by any means the only disease transmitted by insect vectors, and the general problem of the resistance of vectors of disease to insecticides has been tackled by a survey of research. Experts appointed by the World Health Organization have visited more than one hundred laboratories concerned with this problem and the gaps in our knowledge have been defined. Co-ordination of the work of several scientific institutes has developed basic methods of measuring the susceptibility or resistance of vector populations—for example, the lice of man—with the result that the World Health Organization is now able to advise the best method of control, and there has in consequence been a betterment of the control of typhus fever, which is transmitted by lice.

In a different field of work a series of projects initiated by the World Health Organization and its experts has greatly advanced the control of rabies. The efficacy of hyperimmune serum has been demonstrated, and field trials in Iraq on the use of serum in persons exposed to rabies, in Spain on the local treatment of wounds inflicted by animals suffering from rabies, in Malaya and Israel on new vaccines for the control of rabies in animals, and in France and the United States on the standardization of the potency of vaccines and sera, have all contributed much to the control of this disease. An important recent step has been the institution of an international standard serum and a reference vaccine.

---

* Official Records of the World Health Organization No. 75: The Work of WHO 1956—Annual Report of the Director General to the World Health Assembly and to the United Nations. Pp. xi+233+16 pages of photographs. (Geneva: World Health Organization; London: H.M. Stationery Office, 1957.) 6 Swiss francs; 10s.; 2 dollars.

This is part of one basic task of the World Health Organization, that of providing medical science with units of measurement, a task which involves much intensive research, under the guidance of expert committees, in laboratories all over the world. Wherever vaccines are concerned, strictly controlled field trials are needed to relate the results of tests made on animals to those expected in man, and work of this kind has shown, as a result of a long series of studies, undertaken by the World Health Organization during 1952–56, that a dry smallpox vaccine can be prepared, which is stable at 45° C. for two years at least. This dry vaccine should improve the control of smallpox in hot countries, and an international reference standard for it is now being prepared.

Among other subjects discussed by the director-general are the psychobiological development of children and endemic goitre. For the treatment of goitre it has been found that iodates are more effective than iodides, and that sodium iodate has a very low toxicity. The World Health Organization therefore appointed experts to assist countries in Latin America in the production of iodized salt for their peoples.

Another aspect of the work of the Organization is concerned with the work of international centres or laboratories which exist for the study of influenza, poliomyelitis, treponematoses, leptospirosis, brucellosis and other bacterial and virus diseases, as well as for biological standardization and blood-grouping. The study of poliomyelitis has shown that, in countries with a high incidence of the paralytic form of this disease, the use of a vaccine is an effective method of reducing its serious effects. Prospects for the control of leprosy have been improved by the discovery of the sulphone drugs, and recent reports confirm that BCG vaccination has a real effect in reducing the incidence of tuberculosis, although, to control the disease, this must be combined with case-finding and treatment.

The director-general emphasizes that, in all work on communicable diseases, thorough and comprehensive planning is necessary. The application of a new method of control, or the adaptation of an established technique, needs careful pilot studies if success is to be ensured. It is realized, too, that technical knowledge and methods are not enough; success will depend on administration, training of personnel, sound technical application and financial support. The organization of public health services is being governed increasingly by the concept of integrated services, rather than by that of services separately provided for specific, limited fields. These integrated services are, for example, being applied in nutrition, maternal and child health and in health education.

More recently the Organization has been concerned with atomic energy in relation to health. The aspects of this general problem being studied are training, the collection and distribution of information on the medical problems that arise and on the medical uses of radioisotopes, the study of health problems arising from the disposal of radioactive waste, international work on the distribution of radiation standards and, related to these, on codes of practice and specifications for the preparation of radioisotopes for medical use, and the stimulation and co-ordination of research on the health aspects of radiation.

An important part of the report describes the work being done in each of the six regions into which the World Health Organization divides the world. There is a detailed list of the numerous projects in operation during the year, and the human aspect of all this work is shown by the excellent photographs selected from typical projects in many parts of the world. To some readers these photographs will tell, more graphically than words can, how widespread, effective and beneficent is the work of the Organization.

G. LAPAGE

INSTRUMENTS FOR MICRO-METEOROLOGICAL MEASUREMENTS

FOR measuring the variations of temperature, humidity, and wind speed near the ground and in growing crops special apparatus is necessary. The spatial rates of change are large compared with those at the height of 4 ft. at which the ordinary screen readings are taken, and on this account specially small apparatus is necessary. Much work has been done on this subject in recent years at Rothamsted Agricultural Experimental Station, and Mr. H. F. Long has recently described the apparatus devised and its properties (*Quart. J. Roy. Meteor. Soc.*, 83, 202; 1957).

Temperature measurements are made with small resistance thermometers of either the thermistor or nickel wire type. The latter are more stable for purposes of continuous recording. The nickel wire elements used for measuring dry- and wet-bulb temperatures and in the 'hot bulb' anemometer were wound on plastic bobbins 1 mm. in diameter, 3 mm. total diameter with the wire, and 10 mm. long. Still smaller elements 0·8 mm. in total diameter and 5 mm. long were made for measuring the temperature of potato leaves by fitting them into holes made in the leaves with a hypodermic syringe. The elements used for measuring air temperature were protected from radiation by small half-cylinders of copper gauze painted white.

The fact that, at about 10° C. in air which is not too dry, the dew-point is roughly the mean of the dry- and wet-bulb temperatures is used by suitable circuit arrangements for obtaining a rough record of dew-point. Two such sets at different heights balanced against each other give a very sensitive measure of dew-point differences and also enable the times of dew formation, of particular importance to the Rothamsted workers in connexion with fungus disease of potatoes, to be determined very accurately.

For measuring wind speed in the range 5–70 cm./sec. a 'hot bulb' anemometer is used. This has two nickel wire resistance thermometers, one of which is heated by an electric heater. Cooling by the wind tends to equalize the temperatures of the heated and unheated bulbs, and the out-of-balance current in the central galvanometer of a Wheatstone bridge containing the two elements gives a measure of wind speed. Full details of the construction of the instruments and their calibration and degree of accuracy are given in the article. The instruments might well have applications in industrial processes in which accurate readings of temperature, humidity, and air flow are needed.

RATE OF ENTRY OF RADIOACTIVE STRONTIUM INTO PLANTS FROM SOIL

By DR. R. SCOTT RUSSELL and G. M. MILBOURN

Agricultural Research Council Radiobiological Laboratory, Compton, Nr. Newbury, Berks

PART of the strontium-90 which descends to the Earth's surface in fall-out from nuclear test explosions will lodge on the foliage of plants, part will enter the soil. The relative magnitude of these fractions may vary widely, depending on the nature of the vegetation cover and the rainfall; but it appears that the greater part of the deposition will find its way into the soil. Knowledge of its fate therein is therefore vital if the consequences of fall-out are to be fully assessed. From the practical point of view it is particularly important to determine the fraction of the strontium-90 which is likely to be absorbed by crops in each successive season, and the ratio of strontium-90 to calcium which will occur in them. The close relationship between the metabolism of strontium and calcium in animals indicates the importance of the latter question.

The rate of absorption of strontium-90 will depend on the character of the soil, the climate and the vegetation. Thus the study of this subject on an adequate scale presents obvious difficulties. Two methods of investigation are possible—the survey of current fall-out and tracer experiments. The survey procedure has the attraction that the behaviour of actual fall-out is observed, but quantitative data are difficult to obtain since all herbage is likely to be contaminated to some extent by direct aerial deposition as well as by absorption from the soil. Furthermore, the problems associated with measuring the very low levels of strontium-90 which have been so far deposited demand elaborate techniques. Tracer experiments by contrast provide a simple and precise method for ascertaining the fraction of a given application of radioactive strontium which enters plants. Since it is known that long-range fall-out is relatively soluble, such experiments should provide a realistic basis for assessment provided that: (*a*) the tracer is applied to the surface of the soil in a soluble carrier-free form in much the same manner as if it were washed down by rain; (*b*) experiments are carried out under field conditions, thus avoiding abnormalities in root distribution such as may occur in pot or greenhouse experiments.

Experiments of this type should provide information on situations which would occur in the worst case, namely, if all the fall-out strontium were freely soluble. The absorption by plants would be less if part of the deposition were contained in sparingly soluble particles; prudence, however, indicates the importance of obtaining knowledge of the worst situation which could occur. Such experiments could serve the further purpose of providing information on the extent to which the absorption of fall-out strontium could be modified by altering cultivation practices in an emergency. Field experiments have therefore been undertaken by the Agricultural Research Council Radiobiological Laboratory, Compton, Berks. The short-lived isotope strontium-89 (half-life 54 days) has been used for reasons of safety in preference to the long-lived strontium-90. The first experiment, which is here described, was carried out in 1956 on a chalk downland in Berkshire. The work is now being extended to five representative areas of other soil types in different parts of the country. The Ministry of Agriculture, Fisheries and Food is collaborating in these investigations.

The strontium-89 was applied to the surface of the land in the form of a spray at the rate of 66 μcurie/metre^2. A commercial field sprayer modified in the manner described later enabled this operation to be carried out in safety. The volume of the solution used was equivalent to 100 gallons/acre. It appeared possible that the extent to which the simulated fall-out would enter plant roots might be influenced by whether it fell directly on the ground surface or lodged on plant tissues which were afterwards ploughed into the soil. Accordingly, land carrying stubble at the time of contamination was compared with bare fallow. Three subsequent cultivations were employed—rotary cultivation to the depth of 4 in., normal ploughing to the depth of 7 in., and double ploughing (7 in. followed by 12 in.). In this way it was hoped to obtain the greatest practicable variation in the manner in which the contamination was placed in the seed bed. A single deep ploughing to the depth of 12 in. was not possible with the available equipment because of the hardness of the subsoil, which was within 9 in. of the ground surface. Three crops, rye-grass, sugar-beet and barley, were afterwards planted. The eighteen combinations of conditions of the soil × cultivations × crops were employed in four-fold replication, the plot size being 4 yd. × 8 yd. Half of each plot received lime at the rate of 2 tons per acre. Two cuts of rye-grass were taken; the above-ground parts of the other crops were sampled at the time of harvest.

Complete randomization of the initial condition of the land and the cultivation treatments was impracticable. The consequent restriction on the precision with which treatments could be compared has made it possible to establish the statistical significance of effects only when their magnitude is large.

In the planning and conduct of the experiment the Laboratory enjoyed the close co-operation of the Health Physics Division, Atomic Energy Research Establishment, Harwell. A site remote from buildings or water supplies was selected and surrounded by a chain-link fence. The spraying equipment, which was mounted on a tractor, was modified to enable the boom to be readily removed and decontaminated (Fig. 1). The drift of spray and the exposure of personnel were reduced by the following procedures: employing a boom hood from which a polythene apron reached as near as practicable to the ground surface; using a large droplet size; and spraying head-on into the wind when the wind-speed was less

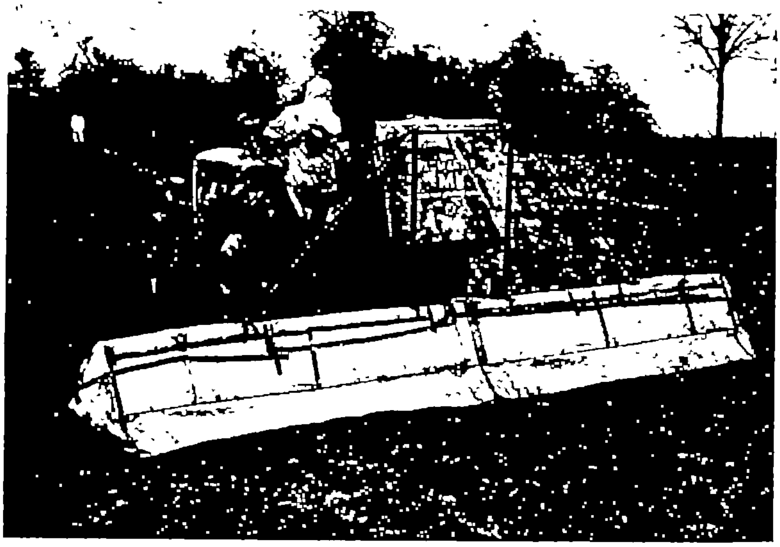

Fig. 1. Spraying equipment for the application of strontium-89 in the field

than 4 m.p.h. Polythene sheeting and strippable paint were employed to facilitate decontamination on both tractor and spray tank. Air samplers were mounted in front of the tractor driver and on a 'Land Rover' which followed the tractor 20 yd. down wind. Polythene protective clothing and respirators were worn by the tractor driver and 'Land Rover' crew. Similar precautions were taken in subsequent cultivations. The highest air-borne contamination was recorded on the 'Land Rover' during spraying but did not exceed one-hundredth of the maximum permissible level for occupational exposure recommended by the International Commission for Radiological Protection. After spraying was complete, the spray boom and hood were sealed in polythene sheeting; the decontamination of other equipment presented no problems. These results imply that a very adequate standard of safety was maintained. In fact, from the experimental point of view, the degree of air-borne contamination was unfortunately low; during the ploughing operation it was below the level at which precise measurements could be made by the sensitive survey instruments employed. Thus no exact calculation was possible of the degree of hazard which would result from the cultivation of land of this type if it were contaminated with a heavy level of fall-out.

Table 1. Absorption of Strontium-89 and the Ratio of Strontium-89 to Calcium for Sugar-Beet, Rye-grass and Barley

Crop	Yield per acre (cwt.)	Sr-89 content as per cent of dose	Sr-89/Ca ratio (mμc./gm. Ca)
Sugar-beet			
Tops		0·61 ± 0·020	26·6 ± 1·2
Roots	164·0	0·17 ± 0·010	46·5 ± 2·6
Total		0·78	
Rye-grass			
1st cut	18·92	0·390 ± 0·034	43·1 ± 4·1
2nd cut	7·33	0·072 ± 0·005	44·0 ± 1·7
Total	26·25	0·462	
Barley			
Grain	26·0	0·016 ± 0·002	52·6 ± 5·6
Straw		0·106 ± 0·007	54·7 ± 2·7
Total		0·122	
Significant difference between all crop parts	5 per cent	0·067	10·0
	1 ,,	0·091	13·4
	0·1 ,,	0·122	17·7

The salient features of the results are summarized in Tables 1–3. A more detailed discussion will be presented elsewhere. The mean figures for each crop (Table 1) show that crop yields were within the normal agricultural range for the area. The fraction of the strontium-89 which the crops absorbed ranged from 0·12 per cent for barley (grain and straw) to 0·78 per cent in sugar-beet (shoots and storage organs). The strontium-89/calcium ratio was in the same general order for all tissues except in the leaves of sugar-beet, which showed markedly lower values; this observation accords with the findings of other investigators that the strontium-89/calcium ratio is higher in roots than shoots[1,2]. It would be unwarranted to infer from a comparison of the values of the aerial parts of the three species that sugar-beet shows intrinsically different discrimination against strontium; differences in the distribution of roots could cause this effect since the contamination was not uniformly distributed through the soil (Table 3).

Table 2. Summary of Effects of Treatment on all Crops

	Sr-89 content as per cent of dose applied	Sr-89/Ca ratio (mμc./gm. Ca)
Condition of land at time of spraying		
Fallow	0·40	39·3
Stubble	0·50	48·5
		Significant difference 6·8 (5%)
Cultivations		
Rotary cultivation	0·388	38·0
Shallow ploughing	0·526	49·6
Double ploughing	0·442	44·1
		Significant difference 7·1 (5%) 9·5 (1%)
Liming		
Limed	0·444	43·0
Non-limed	0·458	44·6
		No significant difference

Table 3. Percentage Distribution of Strontium-89 in Soil Profile following Cultivation Treatments

	Horizon (in.)		
	0–4	4–8	8–12
Cultivations			
Rotary cultivation	86·1	8·9	5·0
Shallow ploughing	45·9	50·6	3·4
Double ploughing	70·3	22·4	7·3
Significant difference 18·6 (5 per cent)			

The mean effects of the various experimental treatments on all the crops are summarized in Table 2. No significant effects on the absorption of calcium were induced. Thus the absorption of strontium-89 and the strontium-89/calcium ratio were affected similarly. On the average of all crops the strontium-89 values were 25 per cent greater when the land had been under stubble than in bare fallow at the time of contamination. The extent of the effect varied between crops and was maximum in the first cut of rye-grass when the values for the strontium-89/calcium ratio were:

Fallow	3·17
Stubble	5·45
Significant difference (5 per cent)	1·95

It appears, therefore, that contamination absorbed on herbage which is afterwards ploughed into the soil is more readily available to plants than contamination directly incorporated into the labile cation complex of the soil. This effect would be expected to decrease with time; the fact that no significant difference was observed in the second cut of rye-grass supports this view.

The effects of the cultivation treatment on the distribution of strontium-89 down the soil profile are shown in Table 3. Except in the shallow ploughing treatments more than 70 per cent of the contamination was found in the upper 4 in.; the second ploughing of the double ploughing treatment had apparently returned an appreciable fraction of the contamination to a higher level. Shallow ploughing led to the greatest strontium-89 content in all crops; the maximum effect again occurred in the first cut of rye-grass and the values for the strontium-89/calcium ratio were:

Rotary cultivation	3·15
Shallow ploughing	6·28
Double ploughing	3·50
Significant difference (1 per cent)	3·06

No effect of cultivation was, however, apparent in the second cut.

The present experiments indicate that less than 1 per cent of the strontium-89 was recovered by crops in one year. Under very different conditions of soil and climate, Reitemeier[3] found values ranged from 0·5 to 1·5 per cent for soya-beans and broom-grass. Further results must, however, be awaited before a generalization can be made regarding the situation for soils in Great Britain.

Because of the relationship between calcium and strontium in the absorption process the view has been encouraged that liming will reduce the uptake of strontium-90. The absence of any effect in this experiment, however, agrees with the results of numerous small-scale experiments which indicate that the strontium-90/calcium ratio in plants is likely to be affected by liming to an important extent only in soils which contain inadequate calcium for crop production[2].

The present results suggest that the alteration of cultivation methods will not affect the absorption of fall-out strontium to a marked extent except in the early stages of the growth of crops. The possibility of some mitigation when shallow-rooted plants are grown in soils which can be ploughed deeply in a single operation cannot, however, at present be excluded.

The primary object of this preliminary report is to direct attention to the desirability of obtaining data on as wide a scale as possible. It is to be emphasized, however, that, because of the rapid decay of strontium-89, experiments with this isotope can provide information only on absorption in the year immediately following contamination. There are reasons for believing that the physico-chemical equilibration in the soil may cause the absorption of strontium-90 to decrease with time to a greater extent than would be predicted on the basis of its decay-rate[1]. This can, however, be verified only by experiments with strontium-90, which for reasons of health can be carried out only on a very restricted scale.

CORRELATION BETWEEN PHOTONS, IN COHERENT BEAMS OF LIGHT, DETECTED BY A COINCIDENCE COUNTING TECHNIQUE

By R. Q. TWISS and A. G. LITTLE

Division of Radiophysics, Commonwealth Scientific and Industrial Research Organization, Sydney

AND

R. HANBURY BROWN

University of Manchester Jodrell Bank Experimental Station

THERE has recently been a controversy[1–4] in the columns of *Nature* on the existence of a correlation between photons in coherent beams of light. In the initial communication[1], by Hanbury Brown and Twiss, an experiment was described in which light from a pinhole source was split, by a semi-transparent mirror, into two separate beams which then illuminated the cathodes of two separate phototubes. As long as the two light beams were partially coherent a correlation was observed between the fluctuations in the anode currents of the two phototubes and it was argued that this proved that the arrival times of light quanta at different points illuminated by coherent beams of light were correlated.

This experiment was criticized by Brannen and Ferguson[2], who had themselves carried out a somewhat different test, in which the simultaneous emission of photoelectrons at the two photocathodes were recorded by a coincidence counter, and in which no significant difference was observed in the number of counts with coherent or incoherent light. Furthermore, these authors suggested that the results obtained by Hanbury Brown and Twiss were due, not to a true correlation between the arrival times of quanta, but to some other cause such as an intensity fluctuation in the light source.

In reply it was pointed out by Purcell[3] and by Hanbury Brown and Twiss[4] that there was no real disagreement between the results of these two tests, since the experiment of Brannen and Ferguson[2], and the similar experiment of Ádám, Jánossy and Varga[5], were far too insensitive to detect the effect. In addition, the reality of the phenomenon has been confirmed by observations[6] on Sirius; also the experiment of Hanbury Brown and Twiss has been repeated under precisely controlled conditions, when the observed correlation, with various degrees of optical superimposition of the photocathodes, agreed within a few per cent with the predictions of theory (unpublished work).

However, to make assurance doubly sure, we have repeated the experiment of Brannen and Ferguson, under conditions which permit the detection of the effect, and have obtained a positive result, in reasonable agreement with theory, as described below.

If a correlation between photons is to be detected in a convenient time by the coincidence counter technique it can be shown, not only that the light source must be brilliant, but also that the light reaching the photocathodes must be confined to a very narrow band. This immediately suggests the use of an isotope lamp and, in the present experiment, the light source was an electrodeless radio-frequency discharge in mercury-198 vapour, cooled by a forced air draught, to which the radio-frequency oscillator delivered 1½ watts of power at a frequency of 800 Mc./s. In other respects the experimental arrangement was very similar to that of Brannen and Ferguson[2], employing *1P*21 phototubes, the coincidence circuit being that of Bell, Graham and Petch[7], with a resolution time of $3 \cdot 5 \times 10^{-9}$ sec.

The light source was limited by a pinhole 0·360 mm. in diameter; the photocathodes, at a distance of 1·25 metres, were limited by square apertures, 2 mm. × 2 mm., and the 5461 A. line was isolated by an optical filter. Both phototubes were mounted on movable slides so that, as seen by the source, they could be optically superimposed or separated by a distance of 5 mm. transverse to the line of sight; at the latter distance the pinhole source was completely resolved so that the incident light beams were effectively uncorrelated. The photon counts could also be uncorrelated by inserting a length of cable in one channel of the coincidence counter circuit with a delay of 15 mμsec., about four times the resolution time of the coincidence circuit.

The measurements were carried out as follows. The photocathodes were optically superimposed for two minutes and the number of coincidences n_{1r} observed in this interval was recorded. One or other of the photocathodes was then moved to the displaced position, and n_{2r}, the number of coincidences in a two-minute period, was also recorded. This procedure was repeated ten times in a run in which the total observation time was 40 min. and the difference

$$\Delta n_c = \sum_{r=1}^{10} (n_{1r} - n_{2r}) \qquad (1)$$

was measured. In order to eliminate the effect of any difference in the light intensity reaching the two different positions of the photocathode, an identical comparison run was then made with the extra cable inserted in one arm of the coincidence circuit and the difference

$$\Delta n'_c = \sum_{r=1}^{10} (n'_{1r} - n'_{2r}) \qquad (2)$$

between the coincidences observed with the photocathodes superimposed and displaced was recorded. The quantity $N_c = (\Delta n_c - \Delta n'_c)$ was then taken as a measure of the number of correlated photoelectrons emitted in coincidence during a 20-min. interval.

A total of six such tests, with an overall observation time of 480 min., were performed, and the results are shown in Table 1. Combining all the measurements, we conclude that the ratio ρ of the correlated to the random counts is given by

$$\rho_{\text{exp.}} = 0 \cdot 0193 \pm 0 \cdot 0017 \text{ (probable error)} \qquad (3)$$

The probability that this result is a random noise fluctuation is quite negligible, being less than 1 in 10^{15}; in addition, the possibility that it was significantly affected by drifts was eliminated by stabilizing the light intensity and the power supplies to the phototubes, with the result that any such drifts in the counting rate in a 40-min. run were too small, compared with the random fluctuation, to be detected.

A seventh run was then taken with the isotope light source replaced by a tungsten filament lamp, under which conditions no significant correlation is to be expected. As may be seen from Table 1, no significant correlation was in fact observed.

The experimental results have been compared with theory as follows. It has been shown by Purcell[3] that the theoretical ratio ρ of the correlated to the random coincidences is given by

$$\rho_{\text{theor.}} = \frac{\tau_0}{4\tau_c} \qquad (4)$$

in the idealized case of a point source and unpolarized light. In this expression τ_c is the resolving time of the coincidence counter, and $c\tau_0$ is the 'coherence length' of the light when τ_0, which is approximately equal to the reciprocal light bandwidth, is defined by

$$\tau_0 = \int_{-\infty}^{\infty} | g^2(t) | \, dt \qquad (5)$$

and $g(t)$, the Fourier transform of $f(\nu - \nu_0)$, the normalized spectral density of the incident light centred on frequency ν_0, is defined by

Table 1. RATIO OF CORRELATED TO RANDOM COINCIDENCES

Run No.	Observed number of coincidences in 20 min.* (N_T)	Observed number of correlated coincidences in 20 min. (N_c)	Percentage ratio of correlated to total coincidences ($\rho \times 100$)	Ratio of correlated coincidences to r.m.s. uncertainty in random coincidences† ($N_c/2(N_T)^{1/2}$)
1	136,941	2,986	2·18	4·03
2	130,067	2,190	1·68	3·04
3	137,435	2,369	1·72	3·2
4	100,732	2,185	2·18	3·43
5	97,258	1,864	1·93	3·0
6	94,739	1,761	1·86	2·8
7	81,576	185	0·22	0·33‡

* The average number of photoelectrons emitted in a 20 min. interval was of the order of 10^8.

† In deriving the root-mean-square uncertainty in the number of random coincidences it was assumed that they obeyed a Poisson distribution. The root-mean-square uncertainty for any one run is twice the square root of the number of coincidences observed in 20 min. since, as explained in the text, each run consisted of four 20 min. observation periods.

‡ Run No. 7 was taken with a broad bandwidth light source, a tungsten filament lamp, for which no significant correlation was expected.

$$g(t) = \int_{-\infty}^{\infty} f(\nu) \exp (2\pi i \nu t) d\nu \qquad (6)$$

The resolving time τ_c of the coincidence counter was measured to be $3 \cdot 5 \times 10^{-9}$ sec. under the conditions of the present experiment. The value of τ_0 for the mercury isotope lamp was measured by observing the visibility of fringes in a Michelson interferometer as a function of mirror spacing, and was found to be $0 \cdot 73 \times 10^{-9}$ sec.; this is somewhat smaller than the ideal value to be expected from a lamp of this kind with an atomic temperature of ~ 300° K., but the decrease is caused by self-absorption at the centre of the line.

In applying equation (4) to the present equipment it is necessary to reduce the theoretical value of ρ by a factor $\Delta(\nu_0)\gamma$; where $\Delta(\nu_0)$ is the 'partial coherence' factor which allows for the fact that the source is of finite angular size and is therefore partially resolved by the individual photocathodes, and γ takes into account the polarization introduced by the semi-transparent mirror and the false counts due to dark current in the phototubes. The value of $\Delta(\nu_0)$ was calculated to be $0 \cdot 475$, and γ was measured to be $0 \cdot 86$.

With the numerical values given above, the theoretical value for ρ is

$$\rho_{\text{theor.}} = \Delta(\nu_0)\gamma\frac{\tau_0}{4\tau_c} = 0 \cdot 0207 \qquad (7)$$

The error in this value is unlikely to exceed $\pm 0 \cdot 002$ and is principally caused by uncertainties in the value of τ_c, which in turn depends, in a complex manner, upon the amplitude distribution of the pulses from the phototubes.

A comparison of equations (3) and (7) shows that the experimental and theoretical values for the fraction of photoelectrons which are correlated and emitted in time coincidence are in satisfactory agreement, the discrepancy being less than the probable error in the measurement or the uncertainty in the theoretical value. Thus the present experiment confirms the conclusions drawn from the earlier test[1], and shows in a very direct manner that the arrival times of photons at different points are correlated when these points are illuminated by coherent beams of light.

We should like to thank Prof. R. E. Bell for very helpful advice on the operating conditions of the coincidence circuit, and the Division of Electrotechnology of the Commonwealth Scientific and Industrial Research Organization for the use of its high-speed counter. A detailed discussion of this and allied experiments will be submitted for publication in the *Australian Journal of Physics*.

GENE MUTATIONS IN HUMAN HÆMOGLOBIN: THE CHEMICAL DIFFERENCE BETWEEN NORMAL AND SICKLE CELL HÆMOGLOBIN

By DR. V. M. INGRAM

Medical Research Council Unit for the Study of the Molecular Structure of Biological Systems, Cavendish Laboratory, University of Cambridge

I REPORTED recently[1] that the globins of normal and sickle cell anæmia human hæmoglobins differed only in a small portion of their polypeptide chains. I have now found that out of nearly 300 amino-acids in the two proteins, only one is different; one of the glutamic acid residues of normal hæmoglobin is replaced by a valine residue in sickle cell anæmia hæmoglobin. The latter is an abnormal protein which is inherited in a strictly Mendelian manner; it is now possible to show, for the first time, the effect of a single gene mutation as a change in one amino-acid of the hæmoglobin polypeptide chain for the manufacture of which that gene is responsible.

In previous experiments[1], tryptic digests of the two proteins had been prepared; the resulting mixtures of small peptides were separated on a sheet of paper, using electrophoresis in one direction and partition chromatography in the other. These paper chromatograms derived from the two proteins, which I had called 'finger-prints', showed all peptides to have identical electrophoretic and chromatographic properties, except for one spot, peptide No. 4. This occupied different positions in the 'finger-prints' of normal (Hb *A*) and sickle cell anæmia (Hb *S*) hæmoglobins, indicating that the difference between the two proteins was located there. I have now determined the chemical constitution of these No. 4 peptides derived from both hæmoglobin *A* and *S*.

The hæmoglobin *A* No. 4 peptide was prepared by elution from the neutral fraction of many 'finger-prints', followed by cooled paper electrophoresis in pyridine/acetic acid/water (*p*H 3·6 [2]) on Whatman No. 3 *MM* paper at 30 V./cm. for 75 min. The peptide was obtained as a well-separated band and eluted. The hæmoglobin *S* No. 4 peptide could be produced in a fairly pure state by eluting the slowest positively charged band from an extended one-dimensional paper electrophoresis of the peptide mixture in the *p*H 6·4 buffer[1]. In both cases qualitative amino-acid analysis by paper chromatography showed the presence of histidine, valine, leucine, threonine, proline, glutamic acid and lysine. There was more glutamic acid in the hæmoglobin *A* peptide, but more valine in the hæmoglobin *S* peptide. In view of the known specificity of trypsin[3], it was to be expected that these peptides, obtained by tryptic hydrolysis, had lysine at the C-terminal end. This agreed with all the results from the partial acid hydrolysis studies, as reported below.

Partial hydrolysis in 12 *N* hydrochloric acid at 37° C. for two or three days, followed by 'finger-printing'[1], gave the peptides indicated in Fig. 1, and

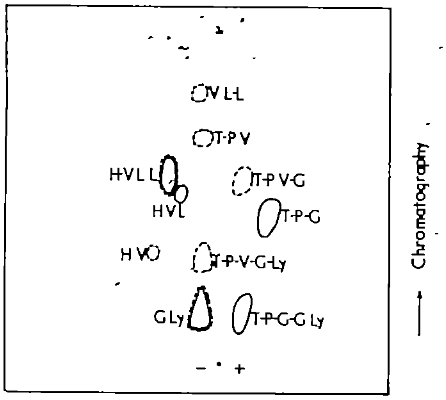

Fig. 1. Acid degradation and structure of the No. 4 peptides from hæmoglobins *A* and *S*. Hæmoglobin *A* (full lines): $\overset{++}{\text{His}}$—Val—Leu—Leu—Thr—Pro—$\overset{-}{\textit{Glu}}$—$\overset{-}{\text{Glu}}$—$\overset{+-}{\text{Lys}}$. Hæmoglobin *S* (broken lines): $\overset{+-}{\text{His}}$—Val—Leu—Leu—Thr—Pro—*Val*—$\overset{-}{\text{Glu}}$—$\overset{+-}{\text{Lys}}$

also free amino-acids, which are omitted from the figure. The N-terminal amino-acids of most of these peptides were determined by the fluoro-2,4-dinitrobenzene method[4]. Together with the amino-acid compositions, these fragments indicated the sequences of the No. 4 peptides of hæmoglobins *A* and *S* shown in Fig. 1. The only ambiguity was the amino-acid following threonine. Here the relevant products from the hydrochloric acid splitting—threonyl–prolyl–glutamyl–glutamyl–lysine and threonyl–prolyl–valyl–glutamyl–lysine—were subjected, on paper strips, to a stepwise Edman degradation for two cycles[4,5]. The results indicated the sequence threonyl–prolyl– in both cases. The charge distribution of the two No. 4 peptides shown in Fig. 1 was deduced from the electrophoretic behaviour of the two peptides, especially in relation to the behaviour of the smaller split peptides. The only difference found between the two No. 4 peptides is that the first glutamic acid residue of the hæmoglobin *A* peptide is replaced by valine in the hæmoglobin *S* peptide.

It is known from X-ray crystallographic[6] and from chemical[7] studies that the human hæmoglobin molecule of molecular weight 66,700 is composed of two identical half-molecules, each approximately 33,000. It is believed that this substitution, which occurs in each of the two identical half-molecules, constitutes the only chemical difference between normal and sickle cell anæmia hæmoglobins. Certainly the hæm groups of the two proteins are the same[8]. The fact that in each half-molecule a glutamic acid is replaced by the neutral amino-acid valine agrees with previous findings that the whole hæmoglobin *S* molecule has two to three carboxyl groups fewer than the normal protein[9,10]. All the other peptides of the tryptic digest occupy identical, and characteristic, positions in the two 'finger-prints'. Qualitative amino-acid analyses of these peptides have now been carried out, but have failed to reveal any differences between them. It would seem probable, therefore, that they have identical structures, leaving the two No. 4 peptides as the only ones that differ.

About 30 per cent of the hæmoglobin molecule is not susceptible to attack by trypsin and does not appear on the 'finger-print'. To eliminate the possibility that an additional difference resides in these large hæmoglobin *A* and *S* fragments, they were digested with chymotrypsin, which attacks them readily. Again two peptide mixtures were obtained, which were examined both by 'finger-printing' and by careful paper chromatography of the neutral peptides. No differences between them could be detected.

We owe to Pauling and his collaborators[9] the realization that sickle cell anæmia is an example of an inherited 'molecular disease' and that it is due to an alteration in the structure of a large protein molecule, an alteration leading to a protein which is by all criteria still a hæmoglobin. It is now clear that, per half-molecule of hæmoglobin, this change consists in a replacement of only one of nearly 300 amino-acids, namely, glutamic acid, by another, valine—a very small change indeed.

Differences between closely related proteins, involving only a very small number of amino-acids, are known; the clearest examples are the differences between horse, whale, sheep, pig and cattle insulins, which show changes in only one sequence of three amino-acids[11]. However, since these are inter-species differences, the genetic mechanism underlying them is by no means clear and cytoplasmic inheritance has not yet been ruled out. The abnormal human hæmoglobins, on the other hand, are a group of very closely related proteins within the same species. It is certain that the inheritance of these proteins is Mendelian in character and occurs through the chromosomal genes. Neel[12] has shown that a single mutational step of such a gene, the one responsible for making hæmoglobin, produces the new abnormal sickle cell anæmia hæmoglobin. Previous investigations on the normal and the sickle cell anæmia protein could not decide whether the difference between them is due to a difference in folding of identical polypeptide chains or to a difference in the amino-acid sequences of the two chains. While there may also be changes in folding, it has now been definitely established that the amino-acid sequences of the two proteins differ, and differ at only one point. Thus it can be seen that an alteration in a Mendelian gene causes an alteration in the amino-acid sequence of the corresponding polypeptide chain. In the case of sickle cell anæmia hæmoglobin, this is the smallest alteration possible—only one amino-acid is affected—reflecting, presumably, a change in a very small portion of the hæmoglobin gene. It is not known, but it may well be that this involves a replacement of no more than a single base-pair in the chain of the deoxyribonucleic acid of the gene.

It is well known that mutations lead to very small chemical differences between, for example, flower pigments[13]. It seems likely that these mutations produce first a change in a protein, in this case probably an enzyme, which in turn causes the production of a changed flower pigment. These enzymes, which have not yet been investigated for differences, stand in closer relationship to the gene than do the flower pigments themselves. The protein hæmoglobin is just as close. It has therefore been called the first gene product, and is probably the first protein to be made by the gene.

The divisibility of genes in a virus was shown previously in bacteriophage by Benzer[14] and Streisinger[15], who studied the effects of many different mutations of a gene on the behaviour of the virus. Such sub-units in genes have also been shown in *Aspergillus*[16] and *Neurospora*[17]. The results presented in this communication are certainly what one would expect on the basis of the widely accepted hypothesis of gene action; the sequence of base-pairs along the chain of nucleic acid provides the information which determines the sequence of amino-acids in the polypeptide chain for which the particular gene, or length of nucleic acid, is responsible. A substitution in the nucleic acids leads to a substitution in the polypeptide.

The abnormally low solubility of reduced hæmoglobin *S*, which causes the sickling of the erythrocytes in the anæmia, is presumably a function of the charge distribution on the surface of the molecule. The replacement of two charged glutamic acid residues for two uncharged valines is presumably enough to alter this distribution towards one favouring abnormally easy crystallization.

It is hoped that similar studies of other abnormal human hæmoglobins[16] will provide further insight into the effects of gene mutations.

Full details of this work will be published shortly elsewhere. I am indebted to Drs. S. Brenner and G. Seaman, Cambridge, for supplying blood from patients with homozygous sickle cell anæmia. It is a pleasure to acknowledge the constant interest and encouragement shown by Drs. M. F. Perutz and F. H. C. Crick. Some of the enzymatic digestion and 'finger-prints' were done by Mr. J. A. Hunt; Miss Rita Prior rendered invaluable assistance.

THE REPETITIVE PROPERTY OF THE HUMAN BRAIN AS STUDIED BY THE ELECTROENCEPHALOGRAM AND THE METHOD OF AFTER-IMAGES

By Dr. CATHERINE POPOV

Laboratoire du Conditionnement, Clinique Psychiatrique Infantile du Professeur Heuyer, Salpêtrière, Paris

THE study of electrocortical responses to different stimuli has allowed us to establish that a single stimulus of sufficient intensity not only provokes a simultaneous excitation, but also is followed by a series of later excitations which reappear spontaneously, without further stimulation, for several minutes. This phenomenon was called the 'repetitive property of the brain'[1,2].

Using various stimuli in experiments on man, we have likewise observed that a single stimulus evokes in consciousness not one but a set of sensory responses. In fact, a primary response which occurs simultaneously with the stimulus is later reproduced spontaneously a number of times, without further stimulation, thus forming a consecutive after-effect. In the case of stimulation by light, these phenomena are known as after-images; hitherto their appearance had been attributed to a retinal effect. We have proved, however, by conditioning these images, that they may be of central origin and that their spontaneous appearance is a phenomenon inherent in the functioning of the cerebral cortex[3].

The existence of the repetitive property of the brain seems to indicate, from all the evidence, that the sensation experienced is evoked by the simultaneous excitation, that is, the excitation which appears at the very moment of the stimulus. However, it seems probable that the overall sensation experienced is especially evoked by the excitation due to the consecutive after-effect. To elaborate the above phenomena, we have carried out experiments on the electroencephalogram using the following methods.

We selected subjects for study who showed well-defined alpha-waves, and stimuli were given only when alpha-waves appeared on the tracing. The subject is seated alone in a darkened room and receives stimuli controlled by an experimenter in another room which contains all the apparatus, and is separated from the dark room by a third intervening room. He is submitted to light-stimuli the intensity and character of which are kept constant throughout the experiments. Whenever the subject sees an after-image, he registers its appearance by pressing a rubber bulb, which records this event on the electroencephalogram tracing. After each sitting, the subject is asked to draw images in colour as he has seen them during the experiment.

With a normal subject, the light-stimulus evokes a series of after-images characteristic of the cortical response of the subject. Subjects who have been under observation for several years invariably draw the same series of images after each experiment. In some cases, a normal subject may have a consecutive after-effect which does not exceed 90 sec. (in one case, 58 sec.), and shows as few as four or five after-images. With other normal subjects, the number of after-images may exceed several dozen, and the consecutive after-effect may last 20, 30 or more minutes. We have not been so concerned with these latter subjects since the length of the consecutive after-effect does not allow us to give several light-stimuli in a single sitting. With all these subjects, electroencephalogram recordings have shown[3,4] that with the appearance of after-images there is a successive

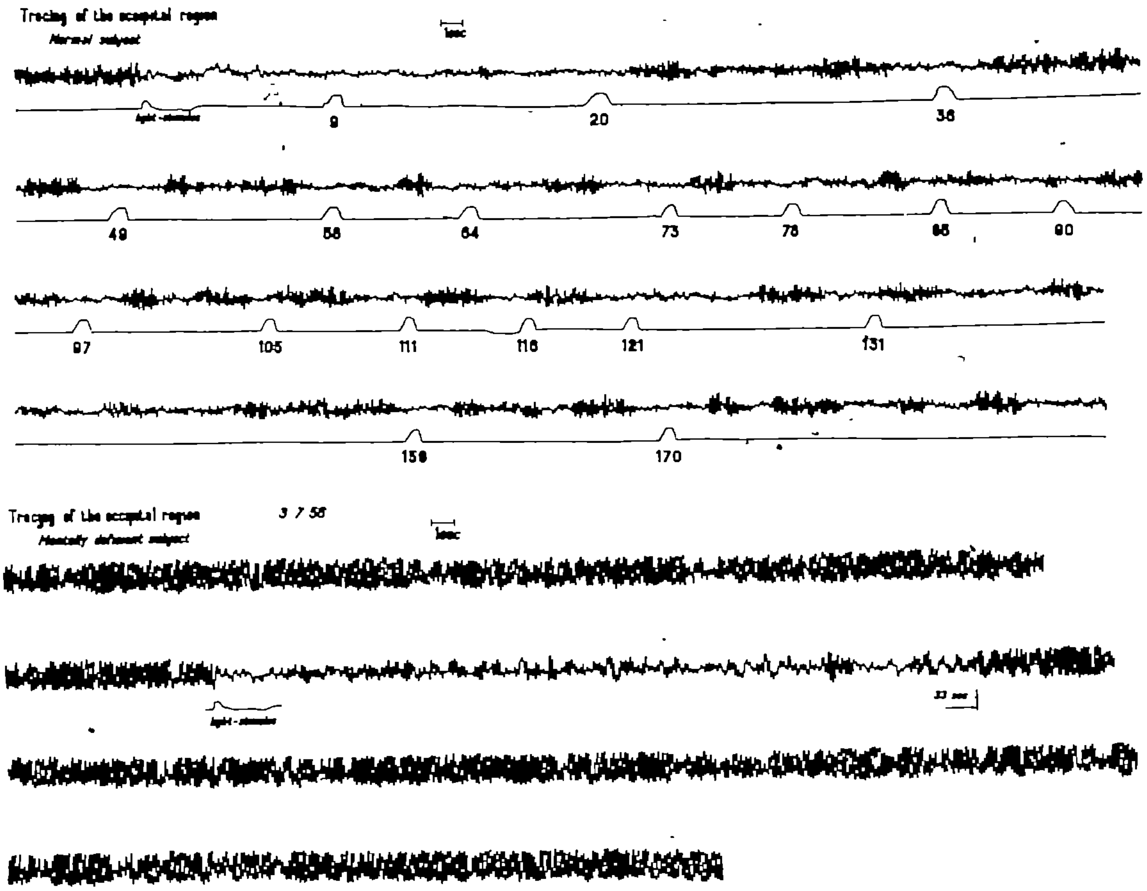

Fig. 1

reduction of alpha-waves, as seen in the tracing (see Fig. 1, upper traces).

In Prof. Heuyer's children's psychiatric clinic, we have used the above methods for studying the response of a number of mental patients. Among these there appeared a group which exhibited absence of after-images in experimental conditions in which a normal subject would see several dozen. In these subjects, the light-stimulus provokes a short after-effect which is manifested by a flattening of the tracings just after the light-stimulus, and lasts at most for 30–35 sec.; the tracing then returns to its original form, without showing the successive reductions well seen in the normal subject (see Fig. 1, lower traces). Thus, we may suppose that these subjects do not see after-images.

In all these cases, the subjects concerned exhibited mental deficiency. The term 'mental deficiency' is understood here in the limited sense of simple intellectual backwardness. Such patients present a number of well-defined characteristics:

(1) Clinically, they show great difficulty in solving a new problem, or in any kind of intellectual achievement; this is seen in the poor scholastic progress of the patient, and also by the slowness with which they acquire in childhood the basic achievements of early development (walking, speech, cleanliness). We have not dealt with subjects showing marked affective problems, or gross disturbance of behaviour.

(2) From the psychological point of view, the intelligence quotient varies between 55 and 80 (Wechsler–Bellevue).

(3) Etiologically, we have not dealt with subjects presenting marked pathological backgrounds (abnormal pregnancy, obstetrical shock, head injuries, previous trauma—infectious or toxic). We have frequently discovered the existence of mental deficiency in the patient's antecedents.

(4) From the point of view of the electroencephalogram, all subjects showed well-defined occipital alpha-waves. We do not suggest that this is an indispensable characteristic in the diagnosis of mental deficiency, but the presence of these well-defined alpha-waves seems to us to characterize a special group of mentally deficient subjects.

Thus, these experiments suggest that the repetitive property of the brain following light-stimulation does not show itself in the mentally deficient studied by me. I am far from wishing to suggest by this that the intelligence of a subject is in direct relation to this phenomenon. I merely think that the repetitive property of the brain is correlated with the degree of ability of the subject to experience the sensation; and clinically this characteristic tracing after light-stimulation has a practical application in that it allows us to distinguish this condition from other mental states.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Electrostatic Charges on Spores of Fungi in Air

PARTICLES or droplets suspended in air often carry an electrostatic charge. The size and magnitude of the charge depend on how the charge originates (commonly by picking up positive or negative ions from the air). The phenomenon appears to be fundamentally distinct from the characteristic positive or negative charges acquired by particles in colloidal solution[1]. Buller reported that spores of the common mushroom (*Agaricus campestris*) and the dryad's saddle (*Polyporus squamosus*) already carry either positive or negative charges when they are shed into the air by the fungus[2]. Ingold has recently suggested that in fungi with long, narrow, vertical hymenial tubes, such as *Ganoderma applanatum*, electrostatic forces may serve to keep a basidiospore in the middle of the tube while it is slowly falling under gravity to the exterior[3].

After a dozen tests made during 1954 and 1955 on naturally occurring specimens growing on trees, I can confirm the existence of such charges on the basidiospores of *Ganoderma applanatum*. Further, in this species most spores carry a positive charge.

Tests were made by allowing spores to fall in an air-gap between two metal plates charged from a battery. The apparatus (Fig. 1) consisted of a brass box in the form of a cube with approximately 2·5 cm. sides, and with a slit 0·5 cm. wide in the lid, placed immediately under an actively sporulating fruit body. The vertical charged metal plates, separated by an air-gap 1 cm. wide, were mounted on 'Perspex' blocks to insulate them from the walls of the box (which was earthed). The circuit was suggested to me in discussion by Mr. H. L. Nixon, of Rothamsted Experimental Station, and consisted of deaf-aid dry batteries giving in series about 400 volts, connected to the vertical plates through 680-kΩ resistors for safety. The poles of the battery were kept at +200 and −200 volts with respect to earth by earthing each end of the battery through 1·0-MΩ resistors.

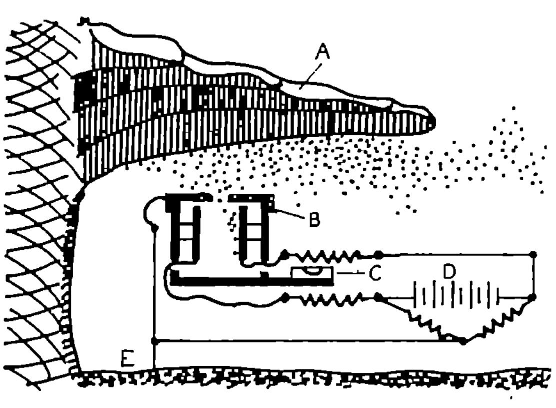

Fig. 1. Diagram (not to scale) *A*, Fruit body of *Ganoderma applanatum* (shown in vertical section) growing on tree trunk and liberating spores into air from vertical tubes; *B*, brass box with slit in lid, connected to earth and holding vertical insulated plates charged to +200 and −200 V.; *C*, bubble level; *D*, battery connected through resistors to plates and to earth; *E*, earth line to ground

In use, the box was levelled with a bubble level and exposed under an active fruit body of *Ganoderma applanatum*. After exposure for an hour, a rusty brown spore deposit was usually visible on the negatively charged plate and on the adjacent part of the base of the box, whereas the positive plate remained clean. In one test in which the box was taken apart and the spores counted under the microscope, 85 per cent of the spores entering the box had been deposited on the negative plate, 14 per cent were on the earthed floor of the box (mostly nearer the negative plate), and 1 per cent were on the positive plate. Essentially similar results with this species have been obtained at three localities in Hertfordshire, at one in the New Forest and at two in Bristol. In one of the Bristol specimens, the spores seemed to be less strongly charged than in other specimens. Some specimens have been tested on two or three occasions and in different years.

Because the majority of basidiospores move towards the negative plate, it is concluded that they carry a positive charge. Preliminary tests indicate that positive charges predominate also on basidiospores of *Agaricus campestris*, *Pholiota squarrosa* and *Flammula carbonaria*. On the other hand, negative charges seem to predominate on basidiospores of *Coprinus micaceus*, *C. hiascens* and *Polyporus squamosus*.

The phenomenon raises a number of problems. What is the origin of the charge? Does it differ consistently in different species? Why, if so nearly uniform in sign, as in *Ganoderma*, is it not completely uniform? Is it causally connected with the still mysterious spore discharge mechanism of basidiomycetes? Does it aid liberation of spores from the fruit body, as suggested by Ingold? Does it affect the pick-up of air-borne spores by rain drops, or their deposition on plant surfaces or in the respiratory tract of vertebrates?

Electron Microscopy of Leaf Surfaces

THE morphology of leaf surfaces is of considerable interest in the study of the effects of selective herbicides. In the course of investigation into the nature of some leaf surfaces, it was suspected that structure beyond the resolution of the light microscope was present. The electron microscope was therefore employed in an attempt to determine the nature of this structure. The examination of the surface of a leaf required the use of a replica technique, preferably not involving the treatment of the specimen with organic solvents, since many leaf surfaces are covered with a waxy layer which might be affected. A single-stage method involving evaporated material was therefore indicated, and though at first it seemed likely that any such method would meet with considerable difficulties, an extremely interesting technique was easily developed.

The method employs evaporated carbon[1], and is carried out as follows. A portion of the leaf to be examined is fixed to a glass slide with 'Sellotape', and the assembly placed in an evaporating plant. There

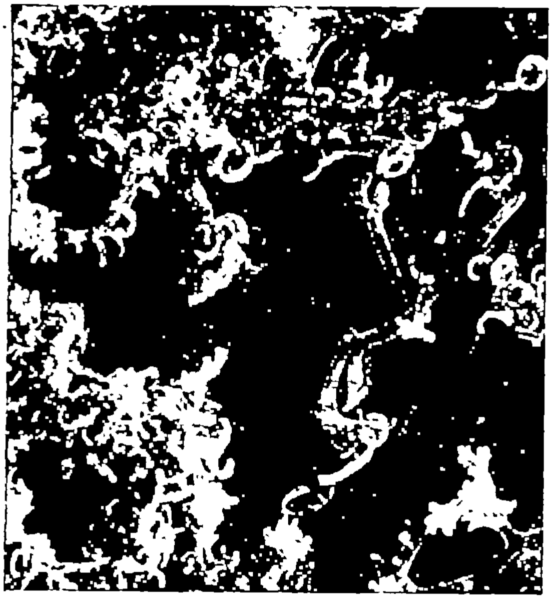

Fig. 1. Carbon replica of the adaxial surface of a leaf of *Chrysanthemum segetum*. × 11,000

is very little gassing, and a sufficiently good vacuum to allow the deposition of a carbon film can be obtained with normal pumping. The carbon evaporation is carried out by passing a heavy alternating current through the points of two carbon rods lightly pressed together. A film between 100 and 200 A. in thickness has been found satisfactory. The leaf is now removed from the vacuum and the carbon film dry-stripped from the surface by any of the normal methods. In many cases it has been found satisfactory to back the carbon with 'Formvar' and then 'Bedacryl', and finally strip the combined films from the leaf with 'Sellotape'. The 'Bedacryl' is dissolved from between the 'Formvar'-carbon film and the tape by immersion in acetone. The 'Formvar'-carbon films can then be mounted on grids and the 'Formvar' washed away with chloroform as described in detail elsewhere[2]. In other cases where the wax layer is excessively thick, it is helpful to freeze the specimen before stripping. The final replica is shadowed before examination in the electron microscope.

It is interesting to note that the leaf does not suffer a gross distortion in its morphology due to the escape of gas in the vacuum plant. The carbon film can be stripped without difficulty, directly from the surface, and this is thought to be due to the wax or cutin acting as a separating layer between the cellulose and the carbon film.

This technique provides, according to the nature of the leaf surface, either a true replica, or a pseudo-replica in which the surface protrusions remain embedded within the carbon film, having been torn off the original surface. Fig. 1 shows the adaxial surface of a leaf of *Chrysanthemum segetum*. There is a large number of branching tube-like structures on the surface, some of which are in the form of spirals, suggesting that they have been extruded. Measurements of contact angle on this leaf gave high values which could not be accounted for by any structure visible in the light microscope. It is thought that the submicroscopic structure found could account for this, especially as a leaf with a low contact angle, *Rumex obtusifolius*, showed a nearly smooth surface in the electron microscope. The replica shown is probably partially a pseudo-replica, that is, some of the protrusions have been dissolved from the carbon film during the replica process, the remainder being embedded in the replica.

Work along these lines is continuing, and will be published in greater detail elsewhere. One of us (D. E. B.) wishes to thank Dr. T. E. Allibone, director of the Research Laboratory, Associated Electrical Industries, for permission to publish this communication; the other (B. E. J.) would like to thank Imperial Chemical Industries, Ltd., for financial assistance in the above research.

Distortion of Fluid Drops in the Stokesian Region

IN an investigation of circulation inside drops moving in a viscous medium, the drop size has been varied in order to determine the factors affecting the minimum size at which circulation can be detected. With some systems, such as water drops in castor oil, circulation commences at a Reynolds number in the range 0·03–0·1 (drop diameter 10–20 mm.), whereas with other systems such as chloroform or carbon tetrachloride in glycerol, circulation begins at much lower Reynolds number of 0·0003–0·001 (drop diameter 1–3 mm.). The interfacial tensions of the two systems are not widely different.

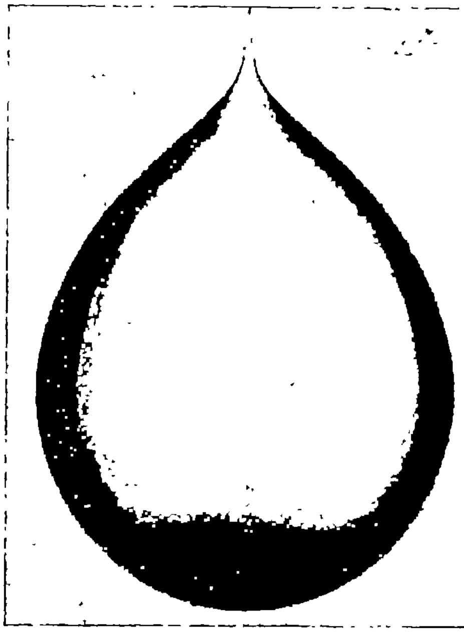

Fig. 1. Water drop falling in castor oil. Dia. = 2·29 cm., fall velocity = 0·87 cm./sec. Re. No. = 0·17

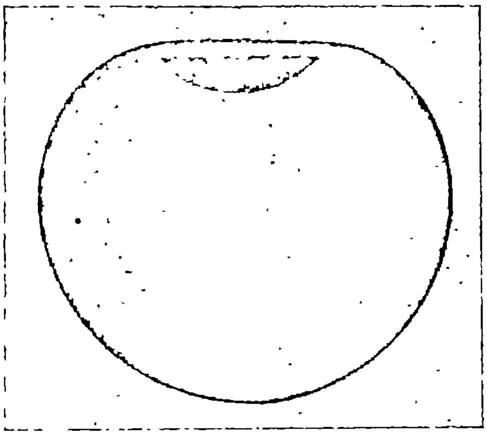

Fig. 2. Chloroform drop falling in glycerine. Dia = 2·22 cm., fall velocity = 4·36 cm./sec. Re. No. = 0·94

These two types of systems show different forms of drop distortion. For the first type, the drop assumes a 'tailing shape' at the onset of circulation (Fig. 1) and this shape has been observed earlier by Arnold[1]. Savic[2] has suggested that the viscous outward suction at the rear of the drop exceeds the tension in the interfacial layer and causes the surface layer to fold up.

With the second systems, as the size of the drop is increased, the drop remains spherical until the Reynolds number of about 0·1 is reached, when the upper surface of the drop begins to flatten out. For still higher Reynolds numbers, the upper surface folds inward causing an indentation or cavity at the top of the drop. This can be seen clearly in Fig. 2, which is a photograph of a drop of chloroform falling in glycerol. The horizontal line in the cavity is the far top edge of the drop, which is displaced downwards due to optical distortion caused by a slight difference in the refractive indices of the two phases. This form of distortion has not been reported in the past.

The distortion of drops in the Stokesian region depends on the relative changes in the outside hydrodynamic pressure and the inside pressure due to circulation. The circulation pressure comes into play when the drop changes from stagnant to circulating and increases thereafter with increasing Reynolds number. Now with the first systems, with relatively large stagnant drops, the hydrodynamic suction is high, so that a tail is formed before internal circulation is fully developed; this is in accordance with the explanation given by Savic[2]. With the other systems, where circulation begins at very low Reynolds number (less than 0·001) and with much smaller drops, the hydrodynamic suction is very low and there is no distortion. With increasing drop size, the outside hydrodynamic pressure and the inside circulation pressure change in accordance with the Hadamard[3] functions, so that the excess pressure (pressure inside minus pressure outside) remains equal to $2\gamma/a$, where γ is the interfacial tension and a is the local radius of curvature at the rear of the drop. However, at Reynolds numbers greater than about 0·1, the hydrodynamic pressure progressively increases over that indicated by the Hadamard function, and there is a decrease in the excess pressure $2\gamma/a$. Hence a, the radius of curvature at the rear stagnation point, must increase and the drop becomes increasingly flatter at the top. At Reynolds number greater than about 0·4, the excess pressure becomes negative, a assumes a negative value and the drop starts to cave in.

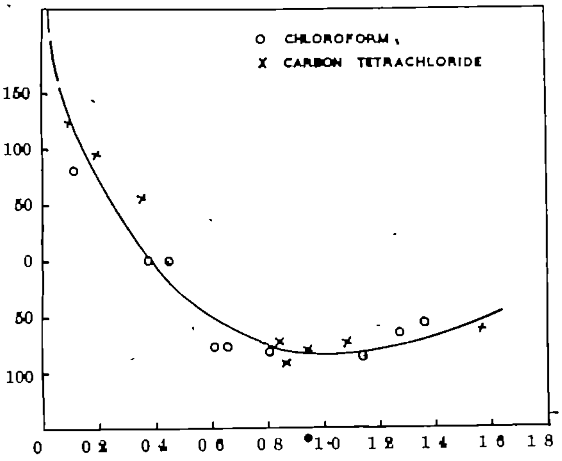

Fig. 3. Reynolds number vs. $2\gamma/a$. Continuous phase, glycerol

To check the validity of the preceding explanation, a series of photographs of carbon tetrachloride and chloroform drops falling through glycerol was taken, and the radius of curvature of the surface at the rear was measured from enlargements of the photographs. The Reynolds number for each drop was plotted against $2\gamma/a$ (Fig. 3). The results in glycerol fall on one curve. The value of $2\gamma/a$ is positive for small Reynolds numbers and decreases with increasing Reynolds number until it reaches zero at Reynolds number 0·4, when the drop begins to cave in; with further increase in Reynolds number, $2\gamma/a$ has a decreasing negative value and beyond Reynolds number 1·0 tends to rise.

A fuller account of this work will be published elsewhere.

Crystal Structures of Silicon Nitride

Vassiliou and Wilde[1] have recently reported a hexagonal silicon nitride, the X-ray diffraction pattern of which differs from that of the 'orthorhombic' silicon nitride extracted from silicon steels by Leslie, Carroll and Fisher[2]. After preliminary evidence of two different nitrides[3], Turkdogan, Bills and Tippett[4] have now definitely established the existence of two forms of silicon nitride, designated as α and β, with the same chemical compositions (Si_3N_4) and the same measured densities (3·19 ± 0·01 gm./ml.). Even more recently, the same two phases, I and II, as observed by Vassiliou and Wilde have been claimed by Popper and Ruddlesden[5] to be orthorhombic and rhombohedral respectively.

The results of an X-ray examination which we have made on α- and β-specimens prepared by

* Impurity. † β Impurity in α.

Turkdogan *et al.* seems to resolve some of the previous anomalies.

α-Si_3N_4 is hexagonal with dimensions: *a*, 7·748 ± 0·001 A.; *c*, 5·617 ± 0·001 A.; *c/a*, 0·7250; *V*, 292·0 A³. If the unit-cell contents are $Si_{12}N_{16}$, the calculated density (3·184 gm./ml.) is in good agreement with the measured density.

β-Si_3N_4 is also hexagonal with dimensions: *a*, 7·608 ± 0·001 A.; *c*, 2·9107 ± 0·0005 A.; *c/a*, 0·3826; *V*, 145·9 A³. If the β unit cell contains Si_6N_8, the calculated density (3·187 gm./ml.) and the observed density are again in excellent agreement. These data show that any difference between the chemical compositions of the two forms must be negligible.

Every reflexion observed on 19-cm. powder photographs taken with iron $K\alpha$ X-radiation has been indexed unequivocally. For example, of the forty-eight possible reflexions of the β-Si_3N_4 diffraction pattern, only five are too weak to be observed. As shown by Table 1, which lists only the first few interplanar spacings, the nitride reported by Vassiliou and Wilde is β-Si_3N_4, and the 'orthorhombic' phase found by Leslie *et al.* is undoubtedly α-Si_3N_4 containing small amounts of β and an unknown impurity.

A complete structure determination assigns β-Si_3N_4 to space group $P6_3/m$ with 2N in (*c*) at $\pm(\frac{1}{3}, \frac{2}{3}, \frac{1}{4})$, 6N in (*h*) at $\pm(x, y, \frac{1}{4})$; $\pm(\bar{y}, x-y, \frac{1}{4})$; $\pm(y-x, \bar{x}, \frac{1}{4})$, and with 6Si also in sites (*h*). The atomic parameters $x_N = 0{\cdot}333$, $y_N = 0{\cdot}033$, $x_{Si} = 0{\cdot}172$, and $y_{Si} = -0{\cdot}231$ are probably correct to within ±0·005, since the structure amplitude is sensitive to small atomic movements. The structure is based on the phenacite type[6], Be_2SiO_4, in which the oxygen atoms and the beryllium atoms are replaced respectively by nitrogen and silicon. Each silicon is at the centre of a slightly irregular tetrahedron of nitrogens, and the SiN_4 units are joined by sharing corners in such a way that each nitrogen is common to three tetrahedra. Alternatively, the structure may be considered as an arrangement of eight-membered Si_4N_4 puckered rings joined appropriately. The silicon–nitrogen interatomic distances are 1·72 A. and 1·75 A. Each of the two nitrogen atoms in positions (*c*) is at the centre of an equilateral triangle of silicons, and each nitrogen in (*h*) is displaced by about 0·1 A. from the plane of a less regular triangle of silicon atoms. The covalent bonding is clearly due to the overlap of each of four hybridized sp^3 silicon atomic orbitals with one singly-occupied sp^2 hybrid of a nitrogen atom. The remaining fully occupied *p* orbital of each nitrogen atom is perpendicular to the three planar sp^2 orbitals and cannot participate in bonding. The structure and the bonding are compatible with the observed high electrical resistivity[5].

The structure of α-Si_3N_4 (space group $P31c$) is a different arrangement of the same tetrahedral units as those which occur in β. Planes of atoms in β are linked along the [001] direction in a sequence *ABAB* . . ., whereas in α the sequence is *ABCDABCD*. . . .

We are indebted to Dr. E. T. Turkdogan, Mrs. P. M. Bills and Miss V. A. Tippett, of the British Iron and Steel Research Association, for providing samples of their α- and β-silicon nitrides and for discussion.

Properties of Palladium–Rhodium Alloys

AN earlier communication[1] from these laboratories gave preliminary results of an investigation into the magnetic susceptibilities of a series of palladium–rhodium alloys. A noteworthy finding was that alloying palladium with an element, rhodium, of a much lower susceptibility could, over a limited concentration-range, produce alloys having susceptibilities higher than those of either of the pure metals. This was more noticeable at low temperatures. More detailed investigations, since completed, have confirmed the general correctness of these results although minor adjustments of the absolute values previously given are required in some cases.

In addition to this more extensive investigation covering the magnetic properties of a range of alloys and pure metals, the low-temperature specific heats of four palladium–rhodium alloys have now been measured. The values of γ, the electronic heat coefficient, as obtained from measurements below 4·2° K., are shown as functions of the alloying metal content in Fig. 1. A few results for palladium–silver alloys[2] are also included to indicate the general trend of the curve on alloying with the element of next higher atomic number. For comparison the susceptibility–concentration curves have been drawn for palladium–rhodium and palladium–silver alloys at temperatures of 20·4° and 293° K.

The initial rise in the value of γ above that of pure palladium for small additions of rhodium, followed by the subsequent decrease as the rhodium content increases, is similar to the behaviour shown by the magnetic susceptibility, χ. It would be more illuminating to compare the γ values with the susceptibility values at 0° K.; this would, however, necessitate extrapolating downwards from 20·4° K. In view of the large curvature of some of the susceptibility–temperature curves at low temperatures it has not been considered justifiable to do this.

Although various explanations of the facts here reported are possible it is appropriate in this communication to refer only to the straightforward and consistent qualitative picture provided by the simple band theory, according to which the addition of rhodium creates more holes in the d-band while the addition of silver has the contrary effect. This interpretation does not, in its usual form, give a quantitative explanation of the results here presented. In particular, there is difficulty in reconciling the much larger relative increase in susceptibility at low temperatures with the small increase in electronic heat coefficient as small additions of rhodium are made to palladium. Changes in interaction effects with composition may probably be neglected as unlikely to produce considerable differential effects over small composition-ranges. Nevertheless, it is still not to be expected that the curves will be strictly parallel since γ depends essentially on the band height while the susceptibility depends upon both band height and curvature. In view of the gentle curvature of the γ-concentration curve, however, the difference in shape of the two susceptibility–concentration curves is greater than might be anticipated.

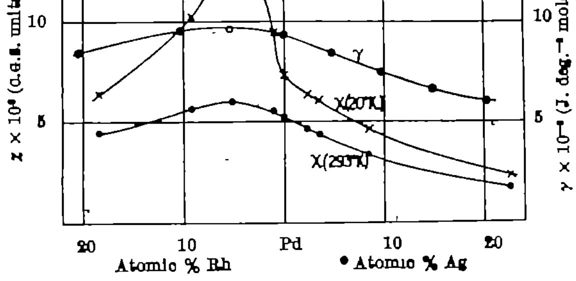

Fig. 1. Mass susceptibility, χ, and electronic heat coefficient, γ, for alloys of palladium with rhodium and silver

Attractive Forces between Flat Plates

SOME years ago investigations were carried out concerning attractive forces between glass and quartz bodies with flat polished surfaces[1]. Due to the well-known hygroscopic behaviour[2] of these surfaces, however, silica-gel obstacles were always present on the plates. These obstacles had a tendency to decrease the attractions and even to turn them into repulsions. Therefore metal plates have now been used instead of glass or quartz. The technique used was similar to that described earlier[1]. The main difficulties were caused by dust particles, and general agreement was found with the conclusions obtained in recent work[3] on the influence of dust particles on the contact of solids. Obstacles (smaller than 10μ) are distributed at random on the plates and show, especially in the case of aluminium plates, some 'compressibility'.

One of the plates could be moved by means of a lever system in a vertical direction towards, or away from, the other plate. This other plate was attached to a spring system. The lever system was checked by capacity measurements and showed a reproducible hysteresis behaviour, the loop-width of the hysteresis curve being 0·20–0·22 micron. This hysteresis behaviour was due to a knife-edge contact in the lever system. Knife-edge contacts, or in general frictional contacts, must therefore be avoided, unless under critical control. Once the properties of the lever system were known accurately, the distance between the metal plates during an experiment was easily calculated, provided the distance at the beginning of an experiment was known. This distance was about 5 microns and was conveniently varied between 2 and, say, 10 microns with an accuracy better than 0·01 micron. The ultimate attractive force K was measured by means of a capacity method.

The measurements, between two chromium plates or between two chromium–steel plates, indicate that Casimir's relation[4] $K = Ad^{-4}$, where d is the distance between the plates and K is the force per unit area of the metal surface, was not contradicted. The constant A was found to be 0·01–0·04 × 10^{-18} dynes cm.^{2}, whereas its theoretical value is 0·013 × 10^{-18} dynes cm.^{2}. The uncertainty was due to errors in the determination of the parallelism of the plates. The distance was varied between 0·3 micron and 2 microns. Surface asperities have so far prevented measurements between aluminium plates.

Pairs of plates of the same metal were chosen, because plates with different surface potentials attract each other according to $K_1 = 4·4 \times 10^{-5} P^2d^{-1}$, where P is the potential difference in millivolts, d is in microns and K_1 is in dynes cm.$^{-2}$. However, the potential difference P is never entirely zero, even if the same metals are used. The two plates were therefore insulated so that the time constant (RC) of discharge of the condenser formed by the two plates was much larger than one second (R being the resistance for charge carriers to come from one surface to the other, C being the capacity of the condenser). This meant that $R \gg 10^9$ ohm.

It may be remarked that already Lucretius[5] seems to have been acquainted with the phenomenon of two plates sticking together. Newton[6] carried out experiments on the adhesion of macroscopic bodies and distinguished between cohesive and gravitational forces.

Oxidation of Pentane in Mixtures with Air and the Negative Temperature Coefficient of Reaction

n-PENTANE in a chemically correct mixture with air was oxidized in a reactor formed by the annulus between concentric tubes of 'Vycor' (96 per cent silica). The inside diameter of the outer tube was 19 mm. and the outside diameter of the inner was 17 mm. Thus the annulus was 1·0 mm. wide. The reactor was supported concentrically in a vertical tubular electrical furnace 2 in. in diameter. The heated length of the furnace was 6¼ in. Temperature as measured on the exterior surface of the reactor attained a maximum value at approximately the mid-section of that length and was taken as related to rate of reaction and to the occurrence of ignition. Air plus the required concentration of pentane was supplied to the reactor at rates ranging from 50 c.c. to 400 c.c./min. Rates of reaction as based on oxygen consumption were determined by Orsat analysis of samples from the reactor effluent. Experimental results for rates of air supply decreasing by steps from 400 c.c. to 100 c.c./min. are given by the graphs of Fig. 1.

When the rate of air supply was 400 c.c./min., reaction did not begin at a measurable rate until the temperature was raised to 650° C. The rates of oxygen reacted and of the products formed as the temperature was further increased are shown by the relevant graphs of Fig. 1. It is to be noted that carbon monoxide was then formed, and at a greater rate than that of carbon dioxide, and that ignition occurred at 747° C. The characteristics of the high-temperature reaction, including the ignition temperature as given by the graphs of Fig. 1, remained substantially unchanged as rates of air supply were decreased to 100 c.c./min. When the rate of air supply was reduced to 200 c.c./min., reaction began at 420° C. and the rate of oxygen reacted increased to a maximum of 0·15 mole per mole of pentane at 470° C. The temperature coefficient then became negative and reaction-rate became zero at 505° C. Reaction did not begin again until the temperature was raised to 650° C., that is, the low- and high-temperature reactions were separated by a temperature interval of 145° C. during which rate of reaction was inappreciable. As rate of air supply was reduced to 150 c.c. and then to 100 c.c./min. the maximum rate of the low-temperature reaction increased while the temperature interval over which there was no appreciable reaction diminished, as shown by the graphs of Fig. 1. The products of the low-temperature reaction were aldehydes, acids, and water. There was no carbon monoxide or dioxide.

The experimental results obtained when the rate of air supply was reduced to 50 c.c./min. are given by the graphs of Fig. 2. It will be seen by a comparison with those of Fig. 1 that reaction began at a lower temperature, coincident with the formation of carbon dioxide, and a few degrees higher with that of carbon monoxide. The low- and high-temperature reactions were not separated by a temperature-range of no reaction. Ignition did not occur, although the temperature was raised to 800° C., the limit of the method of measurement. However, at that temperature 5·75 moles of the 8·0 moles of oxygen in the correct mixture had reacted and the products

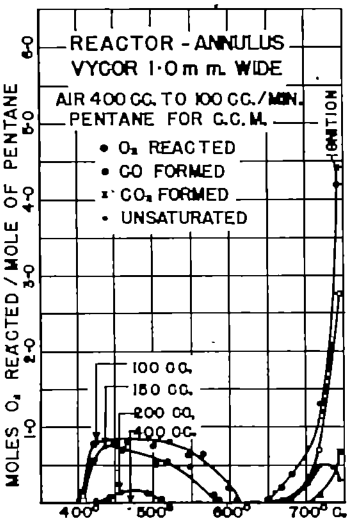

Fig. 1

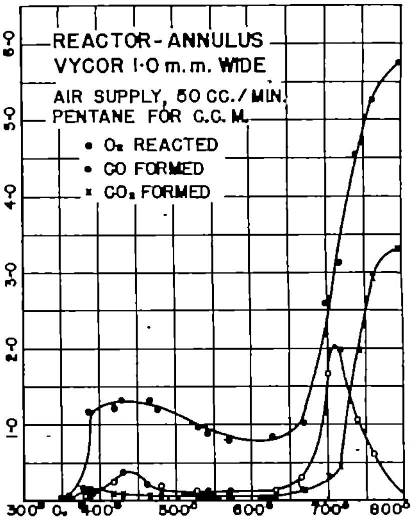

Fig. 2

of the oxidation reaction were carbon dioxide and steam only.

According to Reynolds numbers, the reacting mixture flowing through the reactor comprised a laminar stream with a parabolic velocity profile, bounded by stationary surface layers. Continuance of the oxidation of the surface layers would depend upon the release of the reaction products from the surfaces, their diffusion into the moving stream and diffusion of unreacted mixture from the moving stream to the surfaces. Thus, reaction velocity in the low-temperature region in which aldehydes and acids are principal products varies with residence time. It is in this region that a negative temperature coefficient of reaction occurs. The experimental results show it to be a surface phenomenon. It is therefore not necessary to account for it by devising a gas-phase reaction mechanism or by making use of any of those devised by others.

A comprehensive description of the experiments described and of others omitted for the sake of brevity, together with a more complete discussion of the experimental results, will in due course be published in a Canadian journal.

The experiments were carried out in the Department of Chemical Engineering, University of Toronto, with the co-operation of Prof. R. R. McLaughlin, head of the Department and dean of the Faculty of Applied Science, and with the aid of an extra-mural grant from the Defence Research Board, Ottawa.

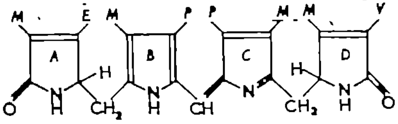
Structure of *d*-Urobilin

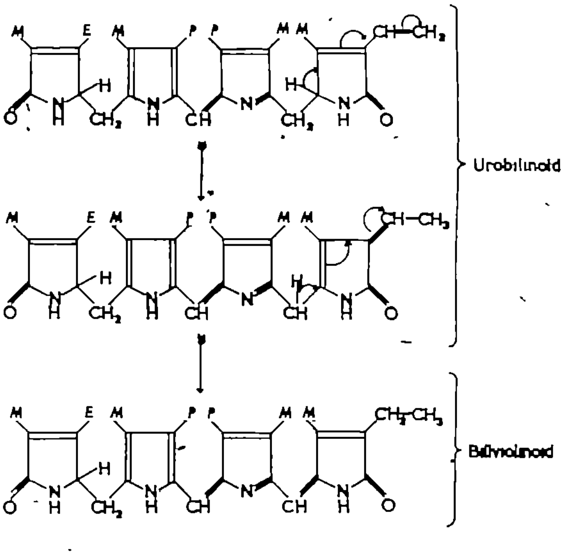
IN man the reduction of bilirubin by the intestinal bacteria normally leads to the formation of *i*-urobilinogen and stercobilinogen, which are excreted partly as such and partly as *i*-urobilin and laevo-rotatory stercobilin respectively. Broad-spectrum antibiotic therapy modifies the intestinal flora and unchanged bilirubin is then excreted. Upon withdrawal of this therapy, the alimentary canal again acquires reducing bacteria, and there is temporarily excreted a dextro-rotatory pigment (*d*-urobilin) which, although urobilinoid in its physical and chemical properties, is not an enantiomorph of stercobilin[1]. *d*-Urobilin has been shown to be isomeric with mesobilirubin and mesobiliviolin ($C_{33}H_{40}N_4O_6$) and is readily reduced, catalytically or by sodium amalgam, to mesobilirubinogen. The pigment is thus established as a IXα tetrapyrrolic structure and since the spectral properties closely resemble those of *i*-urobilin and stercobilin the compound must also contain the dipyrryl-methene chromophore characteristic of the urobilins. *d*-Urobilin is a labile pigment except when pure, and can therefore be obtained only in small quantities; this fact has hitherto precluded its investigation by degradation methods.

Recently, a human subject suffering from thalassæmia—a disease characterized by the presence of an abnormal hæmoglobin—who has not received antibiotic therapy, has been found to excrete large quantities of a pigment ($[\alpha]^{D}_{\text{chloroform}} = +4{,}520$–$+4{,}700$ for the hydrochloride) which resembles *d*-urobilin in every respect. On oxidation with 0·74 *N* chromic acid, 34 per cent of the nitrogen was converted to ammonia or a labile amine, indicating extensive destruction of the pyrrole rings. Paper chromatography of the other products clearly revealed the presence of hæmatinimide, succinic acid and methylethylmaleimide. The last two substances have been isolated in crystalline form and identified by melting point and mixed melting point determinations. The hæmatinimide would be expected to arise from the β-methyl β′-carboxyethylpyrrole nuclei, the further degradation of which probably accounts for the production of the succinic acid. The occurrence of the methylethylmaleimide proves the presence of a β-methyl-β′-ethylpyrrole ring, but only one such ring can be present in the molecule of *d*-urobilin. The pigment is certainly a dehydro-*i*-urobilin and the additional unsaturation must be located in the β-side-chains rather than elsewhere in the molecule, where its presence would be inconsistent with the presence of the dipyrryl-methene chromophore. Acrylic acid- and ethylidene-groups are, as yet, unknown in the bile pigments, and A. J. Birch, B. R. Smith and G. F. Smith (private communication) have proved the absence of the latter in *d*-urobilin. We therefore suggest the following structure for *d*-urobilin:



where $M = —CH_3$; $P = —CH_2CH_2COOH$; $E = —CH_2CH_3$; $V = —CH{=}CH_2$.

This structure takes into account the ketopyrroline forms known to predominate in the so-called 'hydroxy-pyrroles'[2] and in the urobilins (Birch *et al.* above) and is one of the two isomers formally possible by interchange of the ethyl- and vinyl-groups. In accordance with this formulation a sample of the hydrochloride ($[\alpha]^{D}_{\text{chloroform}} = +4{,}700$) in methyl alcohol absorbed a quantity of hydrogen approximately consistent with the presence of two centres of unsaturation.



Both *i*-urobilin and *d*-urobilin are readily dehydrogenated by ferric chloride to give biliviolinoid pigments, but with *d*-urobilin this change can be effected even in a reducing environment (lithium aluminium hydride in tetrahydrofuran). This observation supports the above structure for *d*-urobilin since the conjugated system of double bonds shown in ring *D* would impart considerable tautomeric lability to the hydrogen atom attached to the α-carbon atom, and simple isomerism (involving neither oxidation nor reduction) to a biliviolin is therefore formally possible.

Inhibition of Adrenal 11β-Hydroxylation by Ions

Hydroxylation of the 11-position of the steroid nucleus is an essential step in the biosynthesis of the physiologically active adrenal corticoids, cortisol and aldosterone. Previous investigations[1-3] have shown that the reaction is rather involved, requiring the participation of a reducing agent (reduced triphosphopyridine nucleotide), molecular oxygen and several enzymes.

In the present study, the latter were extracted from acetone powders prepared from bovine or porcine adrenal mitochondria, and hydroxylating activity was assayed fluorimetrically, as described earlier[3]. During attempts to fractionate the adrenal extracts with ammonium sulphate and other salts, it was observed that these substances strongly inhibited the 11β-hydroxylation of either 11-deoxycorticosterone or 17-hydroxycorticosterone (compound *S*). Further study indicated that a large series of inorganic ions (sodium sulphate, sodium chloride, potassium chloride, calcium chloride, dipotassium hydrogen phosphate, magnesium chloride, lithium sulphate) was capable of inhibiting the hydroxylation reaction.

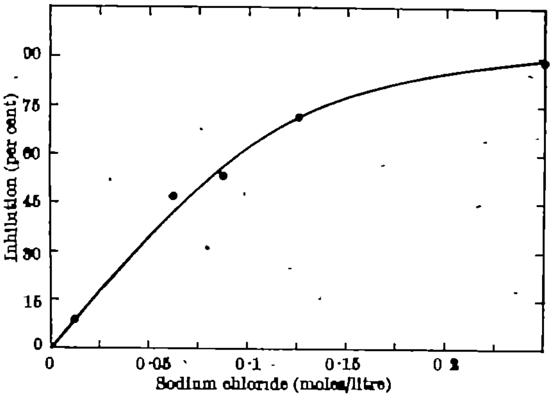

Fig. 1. The reaction mixture contained reduced triphosphopyridine nucleotide, 0·2 μmole; deoxycorticosterone, 0·058 μmole; *tris*(hydroxymethyl)aminomethane buffer, pH 7·4, 8 μmoles; enzyme; and added salt as indicated, in a volume of 1·0 ml. 10 min. incubation at 37° C. in air

In Fig. 1, which illustrates this phenomenon when sodium chloride was the inhibitor, it can be seen that inhibition of corticosterone formation from 11-deoxycorticosterone was proportional to the concentration of added salt. A similar inhibitory action of ions has been observed previously with glutamic dehydrogenase[4], and other enzymes.

Although current physiological evidence[5] suggests that intracellular ionic strength is not a primary factor in the regulation of adrenal steroid output, the observation presented here seems of particular interest since the adrenal cortex, by virtue of its ability to synthesize 11-hydroxylated salt-retaining hormones, is, in part, responsible for the maintenance of a constant ionic environment *in vivo*.

Composition of the Cell Wall of *Lactobacillus bifidus*

Analyses of hydrolysates of cell walls from a large number of different Gram-positive bacteria led to the suggestion that the chemical composition of bacterial cell walls may be a valuable taxonomic character. In general, the particular amino-acids present in the cell wall appeared to be characteristic of the genus, while specific and to a lesser extent strain differences were reflected in the type and relative amounts of the sugars and hexosamines present[1].

We have recently examined the cell-wall compositions of eight strains of *Lactobacillus bifidus*. The results are of interest both because they may throw some light on the taxonomic position of *L. bifidus*, and because they reveal an unusual degree of variation among different strains of what is thought to be a single bacterial species.

The strains investigated were some of those which had previously been examined by Hayward, Hale and Bisset[2], and we are indebted to these workers for making them available to us. For examination, the organisms were grown in tomato-juice broth[2] at 37° C., in an atmosphere of hydrogen plus 10 per cent carbon dioxide. After 2–4 days growth the cultures were killed by the addition of formalin, and the washed suspensions disintegrated in a Mickle shaker. Purified cell walls were prepared by digesting the insoluble fraction with trypsin and pepsin[1], and samples were hydrolysed at 100° C. in 2 *N* sulphuric acid for 2 hr. (sugars) or 6 *N* hydrochloric acid for 8 hr. (amino-acids).

The results of analysis by paper chromatography of hydrolysates of the cell walls of these strains are shown in Tables 1 and 2. In recording the amino-acids (Table 1) trace amounts have been ignored to avoid undue complication of the table. Alanine, glutamic acid and lysine were present in fractions from all strains, as were glucosamine and the amino-

sugar which we had previously referred to as 'unknown hexosamine', but which has now been identified by Strange[4] as 3-O-α-carboxyethylhexosamine, for which the name 'muramic acid' has been suggested[5]. Besides these components which were constantly present, however, there were others which showed an interesting degree of variation. Either one or two, but not more, of the amino-acids serine, glycine, threonine and aspartic acid were present in significant quantities. There was also considerable variation in the hexoses present, but rhamnose appeared to be either present in fairly large amount or else virtually absent (Table 2). If we consider only the different combinations of amino-acids, it is possible to distinguish four different patterns of components in the cell walls of these eight strains—a surprisingly high degree of variation in so small a series, and quite unlike anything we have previously encountered. The acid-resistant peptide of lysine and aspartic acid previously noted in cell wall hydrolysates from lactobacilli[1], which is identical with that found in acid hydrolysates of bacitracin[6], was not present in those strains of *L. bifidus* which contain aspartic acid (*HX* and *CN*, Table 1). This suggests that their cell walls are structurally different from those of other lactobacilli in which these amino-acids occur.

The taxonomic position of *L. bifidus* is somewhat uncertain, since it differs considerably in morphology from other lactobacilli, and it has been suggested that it is a corynebacterium, or that it is related to the Actinomycetales. As far as cell-wall composition is concerned, these eight strains do not correspond to any group of Gram-positive organisms previously examined. It seems very unlikely that they belong in *Corynebacterium*, since members of this genus have a cell-wall composition distinguished by the presence of arabinose and α,ε-diaminopimelic acid, neither of which was found in the present strains, and they do not resemble any of the groups so far found in Actinomycetales[7]. On the other hand, it has been reported by several workers[8] that, on repeated subculture, strains of *L. bifidus* become tolerant of oxygen and alter in morphology to a straight rod, resembling other lactobacilli. It seems possible, therefore, that strains of *L. bifidus* are in an unstable state and that the change to 'straight-rod' morphology and oxygen-tolerance might be accompanied by a change in cell-wall structure to that of other lactobacilli, but this point remains to be investigated.

We would like to thank Miss Sylvia Start for considerable technical assistance.

Cell-Wall Amino-Acids and Amino-Sugars

Studies of the chemistry of cell walls of many Gram-positive bacteria have established that they possess distinctive properties; indeed, a number of the uncommon constituents of bacterial cells have been found to be localized in the walls, for example, αε-diaminopimelic acid, D-isomers of amino-acids, and the sugars D-arabinose and rhamnose[1–4]. Cell-wall peptides are composed of a small variety of amino-acids and as few as three or four different amino-acids may account for most of the peptide[2,3]. Amino-sugars form important constituents of the cell-wall muco-complex substances, and the amino-sugar isolated in a crystalline form by Strange and Dark[4] has been shown to be a characteristic component of the walls of spores and Gram-positive bacteria[3,4].

The walls of several lactic acid bacteria were found to contain the D-isomers of alanine and glutamic acid by Ikawa and Snell[5]. A survey of the distribution of D-alanine and the detection of D-glutamic acid in the walls of several species have now shown that the occurrence of the D-isomers of these amino-acids is by no means confined to any one group and may constitute a more general feature of cell-wall composition. For qualitative demonstration of D-alanine in bacterial walls, cell-wall hydrolysates (6 *N* hydrochloric acid, 16 hr. at 107° C.)

were subjected to chromatography and the chromatograms sprayed with solutions of D-amino-acid oxidase (sheep kidney cortex); the pyruvic acid formed from the D-alanine was detected with the 2 : 4-dinitrophenylhydrazine spray reagent[5]. Heavy spots corresponding to alanine were obtained, thus indicating the presence of substantial quantities of D-alanine in the cell walls of *Staphylococcus aureus*, *Sporosarcina ureae*, *Sarcina lutea*, *Micrococcus lysodeikticus*, *Bacillus megaterium*, *Bacillus subtilis* and *Clostridium welchii*. Only a weak spot was given with a hydrolysate of *Rhodospirillum rubrum* cell walls. The occurrence of D-glutamic acid in the walls of several of these organisms has been established by separation of the glutamic acid from other cell-wall amino-acids and amino-sugars by paper electrophoresis (Whatman 3*MM* paper, pyridine/acetic acid buffer *p*H 6·4, 220 V. d.c.), colorimetric determination of the total glutamic acid by ninhydrin reaction and estimation of the L-glutamic acid with the decarboxylase method of Gale[6]. Only glutamic acid was detectable in the acidic fractions separable by electrophoresis of hydrolysates of *M. lysodeikticus*, *B. megaterium* and *S. lutea* walls. Apparently all the 6 per cent glutamic acid content of the walls of *M. lysodeikticus* is the D-isomer; as much as 50 mgm. of hydrolysed wall gave no detectable L-glutamic acid when assayed with the decarboxylase. A high proportion of the glutamic acid in *B. megaterium* wall is the D-isomer (total glutamic acid 4·5 per cent, L-glutamic acid 0·5 per cent); the walls of *S. lutea*, on the other hand, contained 4·2 per cent L-glutamic acid.

Diaminopimelic acid isomers present in cell walls have been investigated with the solvent system used by Hoare and Work[7]. The *meso*-isomer was found in the walls of *Escherichia coli* B, *Rhodospirillum rubrum*, *Chlorobium thiosulphatophilum*, *Micrococcus varians* and in a Gram-negative coccus (*LC*) isolated from the rumen of sheep[8]. Walls of *B. megaterium KM* contained mostly *meso*-diaminopimelic acid, but some LL-isomer was also detectable. Only the LL-isomer of this amino-acid was found in the walls of *Cl. welchii*. These results are in complete agreement with those of Hoare and Work[7] on the distribution of the isomers in intact bacteria.

The amino-sugar isolated by Strange and Dark[4] has so far been found in spore peptides and spore walls, the walls of various Gram-positive bacteria[2] and more recently in the nucleotide complexes of *Staphylococcus aureus* studied by Park and Strominger[9]. This amino-acid together with glucosamine has now been detected in the walls of a number of Gram-negative bacteria, including *Esch. coli* B, *Spirillum serpens*, *Salmonella gallinarum* and the Gram-negative coccus, *LC*. Cell walls of the photosynthetic bacteria *Chlorobium thiosulphatophilum* and *R. rubrum* contained both glucosamine and the amino-sugar described by Strange and Dark[4], although in the walls of the latter organism only a small amount of the amino-sugar was detectable. The method used for distinguishing the new amino-sugar from glucosamine or galactosamine involved the separation of 6 *N* hydrochloric acid hydrolysates on two-dimensional chromatograms and examination of the products formed from the reaction of the amino-sugars with ninhydrin[10].

Although the cell walls of Gram-positive and Gram-negative bacteria have a number of amino-acid and amino-sugar constituents in common, the composition of the walls of the Gram-negative organisms shows a greater complexity[1]. This has now been further illustrated by examining the products of the reaction of trypsin-treated walls with 1-fluoro-2 : 4-dinitrobenzene as described by Ingram and Salton[11]. Alanine and glycine were found to be the N-terminal amino-acids common to the cell walls of a number of Gram-negative species, including *Esch. coli* B, *Sp. serpens*, *R. rubrum* and the rumen coccus, *LC*. In addition, some of the walls also possessed aspartic and glutamic acids as N-terminal amino-acids. Whether all these proteins with different N-terminal groups form part of the essential framework of the cell wall or whether they represent proteins of different surface antigens or intracellular components adhering to the walls must await further studies.

Coxo-Subalar Muscle in the Mesothorax of Diptera

Two types of muscle are recognized in the mesothorax of Diptera: first, the large specialized dorsal longitudinal and dorsoventral indirect-flight muscles; secondly, the less specialized muscles that operate the legs and the pleural or so-called direct-wing, or direct-flight, muscles[1-4]. The indirect-flight muscles are described as of a fibrous or fibrillar nature, give a twitch response to stimuli and develop the extremely rapid thoracic vibrations that produce the main flight movements of the wings in Diptera (and Hymenoptera). The second group of less specialized muscles are described as of a tubular nature and give a tetanic response to stimuli; those connected with the wing base are presumed to set the wings and so be responsible for variations in the actual mode of flying.

Partmann[5] directed attention to anatomical peculiarities of the indirect-flight muscles; later, Tiegs[6] showed that the large muscle blocks which Partmann had discussed were giant fibres and not specialized bundles of fibres. Tiegs[6] pointed out that a so-called coxo-subalar muscle running from the meron of the meso-coxa to the subalar sclerite was present in Tipulids, Culicids and Chironomids and absent in such non-nematocerous Diptera as he had examined.

Tiegs[6] and others have assumed that this coxo-subalar muscle was of a nature similar to the other direct-wing muscles associated with the wing-base, namely, of the tubular type.

I have recently been surveying the Diptera generally in respect of the presence or absence of the mesothoracic tergal depressor of the trochanter muscle[7] and have been examining the mesothoracic musculature of *Anisopus* (Anisopidae (= Rhyphidae), Dipt.) in particular. I find that the coxo-subalar muscle is of the fibrillar type and not of the tubular type (Fig. 1), and consists, in *Anisopus*, of two giant fibres.

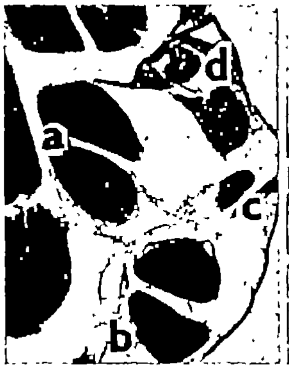

Fig. 1

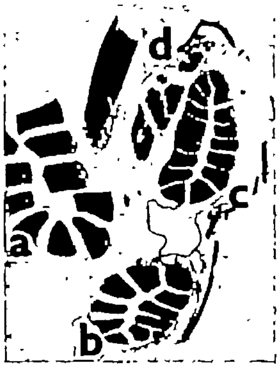

Fig. 2

Fig. 1. *Anisopus*. Part of approximately horizontal section of mesothorax with two-fibred coxo-subalar muscle cut transversely. Other indirect (fibrillar) flight muscles and direct (tubular) wing muscles can be seen in approximately transverse section

In both Figs. 1 and 2 *a* is second dorsoventral, indirect-flight, muscle; *b*, oblique, longitudinal, indirect-flight, muscle; *c*, coxo-subalar muscle, *d*, pleural, direct-wing muscles

Fig. 2. *Ptychoptera*. Part of approximately horizontal section of mesothorax with 17-fibred coxo-subalar muscle cut transversely

Examination of some other nematocerous Diptera shows that in their case also the coxo-subalar muscle is of the giant fibre type, the number of fibres being several, if the large indirect-flight muscles are of the multiple type, or few if the indirect-flight muscles, as in *Anisopus*, are of the few-fibre type. Fig. 2 shows the coxo-subalar muscle in *Ptychoptera* (Ptychopteridae (=Liriopedae), Dipt.), in which this muscle is especially large, consisting of some 17 fibres.

This specialized mesothoracic coxo-subalar muscle presumably serves some special function in the flight of these Nematocerous Diptera.

Reinterpretation of some Basal Structures in the Insect Ovipositor

SNODGRASS[1] based his interpretation of the female genitalia of the higher insect orders on the condition in Machilidae. In this family the ovipositor on the eighth and ninth segments is derived from the limb bases. The limb bases of the eighth segment (first genital) may be termed the first gonocoxae (1Gx) with the styli, the first gonostyli (1Gs) and the appendages, the first gonapophyses (1Gpo). Similarly, the ninth segment bears the second gonocoxae (2Gx), second gonostyli (2Gs) and second gonapophyses (2Gpo).

In the silver fish (*Lepisma*) and the fire brat (*Thermobia*) (Fig. 1*a*) there is a triangular-shaped sclerite which is fused to the base of the first gonapophysis and articulates with the ninth tergum (T9) and the second gonocoxa. This sclerite is absent as such in Machilidae (*Petrobius*). In *Thermobia* it is not attached to the base of the second gonapophysis as stated by Snodgrass[1]. Since Snodgrass misinterpreted the genitalia of *Thermobia*, he was unable to homologize the condition in that genus with that in the higher insect orders. I find that a more satisfactory interpretation is obtained if the structure in Lepismidae is taken as the archaic type from which the pterygote ovipositor was derived.

In most insect orders the gonostyli are lost in the adult and there is a sclerotic connexion between the base of the first gonapophysis and the ninth tergum. This connexion has been variously interpreted as the first gonocoxa, part of the second gonocoxa or outgrowths of the ninth tergum and the first gonapophysis. It is, in fact, the triangular-shaped sclerite variously modified (Scudder, unpublished work). A study of the abdominal musculature of *Petrobius* and *Lepisma* and the development of the female genitalia in the cricket (*Acheta*) shows that the triangular-shaped sclerite, which I term the gonangulum (Ga), is homologous with the antero-dorsal corner of the limb base of the ninth segment.

In Odonata the archetypal condition is retained in its entirety. The first gonocoxa has previously been termed the basivalvula, and the gonangulum, the valvifer[2]. In Hymenoptera (Fig. 1*b*), the gonangulum, previously interpreted as the first gonocoxa (=first valvifer or triangular plate), retains the triangular shape and attachments. The first gonocoxa is absent in this order. In the orthopteroid orders (Fig. 1*c*), the first gonocoxa and gonangulum fuse to form a composite sclerite. In *Grylloblatta*, however, the two structures remain separate. As in Odonata, in *Grylloblatta* the first gonocoxa has been termed the basivalvula, and the gonangulum, the first gonocoxa[4]. In the hemipteroid orders (Fig. 1*d*), the gonangulum is posteriorly fused to the ninth tergum, but the second gonocoxa still articulates to its ventro-posterior angle.

Ontogenetical studies show that the posterior outgrowths of the second gonocoxae, which develop into what Snodgrass called the third valvulae, are not homologous with the styli of the limb bases of the ninth segment. The term gonostylus, suggested by Michener[5], is therefore inappropriate. The term gonoplac is suggested as a substitute.

Development of Beet Eelworm, *Heterodera schachtii* Schmidt, in the Wild Beet, *Beta patellaris*

Observations made by Hijner[1] suggest that, while the roots of the resistant species of wild beet, *Beta patellaris*, are invaded by larvæ of the beet eelworm, *Heterodera schachtii*, no further development occurs beyond an early larval stage.

It has now been found that not only do a large proportion of the larvæ which enter the roots of *B. patellaris* develop to the intermediate or third larval stage, but also that a small percentage develop to maturity, becoming males. This was shown by growing plants singly in 2½-in. pots and adding 2,000 larvæ, hatched from cysts in sugar beet root diffusate, to each pot. The plants were then left for periods of from one to six weeks after the addition of larvæ, there being four plants in each group, making twenty-four plants in all. The roots of each plant were examined for larval stages of the parasite by the usual process of staining in boiling acid–fuchsin, weighing the stained root system and macerating in a domestic blender. The contents of the blender were then washed thoroughly through a 60-mesh sieve and aliquots placed in ringed Petri dishes, when the larvæ were counted under a binocular microscope.

It was found that about 15 per cent of the larvæ added invaded the roots and that, of these, about 65 per cent developed to the intermediate stage and about 7 per cent reached maturity. Even at the end of the six-week period no mature females were found, nor any immature individuals which could with certainty be identified as female. The remaining 35 per cent of the invading second-stage larvæ were either present in a deteriorated condition in the roots or had disappeared. This was also so with the majority of the intermediates.

This state of affairs appears to be a very close parallel to the pattern of development shown by Jones[2] to occur with the potato root eelworm, *Heterodera rostochiensis* Woll., in the wild potato, *Solanum tuberosum* sub sp. *andigena*, where, however, a few females have been found to develop also. It is possible that in further investigations this may also be found to be true of *Beta patellaris*.

I should like to thank Mr. F. G. W. Jones for his advice and also Miss M. Wolfe for technical assistance. I am indebted to the Sugar Beet Research and Education Committee for providing the facilities for carrying out this work.

Diego Blood Group in Negro

Among the various blood groups employed in anthropology, the Diego is one of the most peculiar to the study of human races.

In Negroes, hitherto the only reference has been the initial paper by Layrisse, Arends and Sisco[1], who found among 150 mixed Negroes that 7·3 per cent had the Diego antigen; but they emphasized the Indian mixture in their stock. We have had the opportunity of testing 120 pure Negro donors of the Instituto de Hematologia da P.D.F., with negative results. The anti-globulin method was employed, with anti-Diego serum, available from Dr. Layrisse.

We believe these results show that the Diego blood group is of capital importance in anthropological research, for the aid it gives in studying the origin, composition and mixture of populations.

We thank Dr. Miguel Layrisse for the supply of the anti-Diego serum.

Mechanism of Contraction of Smooth Muscle by Drugs

It is generally believed that the process which initiates contraction in striated muscle is the depolarization of the excitable membrane of the muscle fibre, although the mechanism by which membrane excitation is linked with the contractile process is unknown[1]. When smooth muscle is caused to contract by acetylcholine there is a decrease in membrane potential[2], and it would seem reasonable to assume that the sequence of events following action of the drug on the excitable membrane is similar to that postulated for striated muscle, namely, depolarization leading to activation of the contractile element. The following experiments in which the effects of drugs were tested on smooth muscle which had been depolarized by the external administration of potassium ions suggest, however, that activation of the contractile element can be initiated by acetylcholine and other drugs without intervening depolarization.

Isolated preparations of smooth muscle, including the nerve-free amnion of the chick, rat uterus, and separated longitudinal muscle coat of the cat's small intestine, were immersed in Ringer's solution, and their contractions in response to drugs and electrical and mechanical stimulation recorded isotonically. When the sodium chloride of the Ringer's solution is replaced by 'isotonic' potassium chloride (12·3 gm./l.) or potassium sulphate (22 gm./l.) the preparation at first shortens maximally, but soon begins to relax. The degree of relaxation varies in different preparations, but its speed and extent can be increased by lowering the temperature or addition of adrenaline or isoprenaline. These preparations continue to respond to acetylcholine, histamine, 5-hydroxytryptamine and oxytocin when suspended in potassium Ringer. The effect of acetylcholine in potassium Ringer is antagonized by atropine. The response to electrical stimulation is greatly diminished (much larger stimuli required) in potassium chloride Ringer, and practically abolished in potassium sulphate Ringer. The amnion of the chick which in sodium chloride Ringer responded to a locally applied pinch with a conducted contraction of the whole preparation failed to give this response in potassium chloride Ringer.

Thus it appears that a conducted response of smooth muscle is abolished when the muscle is depolarized as it is abolished in nerve and striated muscle, but contraction in response to drugs, which is presumably due to local excitation of each smooth muscle cell, is preserved. Direct evidence of complete depolarization of the smooth muscle in potassium sulphate Ringer was obtained by intracellular recording, as will be reported elsewhere[3]. A possible explanation of these results is that drugs act directly on the contractile element, but this seems on the whole unlikely, especially with a quaternary ammonium compound such as acetylcholine or a large polypeptide such as oxytocin, which presumably does not diffuse readily into the cell interior. Another possibility is that the action of drugs on the membrane results in the liberation of a chemical agent in the interior of the fibre which activates the contractile element, but there is at present no experimental evidence to support this hypothesis.

Mechanism of Nerve-Impulse Transmission at a Crayfish Synapse

MICROELECTRODES have been inserted into both pre- and post-junctional elements of certain one-way synapses in the abdominal nerve-cord of the crayfish (*Astacus fluviatilis*). The pre-synaptic fibres are giant axons (lateral and medial) which run through the length of the cord. The post-fibre is, in each case, the largest of the motor axons which leave the ganglion in the third root. Fig. 1 shows an example of nerve-impulse transmission across such a synapse. The pre-junctional axon was stimulated with external electrodes; and its action potential, recorded intracellularly close to the synapse, is shown on the upper trace. The ensuing post-synaptic response, also recorded intracellularly from the junctional region, is shown on the lower beam. The magnitudes of the pre- and post-spikes were 92 and 70 mV., respectively. The post-spike was initiated when the synaptic potential exceeded about 20 mV. In most experiments the preparations were not in as good condition and only a synaptic potential was recorded from the post-fibre. It is difficult to assign a value to the delay between pre-spike and synaptic response. Both potentials seem to arise at about the same time but at different rates. When a test for antidromic transmission is made, it is found that a spike in the post-fibre usually gives rise to no detectable potential change in the pre-axon.

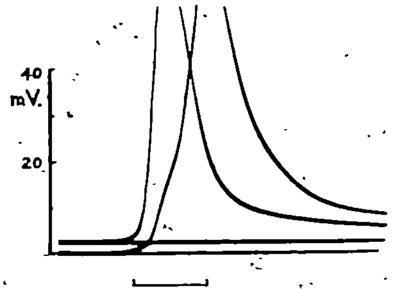

Fig. 1. Transmission of a nerve impulse across the synapse. The pre-fibre had been stimulated by means of external electrodes and the action potentials of pre- and post-fibres recorded each with an intracellular electrode. The pre-synaptic spike is shown on the upper trace, that of the post-fibre on the lower. The magnitudes of pre- and post-spikes were 92 and 70 mV., respectively. The voltage scale is for the post-fibre only. Time calibration, 1 msec.

Concerning the mechanism of the orthodromic transmission, it has been found that even subthreshold electric currents, passed through one of the internal electrodes, can produce appreciable changes in membrane potential, recorded with another electrode, on the opposite side of the synapse. This is quite different from the result which has been obtained at the neuromuscular junction[1]; and it seems very likely that different mechanisms are operating in the two cases. Whereas there is convincing evidence that transmission at the end-plate is 'chemically' mediated[2], there is good reason for believing that at this crayfish synapse the electrotonic currents accompanying the pre-spike cross the junction in sufficient strength to account entirely for the observed synaptic potentials. In addition, the junctional membrane shows marked rectifier properties which would explain the unidirectional nature of the transmission process.

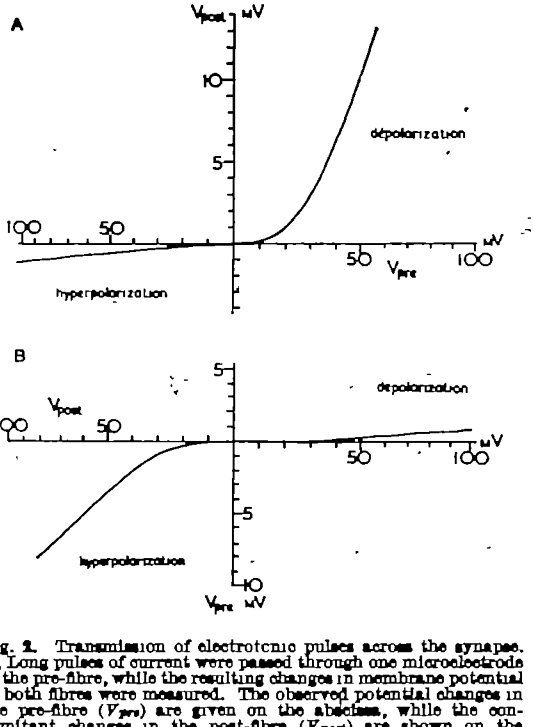

Fig. 2. Transmission of electrotonic pulses across the synapse. *A*, Long pulses of current were passed through one microelectrode in the pre-fibre, while the resulting changes in membrane potential of both fibres were measured. The observed potential changes in the pre-fibre (V_{pre}) are given on the abscissa, while the concomitant changes in the post-fibre (V_{post}) are shown on the ordinate. *B*, Similar results, but in this case the current had been passed through one of the post-fibre electrodes, and V_{post} is now shown on the abscissa.

The best evidence for these conclusions comes from experiments with four microelectrodes, in which both a voltage-recording and a current-passing electrode were inserted into each synaptic element. Fig. 2 gives some of the results from such an experiment. The observations shown in *A* were obtained by passing long pulses of current of various known strengths across the pre-fibre membrane, while the concomitant changes in membrane potential of both pre- and post-fibres were measured simultaneously. The magnitudes of the observed potential changes, which had the appearance of electrotonic potentials, are shown on the abscissa and ordinate, respectively. The currents used are not given. It can be seen that depolarizations of the pre-fibre give rise to considerable depolarizations of the post-fibre, while hyperpolarizations have little transjunctional effect. This apparent rectification by the synapse might, of course, be explained by a chemical transmission mechanism, but such an interpretation is made very unlikely by the observations made in the next part of the experiment. In *B*, the resulting potential changes are shown for the opposite situation, in which pulses were passed through the post-fibre current electrode. In this case it is the hyperpolarizations which are transmitted across the junction (antidromically), while depolarizations cross in negligible amounts. The phenomena seen in the two parts of the experiment would be simply explained if the synaptic membrane were a rectifier which passed appreciable positive current only in the orthodromic direction. Depolarizations of the pre-fibre and hyperpolarizations of the post-fibre both give rise to a potential difference across the junctional membrane of the same sign, and would cause current to flow across that membrane in the forward direction. This hypothesis was tested quantitatively by estimating the trans-synaptic currents which would account for the potential changes observed on the other side of the junction (the ordinate values of Fig. 2). It was found, as shown in Fig. 3, that this current (I_{syn}) was the same during a pre-fibre depolarization or a post-fibre hyperpolarization provided only that both gave rise to the same potential difference (V_{syn}) across the junction. Furthermore, the values of I_{syn} seem quite adequate to account for normal transmission of the nerve impulse.

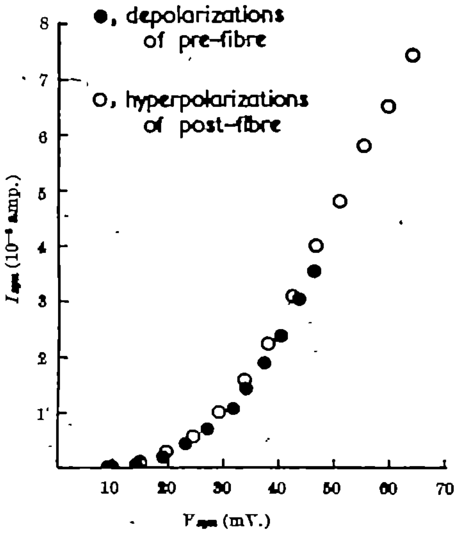

Fig. 3 Relationship between steady-state potential difference across the synaptic membrane (V_{syn}) and the apparent current traversing it (I_{syn}). The changes in V_{syn} were brought about either by passing depolarizing currents through a pre-fibre electrode (filled-in circles) or hyperpolarizing currents through a post-fibre electrode (hollow circles). $V_{syn} = V_{pre} - V_{post}$, depolarizations of pre- or post-fibre being taken as having a positive sign. I_{syn} is the magnitude of the current crossing the synapse which would account for the observed potential changes on the other side of the junction. (The latter potential changes are those given on the ordinates of Fig. 2.) When V_{syn} was negative (that is, with hyperpolarizations of pre-fibre or depolarizations of post-fibre) I_{syn} was very small; but because of the errors involved in estimating these small currents the actual values are not given

There is, then, good evidence that a one-way transmission process can take place by means of an 'electrical' mechanism, namely, one in which the local currents can cross the synaptic membrane in only one direction. This conclusion, however, probably does not apply to some other junctions in the crayfish cord; for there are indications that even this same post-fibre has other synapses on it which rely on a chemical mediator.

A Second Oxytocin in the Hypothalamus

RECENTLY[1], we compared oxytocin blood-levels in women during non-pregnancy, pregnancy, labour and lactation under similar conditions of blood collection, extraction and assay, using the sensitized virgin rat uterus. Similar experiments were performed on lactating cows and goats (Hawker, R. W., and Roberts, V. S., unpublished work) and on women who failed to lactate after parturition (Hawker, R. W., unpublished work). The test applied to the extract activity to identify it with oxytocin was its destruction by 0·01 *M* thioglycollate[2]. However, substantial activity frequently remained after thioglycollate treatment; and so it was concluded that another oxytocic substance was often present in blood. Some initial experiments regarding the origin of this have been made.

Extracts of twenty pituitaries, some of the whole gland and some of the posterior lobe only, of cows, oxen, cats (and kittens), rats and mice, were examined after thioglycollate treatment, but none was found to contain significant residual activity. Instead of the longer acid-alcohol method[1] necessary for the extraction of blood a simpler procedure was adopted. Here the tissue after removal was placed in 0·25 per cent acetic acid, immediately boiled for 3 min., ground, left to stand for approximately 30 min., and centrifuged. The supernatant was dialysed and neutralized. Extracts of the hypothalami of cows, oxen, cats (and kittens), rats and mice were next studied and, consistently, residual activities after thioglycollate were obtained. These residual activities ranged from 11 to 75 per cent of the total oxytocic activity of the extracts before thioglycollate with a mean of 35·5 per cent and a standard deviation of 18. Extracts of other parts of the brain and cord similarly treated failed to show residual activity.

This activity was not due to potassium, which had been reduced to negligible amounts by dialysis as verified by flame photometry, nor to acetylcholine or to hydroxytryptamine as the assay uterus was treated with atropine and dibenamine. Hypothalamic extracts did not prevent the inactivation of added 'Pitocin' (Parke Davis) by thioglycollate. Some properties of the residual activity of hypothalamic extracts after thioglycollate are: (1) it is retained during dialysis by a 'Cellophane' membrane; (2) its dose response curve on the virgin rat uterus is not significantly dissimilar to that of 'Pitocin' (Parke Davis) or to that of the residual activity in blood extracts; (3) it is stable on boiling for short periods; (4) it loses potency if stored at 5° C. for several days (as does 'Pitocin' in dilute solution); (5) it is not recoverable in significant amounts if the hypothalamus is left in the animal for 30 min. after death.

Thus it appears that, in addition to oxytocin, there is in hypothalamic extracts and in some blood extracts a substance which stimulates the sensitized virgin rat uterus treated with atropine and dibenamine, which is non-dialysable and the activity of which is not destroyed by treatment with thioglycollate. We are examining the properties of these substances on other means, for example, milk ejection, guinea pig ileum, to determine whether or not they are identical, and also we are endeavouring to observe whether or not a change in hypothalamic content of this second oxytocin can be correlated with changes in blood-levels of it.

Alloxan Diabetes in the Piglet

Lukens[1] depancreatized young pigs, and found that the diabetic state which followed was characterized by a slight or absent fasting glucose-excretion, and a low fasting nitrogen-excretion. Ketonuria was marked, but was not accompanied by severe acidosis. These observations are in contrast with those on the depancreatized cat or dog, and the question arises whether a pure beta-cell deficiency diabetes induced by alloxan in the pig is also different from the corresponding condition in other animals. No account of this form of experimental diabetes in the pig has been found in the literature, and this is a preliminary report on the effects of alloxan on the young pig.

The piglets used in these experiments (Landrace × Large White or Large White × Large White) were installed at about two weeks of age in funnel type metabolism cages, equipped for the measurement of food and water intakes and the 24-hourly collection of urine under toluene. The pellet diet used throughout was 'Amvilac No. 2' (Glaxo). Blood samples for glucose estimation[2] were taken from the tail, and urine glucose was estimated by Benedict's quantitative method. Room temperature was maintained at approximately 70° F. Alloxan was injected as a freshly prepared 7–10 per cent solution in 0·9 per cent sodium chloride solution, in animals weighing 5 kgm. or more; the controls received 0·9 per cent sodium chloride solution. All injections were made by the intracardiac route to ensure rapid entry of alloxan into the blood.

Table 1

	Control	Diabetic (maximum values)
Total food eaten in 8 consecutive days (kgm.)	3·55	3·75
Weight gain over same 8 days (kgm.)	2·90	1·50
Urine (ml./24 hr.)	550	7,000
Glycosuria (gm./24 hr.)	0	376
Blood-sugar, feeding (mgm./100 ml.)	80–117	605
Blood-sugar, fasting (mgm./100 ml.)	38–63	303

Fourteen piglets were injected with alloxan in doses ranging from 75 to 250 mgm./kgm. body-weight; of these, six piglets were made glycosuric, including three marked diabetics. No measurable urinary ketosis (that is, more than 1 part per 100,000) was observed at any time. The effective dose of alloxan was 200–250 mgm./kgm. body-weight by intracardiac injection after a fast of 20–24 hr.; if the animal was not fasted it showed marked resistance to the diabetogenic effect of alloxan (cf. ref. 3). The blood-sugar and urinary glucose excretion rose together; the maximum values observed are compared with control values in Table 1 (pigs weighing approximately 8 kgm.).

The alloxan diabetic pig showed a diabetic type of response to the intravenous glucose test (0·5 gm. glucose/kgm.), and the glycosuria and urinary nitrogen were approximately parallel to the food intake. Weight gain continued, although at a reduced rate; the animal was relatively insensitive to insulin.

Differential staining of pig pancreas is difficult; the best procedure found so far includes Zenker-formol fixation and staining by Gomori's chrome-hæmatoxylin phloxine[4], which allows differentiation of alpha and beta cells and acinar tissue. Pancreas from a pig treated effectively with alloxan shows an absence of beta cells while the alpha cells remain readily apparent.

Alloxan diabetes in the young piglet appears to be similar to alloxan diabetes in some other species. The dose, at 200–250 mgm./kgm., is high as compared with the dog (60–75 mgm./kgm.) or mouse (100 mgm./kgm.), but not in comparison with the monkey (300 mgm./kgm.)[5]. The diabetic piglets were followed for three weeks; during that time they did not appear ill, blood-sugar was high, there was no apparent ketosis and they were relatively insensitive to insulin. Despite the unusual features of the depancreatized pig noted earlier, the relation the alloxan diabetic pig bears to the depancreatized pig of comparable weight appears similar to the relation between alloxan diabetic and depancreatized dogs[6], in that the alloxan diabetic showed higher blood-sugars, no severe ketosis, and no dependence on insulin.

I wish to thank A. Legge for technical assistance.

Activity and Specificity of Rennin

Although proteolytic activity has been shown by Berridge[1] in a partially crystalline preparation of rennin, and by De Baun, Connors and Sullivan[2] in a preparation 75 per cent pure, there has hitherto been no published proof that the activity is not due to contamination. Moreover, it has been implied that rennin has only weak proteolytic activity[3].

Crystalline rennin has been prepared by the method of Berridge and Woodward[4] from Benger's commercial rennet. Evidence has now been obtained that it is a powerful proteolytic enzyme with a specificity similar to that of pepsin. Proteolytic activity was measured on denatured hæmoglobin by the method of Anson as described by Northrop, Kunitz and Herriott[5], and milk-clotting activity was measured by the technique of Berridge. Throughout the purification, the ratio of these two activities remained constant. This applied even to the later supernatants from salting out with sodium chloride. Recrystallization of rennin has no significant effect on its activity.

	P.A.	*R.*
1st crystallization	0·104	2·33
Mother liquor from 1st crystallization	0 076	2·37
2nd crystallization	0·108	2·42
Mother liquor from 2nd crystallization	0·118	2·44
3rd crystallization	0·113	2 27

P.A.: Proteolytic activity per mgm. of total nitrogen in units exactly as defined in ref. 5.
R: Ratio of milk-clotting activity (in units defined by Berridge) to proteolytic activity.

It can be seen that, measured in this way, rennin has a proteolytic activity similar to that of trypsin and quite comparable with that of the other endopeptidases.

The *B* chain of insulin was considered to be a good substrate for an initial study of the proteolytic specificity of rennin. In most experiments, 1·5 mgm./ml. of the *B* chain was incubated overnight at 30° C. with 0·03 mgm./ml. of twice-crystallized rennin. The digest was then freeze-dried and subjected to ionophoresis on Whatman No. 4 paper at *p*H 6·5. The peptide bands were eluted and the eluates hydrolysed with 20 per cent hydrochloric acid, using the techniques of Sanger and his colleagues[6]. The hydrochloric acid was removed and the constituent amino-acids of the separated peptides were identified by one-dimensional chromatography with phenol/ammonia and also *sec*-butanol/formic acid solvent mixtures. The results indicate that rennin splits the *B* chain of insulin in the following positions:

Phe. Val. Asp. Glu. His. Leu. CySO$_3$. Gly. Ser. His. Leu ${}_1\uparrow$ Val. Glu.

Ala. Leu. ${}_2\uparrow$ Tyr. ${}_3\uparrow$ Leu. Val. CySO$_3$. Gly. Glu. Arg. Phe. ${}_4\uparrow$ Phe. ${}_5\uparrow$

Tyr. Thr. Pro. Lys. Ala.

These are all bonds which are split by pepsin. In contrast to chymotrypsin, which also splits some of these bonds, rennin does not liberate the peptide Thr. Pro. Lys. Ala. from the *B* chain, neither does it act on the chymotrypsin substrate acetyl-tyrosine ethyl ester. However, although the *B* chain digestion by rennin has been repeated several times, no evidence has been found for the breakage of additional bonds which Sanger and his colleagues have found to be split by pepsin. This slightly narrower specificity of rennin is confirmed by comparisons between rennin digests of the *B* chain with pepsin digests. Another difference is that a rennin digestion always leaves equal quantities of the peptides Phe. Tyr. Thr. Pro. Lys. Ala. and Tyr. Thr. Pro. Lys. Ala., whereas pepsin may leave only a trace of the former peptide. Experiments on the progress of the digestion indicate that rennin splits bond 1 more slowly than bonds 2, 3, 4, and 5.

Since pepsin has been shown to be present in commercial rennet, it is important to eliminate any possibility of pepsin contamination interfering with specificity experiments. The presence of 5 per cent of pepsin can be quantitatively detected by electrophoresis. A 0·8 per cent solution of twice-crystallized rennin showed a single symmetrical peak during Tiselius electrophoresis at *p*H 6·5. 5 per cent of crystalline pepsin was added to an identical solution and another electrophoresis was performed. After half an hour a small peak with 5 per cent of the area of the main peak separated. A 4 hr. rennin digest of the *B* chain was then compared with a digest obtained under identical conditions but using a pepsin solution 5 per cent the strength of the rennin solution. Splitting of the *B* chain was considerable in the rennin digest but was negligible in the pepsin digest.

The fact that the action on the *B* chain is not due to pepsin has been further shown by quantitative experiments on the *B* chain using the ninhydrin method of Moore and Stein for following the digestion. Pepsin has an optimum for effect on the *B* chain of about *p*H 2, whereas that of rennin is *p*H 4.

It has been shown chromatographically that rennin at *p*H 6 splits the pepsin substrate carbobenzoxy-glutamyltyrosine. As with pepsin, long incubation periods and high concentrations of enzyme are required.

In conclusion, it must be noted that Holter and Li[7] found that crystalline rennin prepared by Berridge[1] had phosphoamidase activity on the substrate N-(*p*-chlorophenyl)-amidophosphoric acid. Attempts to confirm this on a substrate supplied by Light and Co., Ltd. ('*p*-chloranilidophosphonic acid (Phosphoamidase)'), have failed. Although activity was present in the commercial rennet (measured by the liberation of phosphate as described by Holter and Li), no activity could be detected in crystalline rennin. The substrate gave a high blank. It is suggested that the phosphoamidase activity is due to a contaminant which is not present in crystals prepared by Berridge's latest method.

I am grateful to Dr. F. Sanger for samples of the *B* chain of insulin, to Mr. M. Norton for kindly demonstrating techniques, to Mr. B. Slater for performing the Tiselius electrophoresis, and to Dr. E. C. Webb for advice and encouragement. Full details of this and other work on rennin will be published elsewhere.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Guide Lecturer at the Geological Museum, London, S.W.7—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting Ref. No. S4739/57 (August 23).

Chemist (with an honours degree, A.R.I.C., or equivalent) **in the Research Laboratories**, Leatherhead, Surrey, for work on insulating and lubricating oils and the study of oxidation and anti-oxidation—The Director of Establishments, Central Electricity Authority, Winsley Street, London, W.1, quoting Ref. N./346 (August 24).

Research Assistant (with research experience (academic or industrial) in polymer science) **in the Department of Chemistry**, to assist in a programme of work on the synthesis of polyethers and a study of their physical properties—The Registrar, The University, Manchester 13 (August 26).

Assistant (with a good degree in anthropology or sociology, and preferably postgraduate experience of field research) **in the Department of Social Anthropology**—The Secretary, The University, Edinburgh (August 31).

Experimental Officer (with a degree in physics, national certificate in applied physics or equivalent) **in the Physics Department**, to assist on the instrumental side of agricultural meteorology, particularly on the water and energy requirements of growing plants—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (August 31).

Lecturer in Agricultural Chemistry—The Bursar, Shuttleworth College, Old Warden Park, Biggleswade, Beds (August 31).

Senior Lecturer or Lecturer (graduate in either science or medicine) **in the Department of Surgical Science**—The Secretary, The University, Edinburgh (September 1).

Junior Assistant Physicist (preferably with previous hospital experience), for duties concerned with routine radiotherapy physics, and the clinical use of radioactive isotopes—The House Governor, Charing Cross Hospital, London, W.C.2 (September 2).

Post-doctoral Research Fellow in Carbohydrate Chemistry—The Secretary, Birkbeck College, Malet Street, London, W.C.1 (September 6).

Scientific Officer (male, with an honours degree in science) **in the Plant Diseases Division**, New Zealand Department of Scientific and Industrial Research, Lincoln, for investigations and identification of diseases of field crops, and testing plant varieties for disease resistance—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting Ref. No. 3/64/187 and mentioning *Nature* (September 6).

Lecturer (graduate, with recognized professional qualifications) **in the Department of Engineering**, University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 9).

Second Chair in Agriculture at King's College, Newcastle-upon-Tyne—The Registrar, University Office, 46 North Bailey, Durham (September 14).

Lecturer in Physics at Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, September 20).

Research Fellow in the Department of Botany, University College, Ibadan, Nigeria, for research into the physiology of host-parasite relationships of *Striga*—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 23).

Staff Tutor (with good qualifications in any branch of the physical sciences) **in Physical Science**—The Director of Extra-Mural Studies, The University, Edmund Street, Birmingham 3 (September 30).

Lecturers (2); and a **Graduate Assistant in the Computing Unit**—The Secretary of Faculties, University Registry, Oxford (October 1).

Assistant, Grade B (with a good honours degree), **for Mathematics**—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham.

Assistant (graduate, with library qualifications and experience) **in the Library**—The Registrar, The University, Nottingham.

Assistant Lecturer in the Chemical Physics of Solids—Prof. A. R. Ubbelohde, Department of Chemical Engineering, Imperial College, London, S.W.7.

Assistant or Associate Professor (preferably plant biochemist with Ph.D.) **in Agricultural Biochemistry** at Ontario Agricultural College—Dr. D. Waghorne, c/o Miss M. A. Ball, 25 Kimberley Road, Cardiff, until September 14, or afterwards to the Department of Chemistry, Ontario Agricultural College, Guelph, Canada.

Chemist (young graduate) to assist in a variety of organic preparations connected with researches on biological activity—Dr. O. J. W. Brooks, Clinical Chemotherapeutic Research Unit, Medical Research Council, Western Infirmary, Glasgow, W.1.

Chief Technician to supervise Technical Staff in the Department of Chemistry—The Assistant Secretary, Birkbeck College, Malet Street, London, W.C.1.

Demonstrator (with an honours degree in botany, and at least one year's postgraduate experience in mycology, plant pathology or microbiology) **in Horticultural Science**, to assist in the laboratory and other practical work in mycology and allied subjects for the (postgraduate) diploma courses in plant pathology and protection and in horticultural science—The Registrar, The University, Bristol.

Entomologist, Assistant Colonial Liaison Officer (with a good honours degree in zoology or entomology, and preferably postgraduate experience, and willing to undertake occasional tours abroad of some months duration)—The Director, Pest Infestation Laboratory, D.S.I.R., London Road, Slough, Bucks.

Hospital Biochemist with an honours degree, preferably in biochemistry or chemistry), to participate in research into biochemical aspects of fungal diseases of the skin—The Group Secretary, Huddersfield Hospital Management Committee, The Royal Infirmary, Huddersfield.

Junior Lecturer (with an honours degree in chemistry, and preferably previous teaching experience) **in the Department of Chemistry**—The School Secretary, Middlesex Hospital Medical School, London, W.1.

Laboratory Steward to take charge of Botany and Zoology Laboratories at Brighton Technical College—The Director of Education, County Borough of Brighton Education Committee, 54 Old Steine, Brighton.

Physicist (with a degree or equivalent, and experience in crystallography, vacuum technique, X- or gamma-radiography or photography) **in the Research Laboratories**, Leatherhead, Surrey, to work on X-ray diffraction—The Director of Establishments, Central Electricity Authority, Winsley Street, London, W.1, quoting Ref. N/347.

Research Assistants (2) (chemistry graduates) **in the Department of Chemistry**, to engage upon original work in one of the following fields of study: (*a*) inorganic chemistry, (*b*) organic chemistry, or (*c*) physical-organic chemistry, with a view to preparing for the Ph.D. degree (London, Internal)—Head of the Department of Chemistry, Chelsea Polytechnic, London, S.W.3.

Research Fellow, for work on natural products—The Secretary, The University, Southampton.

PERMUTIT
ION EXCHANGE *in the*
CHEMICAL INDUSTRY

Yet another application of Permutit Ion Exchange is the deacidification of formaldehyde, which is performed by the Permutit plant illustrated here. Increasing numbers of Permutit Ion Exchange plants are now being used to improve and accelerate many chemical and metallurgical operations. Perhaps in *your* industry Permutit can help to improve the product or reduce costs. For full technical information and advice, please write to :—

THE MICROID
Flask Shaker
Registered Design No. 84286

- SILENT
- PORTABLE
- VARIABLE SPEED
- WRIST ACTION

The Microid Flask Shaker is an ideal labour-saving device for the modern laboratory. In the daily routine operations of dissolving and dispersing solids, extracting residues and emulsifying oils, it not only abolishes the tedious process of prolonged shaking by hand, but also speeds up reactions. This shaking machine accommodates up to four 500 ml. flasks, each half-full of liquid, and can be controlled to give agitations varying in speed up to 500 oscillations per minute. S36–670

LECTURES AND COURSES

THE POLYTECHNIC
309 REGENT STREET, W.1
DEPARTMENT OF MATHEMATICS AND PHYSICS

A course of lectures on "Electronics" will be held on Thursday evenings from 6 p.m. to 7.30 p.m., commencing September 26, 1957 The course is suitable for those who wish to take this subject in the Graduateship examination of the Institute of Physics Fee for the course: £2.

A Practical course on "Electronics" will be held on Wednesday evenings from 6 p.m. to 9 p.m., commencing October 2, 1957

A detailed syllabus of the lectures is available Application to attend the course should be made as soon as possible to the Director of Education

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY
CHEMICAL ENGINEERING DEPARTMENT

Applications are invited from graduates for a one-year full-time course in Ceramic Technology, leading to the Diploma of the Imperial College, which will begin in October, 1957.

Further particulars from the Deputy Registrar, City and Guilds College, Exhibition Road, London, S W 7

UNIVERSITY OF MANCHESTER

The next session commences on Thursday, October 3, 1957.

OFFICIAL APPOINTMENTS

HUDDERSFIELD HOSPITAL MANAGEMENT COMMITTEE

Applications are invited from holders of an honours degree, preferably in biochemistry or chemistry, for the full-time post of Hospital Biochemist to participate in research into biochemical aspects of fungal diseases of the skin. Duties will be undertaken at the Royal Infirmary, Huddersfield, and the Department of Biochemistry, University of Leeds, and opportunities will be afforded to work for higher degree Salary will be in accordance with Whitley Council scales.

Applications stating age, qualifications, and experience, and accompanied by copies of two recent testimonials, should be addressed to the undersigned as soon as possible.

H J JOHNSON,
Group Secretary.

Huddersfield Hospital Management
Committee,
The Royal Infirmary,
Huddersfield

CHARING CROSS HOSPITAL
LONDON, W C.2

Applications are invited for the post of Junior Assistant Physicist The duties will be concerned with routine radiotherapy physics, and the clinical use of radioactive isotopes There will be opportunities for research in the clinical application of radio-isotopes. New laboratories are being prepared for isotope work Previous hospital experience is desirable but not essential. Salary according to Whitley scale. There is a probationary period of two years for new entrants, at a salary of £575 by £25 to £625 with or £475 by £25 to £575 without honours degree

Applications, quoting two professional referees, should be sent to the House Governor, by September 2, 1957.

UNIVERSITY COLLEGE OF SWANSEA

Applications are invited for a Senior Research Studentship in either Engineering or Chemical Engineering or Metallurgy which is tenable for one year from October 1, 1957, and may be renewed for a second year. The value of the Studentship is between £500 and £700 per annum.

Further particulars may be obtained from the Registrar, University College, Singleton Park, Swansea, by whom applications must be received by Wednesday, August 28, 1957.

MINISTRY OF AGRICULTURE, FISHERIES and Food require two Assistant Experimental Officers to be stationed at Hull and Nottingham, for research on insect control. Minimum qualifications: G C.E. in five subjects with advanced level in botany, zoology, and chemistry. Degree in a biological subject desirable. Inclusive salary (men) £357 10s. (at age 18) to £780 per annum (slightly less for women).—Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W 1, quoting G 262/7A. Closing date September 7, 1957

NEW SOUTH WALES UNIVERSITY OF TECHNOLOGY
SYDNEY, AUSTRALIA
VACANCY FOR ASSOCIATE PROFESSOR OF PHYSICS
SCHOOL OF APPLIED PHYSICS

The University invites applications for appointment to the position of Associate Professor in Physics which will become vacant on January 1, 1958. Salary £A 2,415 per annum Applicants must possess a higher degree in physics and submit evidence of extensive original work Research record (academic or industrial) and teaching experience will be considered as important. The Associate Professor will be required to act as deputy to the Head of the School, and to supervise the teaching work of the School. He will be expected to lecture in selected branches of physics to advanced undergraduate classes, and will have opportunity to develop postgraduate classes and to carry out and to direct research Experimental facilities exist for X-ray, optical, vacuum and magnetic studies and the School is adjacent to the University's high-speed digital computer. Further particulars may be obtained from the Head of the School of Applied Physics, Kensington, New South Wales Successful applicant will be eligible, subject to medical fitness, to contribute to the State Superannuation Fund, for a pension of £A 1,270 per annum Professors are eligible for six months' study leave on full salary after three years of service or twelve months after six years of service The University reserves the right to fill the position by invitation First class shipping fare to Sydney of successful applicant and his family will be paid.

Five copies of applications (including the names of two referees), should be lodged with the Agent General for New South Wales, 56-57 Strand, London, W.C 2, and a copy forwarded in an envelope marked "University Appointment," by airmail to the Bursar, Box 1, Post Office, Kensington, New South Wales, Australia, by October 1, 1957.

NOTTINGHAM AND DISTRICT TECHNICAL COLLEGE
SHAKESPEARE STREET, NOTTINGHAM

Applications are invited for the following posts: Assistant, Grade B in Physics; Assistant, Grade B, in Chemistry Salary in accordance with Burnham Technical Scale as follows: £650 by £25 to £1,025 per annum. Additions include degree allowance of £75 per annum (or £125 for good honours degree), up to three increments of £25 for training in approved cases and incremental allowance for industrial experience after age 21 and war service.

Further particulars and form of application may be obtained from the Principal Completed forms should be returned not later than August 31, 1957

METALLURGIST REQUIRED BY THE Atomic Weapons Research Establishment, Aldermaston, Berks, to take charge of a Development and Process Laboratory and Heat Treatment Section attached to an Engineering Group responsible for: (1) Chemical and mechanical testing for the approval of incoming metals (2) Versatile heat treatment department working in conjunction with an experimental engineering workshop (3) Advice to Design Engineers on the selection of materials, processes and methods of fabrication and organizing subsequent processing Investigation of service failures and initiation of development work on a variety of metallurgical and machining problems form a very important part of the duties involved. A.I.M and extensive industrial experience in ferrous and non-ferrous metallurgy and in non-destructive testing required Applicants should also have held a responsible post involving the control of industrial labour. Salary: £1,235 to £1,655 per annum (male) Contributory superannuation scheme. A house or assistance towards legal expenses on house purchase will be available for married officers living beyond daily travelling distance—Postcards for application forms to the Senior Recruitment Officer at above address. Please quote ref. 1554/34

BERMONDSEY AND SOUTHWARK HOSpital Management Committee Group Laboratory at St. Olave's Hospital, Lower Road, S E 16, requires a Medical Laboratory Technician Candidates must hold appropriate qualification of the Institute of Medical Laboratory Technology, or a recognized qualification Good study facilities for further advancement Salary in accordance with Whitley Council agreement £515 rising to £630 per annum plus London weighting —Application, together with names of three referees, to the Secretary at above address

GOVERNMENT OF TANGANYIKA
COMPUTER (HYDROGRAPHICAL AND TOPOGRAPHICAL SURVEYS),
LANDS AND SURVEYS DEPARTMENT

Qualifications

Either (i) A degree (preferably with Honours) in Engineering or Mathematics or Physical Science or Geography and the Intermediate Examination of the R.I.C S (Land Surveying Section)

or (ii) The full Professional Associateship of the R I.C.S. (Land Surveying Section),

or (iii) A Licence to practice as a Surveyor in Canada, Australia, New Zealand or South Africa;

or (iv) Honours degree in Mathematics or Physics.

Age limits. Below 40 years Women candidates would be considered.

Duties Computation of Surveys of a Geodetic Astronomical or cadastral nature and the keeping of records

Terms of Appointment. On contract/gratuity terms for one tour of 30 to 36 months with emoluments in the scale £1,107 to £1,863 per annum. Gratuity of 13½ per cent of emoluments on satisfactory completion of contract Outfit allowance Free passages. Quarters provided if available at rental. Free medical attention Generous leave. Taxation at low local rates

Apply to Director of Recruitment, Colonial Office, London, S W 1. State age, qualifications and experience Quote: BCD 107/8/06

WYE COLLEGE
(UNIVERSITY OF LONDON)

The Governing Body of Wye College invites applications from graduates in science who have specialized in biochemistry for the May and Baker Research Fellowship The candidate selected will undertake research work on plant growth regulating substances under the direction of the Head of the Department of Physical Sciences, Professor R L. Wain The Fellowship is of the value of £700 per annum, renewable annually up to a maximum of three years.

Applications, accompanied by copies of two testimonials, and the names of two referees, should reach the Registrar, from whom further particulars can be obtained, not later than September 21, 1957

EXPERIMENTAL OFFICERS AND ASSISTant Experimental Officers in various Government Departments. The Civil Service Commissioners invite applications for pensionable posts The posts are divided between following main groups and subjects (a) Mathematical and Physical Sciences, (b) Chemistry and Metallurgy, (c) Biological Sciences, (d) Engineering subjects, and (e) Miscellaneous (including, e g., Geology Library and Technical Information Services) Age limits: For Experimental Officers, at least 26 and under 31 on December 31, 1957; for Assistant Experimental Officers at least 18 and under 28 on December 31, 1957 Extension for regular service in H.M. Forces Candidates aged 31 or over with specialized experience for Experimental Officer posts may be admitted. Candidates must have at least one of a number of specified qualifications Examples are higher school certificate, general certificate of education, Scottish leaving certificate, Scottish universities preliminary examination, Northern Ireland senior certificate (all in appropriate subjects and at appropriate levels), higher national certificate, university degree. Candidates taking their examinations in 1957 may be admitted provisionally. Candidates without such qualifications may be admitted exceptionally on evidence of suitable experience. In general a higher standard of qualification will be looked for in the older candidates than in the younger ones Salary (London) Experimental Officer Minimum £925 (women £853) Men's scale maximum £1,135 Assistant Experimental Officer. Starting pay £365 (at 18) up to £655 (women £632) at 26 Men's scale maximum £805 These salary scales are being increased by approximately 5 per cent. Women's scales are being raised to reach equality with men's by 1961 Somewhat lower outside London Promotion prospects Opportunities for further education —Further particulars, from Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W 1, quoting No S 94-95/57. Interview Boards arranged at intervals, as required Early application is advised.

JUNIOR TECHNICIAN/TECHNICIAN REquired in the Clinical Pathological Laboratory of this postgraduate teaching hospital An interest in biochemistry is desirable. Staff restaurant Whitley Council scale —Apply, in writing, to The Secretary, The National Hospitals for Nervous Diseases, Queen Square, London, W C 1.

GRIFFIN'S STATISTICAL MONOGRAPHS & COURSES

Edited by **M. G. KENDALL, Sc.D.**
Professor of Statistics in the University of London

This Series has been planned to meet the need for a form of publication, at moderate cost, which makes accessible to a group of readers specialized studies in statistics or special courses on particular statistical topics. Appearing in a standard cover, the text printing method used for each volume will suit the complexity or otherwise of the subject.

No. 1. *Just published*

MULTIPLE TIME-SERIES ANALYSIS M. H. QUENOUILLE, M.A.

CONTENTS: Preface — Introduction — Specification — Identification — Preliminary Investigation — Practical complications — Estimation — Significance and Goodness-of-Fit Tests — Practical Examples: U.S. Hog Series — List of Symbols — References.

108 pages. 8½″ × 5½″. 24s. net, Postage 6d.

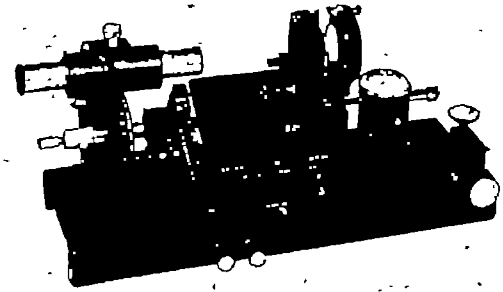
PRECISION BS INSTRUMENTS

Fabry-Perot Interferometer



Although of very simple design, this instrument is suitable for much of the work usually carried out by more elaborate and costly apparatus, and reads directly to 1/250 mm. It can be supplied with an attachment to convert to a Michelson Interferometer, thus giving a dual purpose instrument.

Price Complete	**£190 0s.**
Attachment for converting instrument into Michelson Interferometer, extra	£45 0s.
Polished wooden case, extra	£9 10s.

PROGRESS AND RESPONSIBILITY IN INDUSTRY

MR. JULIAN M. LEONARD'S presidential address at Leeds to the Society of Chemical Industry delivered on July 9, and Dr. W. J. Worboys's address as the Society's medallist on the following day, were curiously complementary. They were also in the same pattern as Sir Alexander Fleck's Messel Memorial Lecture to the Society last October, and some of the points made by Mr. Leonard and Dr. Worboys bear closely on the current discussions on technical change which have been stimulated by the recent report by Prof. C. F. Carter and B. R. Williams on "Industry and Technical Progress". Sir Alexander, it may be recalled, was prompted both by the life and work of Messel and by the celebration by the Society of its seventy-fifth anniversary to look back over that period in chemical industry and to ask some pertinent questions about the rate of progress—whether it could be maintained, whether research in the industry was wisely directed and, especially, whether the rate of development was sufficiently in line with both economic and social requirements.

Sir Alexander's emphasis on the social aspect and his reference to Sir Philip Morris's remark that industry cannot afford to operate in a cultural desert was reflected more especially in Dr. Worboys's address. Mr. Leonard's review of the era of change—the term by which he designated the past eighty years of chemical industry—was concerned more especially with the economic and legal factors which now circumscribe the initiative and enterprise of existing manufacturers and still more of those who seek to undertake new manufactures. Sketching the different conditions which to-day confront the pioneer, he did indeed indicate that those conditions are the expression of a larger sense of social or public responsibility; but the picture he presented was one that gave sufficient evidence of obstacles which the community has itself created to enterprise and development. In the aggregate, the Factory Acts the Explosives Acts, the Petroleum Acts, the Alkali, etc., Works Regulation Act, the Electricity Regulations, the Distribution of Industries Act, the River (Prevention of Pollution) Act, the Clean Air Act, to name only some that Mr. Leonard mentioned, however wise and essential they may be, do in fact constitute a check to enterprise, and it is well to be reminded that for such safeguards the community itself has to pay a price.

Mr. Leonard did not discuss monetary policy or marketing in any detail, and in his reference to labour policy and industrial relations he clearly agreed with what Sir Alexander Fleck had said in his Messel Memorial Lecture. However, he frankly expressed his anxiety whether, in the face of the conditions he described and especially those which we ourselves as a State have created, existing small chemical businesses—which still comprise the bulk of the industry—can continue to prosper, and new entrants to the industry can succeed, in their ventures; and he remarked that this position represents a challenge. Sir Alexander Fleck has emphasized the contribution which chemistry and chemical industry are making to our national wealth, and Mr. Leonard observed that the industry must of necessity take an increasingly important place in an expanding world economy and that the backward countries and underdeveloped areas might in the future offer new opportunities and fields of expansion. The difficulties to which he directed attention arise only to be surmounted by those with resolution, courage and vision, and especially the ability to adapt themselves to changing conditions.

Dr. Worboys referred even more explicitly than Mr. Leonard to the impact of chemistry on daily life, as well as on transport and communications; but, in the picture of our world which he drew in this address, he was concerned to point to changes in the political as well as in the economic position of Britain—which are sources of both strength and weakness—and to their implications. Although British exports of manufactured goods in 1955 were approximately ten times the value of exports in 1900, Britain now accounts for only 10 per cent of the Western world's production of manufactured goods, compared with 20 per cent in 1900. Moreover, he believes it would be wrong and dangerous to assume that in the future the United Kingdom must be mainly an exporter of capital goods and that consumer goods have only a small part to play in the country's exports. To be sure of sharing in this trade, British products must be of good design and good quality, and sold and serviced with vigour and real knowledge of the requirements of the overseas markets and the competition to be met.

In producing such products—and especially novel products—established technologies and wide industrial experience are great assets, but Dr. Worboys pointed out that the expanding home market in Britain resulting from the doubling of the national income per head of the population during the past fifty years is a source of weakness as well as of strength. While a healthy home market provides a good base for exports, competing demands at home could reduce the tonnage available for export unless the manufacturer is prepared to take risks and invest in additional plant. Here the factors stressed by Mr. Leonard operate, and the increased imports necessitated by increasing production could also be a source of weakness, as could the political changes to which Dr. Worboys next referred, in the absence of a growing sense of responsibility.

Universal suffrage and not nuclear energy, suggested Dr. Worboys, is the greatest uncontrolled force in our lives, politics being the pursuit of power; and power, in a democracy, being decided by elections. That is an over-simplification and ignores the factor of influence, but Dr. Worboys did well to remind us that a political system based on universal suffrage has weaknesses as well as substantial and precious advantages. The challenge of reducing those weaknesses to a minimum has been more commonly evaded than faced, and Dr. Worboys's suggestion that the best, if not only, hope lies in a growing sense of responsibility throughout the spectrum of adult population and less group and individual selfishness has been promptly underlined by subsequent events.

What perhaps seems even less certain than when he spoke is that education is the only method, and whether group selfishness in particular will allow the time required for that slow process. None who occupy positions of authority or influence can ignore, however, his responsibility for seeing that the attempt is made, or for challenging policies that are based on fallacies. Unless the responsibilities of industrial leadership are fairly accepted and faithfully discharged, a common level of poverty rather than higher living standards for the mass of the people is likely to result.

The clear thinking which Dr. Worboys urged need not involve party politics; but it does involve the acceptance of political responsibilities as citizens and responsibility for leadership in industry. Dr. Worboys was concerned primarily with the health of British industry in general, but his prerequisites are no less valid for the nationalized industries and public services than for the chemical industry. Political climate apart, his four conditions—good research, good technological development, good commercial exploitation and good personnel policy—are valid generally, and deficiencies in all four sectors have probably contributed in greater or less degree to the unhappy situation in road transport, for example. All can contribute to the effective team-work which is the condition of success in the public services as in manufacturing industries. When all concerned recognize the objective and are in sympathy with it, the disputes and bitterness that are too common to-day will disappear.

Dr. Worboys suggested that the senior managers in industry bear a heavy responsibility for starting or accelerating the educational processes which alone can bring about real team-work in industry. It is their responsibility to recognize what are the requirements for an industry to be healthy and to see that those requirements are understood by the Government, the administration and by members of Parliament. This will require conscious effort and is not a task that can be left to the public relations or internal relations officers, although their techniques might be able to help.

Dr. Worboys did not hesitate to affirm that Britain's wealth is, in the main, the sum of the profits of all the companies operating in or from the United Kingdom, and, like Mr. Leonard, he emphasized the importance of under-developed areas as markets, urging that we should be concerning ourselves with the expansion of markets and the creation of new ones, especially through the raising of the standard of living among the people of Africa, India and Asia. Here, like Mr. Leonard, he indicated the necessity of being ready to face change, particularly in the pattern of production and exports. In connexion with the growing international competition as well as with the development of team-work in industry and the furtherance of the public understanding of the purposes and needs of industry, it falls, he suggested, within the sphere of activity of the Society of Chemical Industry to create a new group or section or to make some other arrangement for the discussion by its members of matters touching on the health of British industry. He was particularly insistent on the need for more profit-producing work to be put in before more profit is taken out either as dividends, wages or taxes.

There is *prima facie* evidence in all three of these addresses that such matters bear closely on the continuing practice of applied chemistry; but here, and in the two points he stressed in closing, Dr. Worboys touched on matters which equally involve the creation of an appropriate political climate. Men are not equal, he asserted, and the most we can do is to ensure that all children have equal opportunities to develop. By doing so, we can ensure that the best use is made of the country's prime asset—its people.

That is a further reason why educational policy is of outstanding importance, though from a wider angle than that from which it was considered in the recent conference at Leeds, which was concerned primarily with the supply of scientists and technologists for industry. Dr. Worboys's emphasis on management, however, in itself indicated the supreme importance of a supply of able minds, of character as well as of intellect; but the stress here lies on the creation of a climate of opinion which will ensure that educational opportunities are not destroyed in the service of party political doctrine or prejudice. His second point—the pressing need for the re-creation of incentives—is no less largely a matter of the climate of opinion; indeed, in so far as Dr. Worboys is right in holding that in the United Kingdom the improvement of monetary incentives is mainly a question of taxation, it could easily become a matter of party politics.

If that be so, it is the more important that this aspect of taxation policy should be the subject of impartial and authoritative inquiry, so that opportunity should be given for the creation of an independent body of opinion to enforce action demanded in the country's interest, even if it is not in line with party doctrine. It is disappointing to find that the recent conference on "Capital for Scientific Development" held at the Royal Society of Arts scarcely faced such issues, although Prof. C. F. Carter at least put some of the necessary questions (see *Nature*, August 17, p. 307). Finance may well be a less serious problem than the shortage of scientists and technologists and the quality of management, as Prof. B. R. Williams said at Leeds; but the creation of healthy conditions for industry is largely a matter of removing hindrances and establishing the confidence and understanding which promote co-operation and goodwill. We need more such realistic addresses as that by Dr. Worboys, with its fearless facing of awkward questions, more impartial inquiry and more clear thinking and honest acceptance of responsibility. For its example as well as for its stimulus to such thought and endeavour, Dr. Worboys has earned the gratitude of a much wider circle than members of the Society of Chemical Industry. It is well to be reminded of how much food supply, health, transport, communications and comfort depend on chemical industry and on industry in general; but we need still more to be reminded at this time that the prosperity of industry depends equally on the state of the nation. Unless we provide the conditions which encourage and reward responsibility, ability and constructive work, we are unlikely to find the new answers to old questions which are demanded if Britain's economic future is to be secure in this modern world.

LIFE IN THE ABYSS

The Galathea Deep Sea Expedition, 1950–1952

Described by Members of the Expedition. Edited by Dr. Anton F. Bruun, Sv. Greve, Hakon Mielche, and Dr. Ragnar Spärck. (Translated from the Danish by Reginald Spink.) Pp. 296. (London: George Allen and Unwin, Ltd., 1956.) 40*s*. net.

AN exploring voyage with a deep sea expedition must be one of the most stimulating experiences that a biologist can enjoy—no marine biologist would willingly forgo the opportunity of serving in one. Since the days of Edward Forbes and the *Challenger*, much knowledge of the depths of the oceans had been accumulated as the result of expeditions sent out by many nations, but the most long-sustained studies must surely be the researches made in the southern oceans by the ships of the *Discovery* investigations which continued for nearly a quarter of a century. Denmark has made her full contribution to the exploration of the sea, from the cruise of the corvette *Galathea* a little more than a hundred years ago to the researches of Johannes Schmidt and his culminating *Dana* world expedition. Another Danish expedition to study the greatest abyssal depths had been under discussion for some years, but it was not until 1948 that serious planning could be undertaken, planning that resulted in the sailing of the *Galathea*, formerly the sloop H.M.S. *Leith*, on her circumnavigation of the world in October 1950.

The primary purpose of the *Galathea* expedition was to explore the ocean trenches in depths exceeding 6,000 metres in order to find out if life occurred under the extreme conditions prevailing there. Large-scale dredging was to be carried out to find whether, and to what extent, there are large and active animals in the abyss and at somewhat higher levels. Quantitative methods were also to be used for studying the fauna of the shallower tropical seas as well as the great depths. Many other subsidiary lines of research were to be carried out provided they did not interfere with the main objects. In addition, visiting scientists were encouraged to join the expedition for limited periods; at ports of call an endeavour to spread a knowledge of Danish culture was to be made by means of films and lectures, and films and recordings were to be made for broadcasting over the Danish radio.

This was indeed an enormous task, and the expedition's return with so much of it successfully accomplished was largely due to the energy and wisdom of its leader, Dr. Anton F. Bruun, who makes handsome acknowledgment to his staff and colleagues. The present volume is a popular account of the work of the expedition written by its members, each of whom contributes a chapter or two on his own speciality. Technical matters are explained so that the layman can understand the conditions of life in the sea, especially at great depths, and some of the problems of oceanography and the methods of studying them. The book is ably translated from the Danish by R. Spink, and is well illustrated with drawings and photographs. The fact that it was set up and printed in Denmark no doubt accounts for a number of misprints, most of them obvious and of minor importance.

The subjects of the chapters vary widely, from echo-sounding and the technique of trawling, to sea snakes and geomagnetic investigations, but those of greatest interest to marine biologists are probably the ones dealing with the fauna of the abyssal trenches, the Philippine, Kermadec, Tonga, and other trenches. In the first of these deeps specimens were obtained from depths of more than 10,000 metres and included coelenterates, echiuroids, holothurians and bivalve molluscs. At these great depths, too, large quantities of waterlogged vegetable debris derived from the land were found—sticks, branches, leaves, palm and mangrove fruits, and much else. It is commonly believed that a rain of dead plankton animals sinks to the bottom from the surface layers. Dr. Bruun points out that dead organisms are as rare a sight in the sea as they are on land. "Sick or weak animals fall a prey to stronger enemies and are devoured. . . . The microscopic plants sink very slowly, and must be consumed in the first few hundred metres; lower down they can certainly be traced only in very scanty quantities. This, no doubt, is why the discontinuity layer between the water masses in the warm, upper thermosphere and the cold, deeper psychrosphere . . . is so rich in pelagic animals." In this layer the cold of the deep stops the animals from above, and the warmth of the upper layer stops those from below. Beneath the layer very little food is available, for it has nearly all been eaten, and for thousands of metres below it higher animal life is very sparse. But on the bottom where everything not already eaten comes to rest, especially land-derived plant remains the cellulose of which is not digestible by most pelagic animals, the fauna is much richer than in the barren tract between the discontinuity layer and the bottom. Whenever the trawl came up from the great depths with a bag-full of plant remains the zoologists knew at once that a good catch of animals would be revealed when the contents of the net were emptied. "Dead vegetable material of this kind can hardly be broken down by the gastric juices of animals; but bacteria can cope with both cellulose and with everything else, and they in turn can be consumed by mud-eaters which gorge themselves on the soft oozy bottom, such as the bristle-worms, sea-cucumbers, and bivalves. And then a new link can be added to the food chain; namely, crustaceans, which eat the worms and in turn are eaten by fishes." Dr. C. E. ZoBell, of the Scripps Institution of Oceanography, who accompanied the expedition for part of the time, was able to demonstrate the presence of large numbers of bacteria in the mud from the greatest depths, and to grow them in culture media under pressures of up to 1,000 atmospheres and at low temperatures—conditions approximating to those found in the abyss. He showed that they were truly barophilic because there was no growth in the cultures subjected to atmospheric pressure. "Although from 0·0002 to 0·02 grams of bacteria per square metre of ocean floor may be considered a small 'standing crop' as compared with the crops harvested from fertile garden soil, this amount compares favourably with the total weight of animals found by zoologists on the *Galathea* Expedition."

The main object of the expedition was to explore the greatest depths, and undoubtedly one of the most important biological results achieved was this elucidation of the ecology of the abyss, and the demonstration that the idea of a constant rain of food material from above is a misconception. The basic food material does come from above, but far from being a product of the sea derived from planktonic organisms, it is directly derived from the land in the form of the cellulose of higher plants.

This book gives an absorbing account of the progress of the expedition, and an excellent general view of the scientific results obtained. Specialists will look forward to the appearance of the detailed monographs reporting on the very large and important collections that were brought back, which will no doubt be presented in the form of a series of volumes to be published over a number of years.

L. HARRISON MATTHEWS

GLOBAL ATOMIC WAR

On the Beach

By Nevil Shute. Pp. vi+312. (London: William Heinemann, Ltd., 1957.) 15*s.* net.

THE theme of "On the Beach" is the extinction of the human race resulting from an atomic war. Everybody dies. Just that.

When the novel opens, in Melbourne, 1962, nobody is alive in the northern hemisphere. Movements of the atmosphere are steadily carrying lethal particles southwards. Mr. Shute has deployed his remarkable imagination as engineer, naval officer and story-teller—there is a fascinating account of an atomic-powered submarine's voyage along the coast of the 'hot' North American continent—in the service of an aim which would appear to be above all a moral one. On his immense popular following this book can only inflict a haunting distress: one takes off one's hat to him.

Mr. Shute has limited his canvas: he has taken only five main characters—five very ordinary people at that; and he has pitched the emotional and dramatic tone invariably low. Until the moment when the radiation sickness comes on, everybody sticks to the tamest of domestic preoccupations; and then quietly takes a suicide pill. The effect is hypnotic, and also odd. Mr. Shute's world ends not, as the epigraph warns, with a whimper, but with a stoical silence, movingly impressive—if one were not nagged by the thought that Mr. Shute either could not or would not create someone with a wild uncontrollable reaction to catastrophe.

The moral, in so far as Mr. Shute states it explicitly, comes via his characters thus: "Maybe we've been too silly to deserve a world like this", and "The only possible hope would have been to educate them out of their silliness". Again something falls oddly, and flatly, something which tends to be characteristic of 'scientific' novels of the Wellsian kind. Like Wells, their authors, it seems to me, recognize readily in human nature "the white thread of intellect and the scarlet thread of passion"; they miss the black thread of ineradicable destructiveness. (On the other hand, 'literary' novelists of the past thirty years have tended to recognize the scarlet thread and the black, and notably to leave out intellect.) 'Silliness' would seem to mean to Mr. Shute something connected with weakness of intellect. To my mind the enemy hides deeper in us, and elsewhere; and Mr. Shute does not really get at him. But one takes off one's hat all the same.

WILLIAM COOPER

EELS

Eels

A Biological Study. By the late Prof. Léon Bertin. Pp. viii+192+8 plates. (London: Cleaver-Hume Press, Ltd., 1956.) 25*s.*

THE French title "Les Anguilles", freshwater eels, indicates that this book is a study of a single species, but this is not merely the only comprehensive account in English of the life-story and bionomics of the European eel. It aims at illustrating a number of aspects of biology and methods of research by reference to a single animal. The dramatic and once baffling life-history of the eel, as well as its economic importance, has focused attention upon it through the centuries, but it is only during the past half-century that the techniques have been developed for studying its osmotic relations during its migrations from salt to fresh water and back again, or for statistical analysis of the populations to test the homogeneity of the species, or for appreciating the role of the endocrine organs in controlling its migrations. Nor in other centuries could the problem of its sexuality and sex determination even have been defined.

A student with an elementary training in zoology to the Higher School Certificate or First Medical examination standard can read this book with profit, and come away with some understanding of the problems presented by the eel to human curiosity and of the methods of attacking them, often groping at first, but becoming more precise as understanding and technique developed. Prof. Bertin makes his study of eels also a study in the history of zoological science, presented in a literary style which enables the reader to share the excitement of discovery and emulation. Each chapter is followed by a list of references, among which we miss the complete reference to Schmidt's Royal Society paper of 1922 (although this is referred to in the text) and—an unfortunate omission for English readers—any notice of Dr. Frost's account in 1945 of the freshwater life of the eels of Windermere.

The translation runs well, but could be bettered here and there. 'Expérience', for example, should usually be translated 'experiment'. There are some serious misprints—'thiner' (*sic*) for 'plus épaisse' on

p. 95 and 'differentiation' for 'dedifferentiation' on p. 77. Aristotle's view of eel life-history was probably less naive than it is here painted. The name *Leptocephalus* was not, as the book states, first given to the larva of *Anguilla*. It was invented in 1763 by Gronovius for a larva of a conger eel sent to him by Pennant (although both, of course, were unaware of the relationship between larva and adult), long before Kaup put *L. brevirostris*, now known to be the larva of *Anguilla*, in the same 'genus'. It is worth mentioning that it was in the conger eel that the metamorphosis was first observed, by Delage in 1886, thus providing the analogy for the demonstration ten years later of the identity of *L. brevirostris* and *Anguilla* by Grassi and Calandruccio.

This book should appeal to a wide range of readers, and it is to be hoped that new editions will be called for in which not only some improvements can be made, but also the results of work still in progress may be incorporated to keep it up to date.

E. Trewavas

ECOLOGISTS IN THE LABORATORY

Microbial Ecology

Seventh Symposium of the Society for General Microbiology, held at the Royal Institution, London, April 1957. Edited by R. E. O. Williams and C. C. Spicer. Pp. ix + 388 + 6 plates. (Cambridge: At the University Press, 1957. Published for the Society for General Microbiology.) 32*s*. 6*d*. net.

The complex interlocking social structure of most natural communities of organisms is determined first by the selective action of the habitat, and secondly by the interactions of its inhabitants. It is the business of ecology to understand these relationships; all biological information can be used, and eventually must be used, by the ecologist as raw material for his study, yet the amassing of this raw material is only a first step in the elucidation of ecological relationships. Ecology has been an overworked word, and some microbial ecologists may have entertained private doubts as to whether the symposium volume here under review would represent a genuine and substantial contribution to ecology, rather than a mere rag-bag of assorted microbiological data in search of a collective title. Happily these hypothetical fears have been proved groundless by the actual event.

It is much to be hoped that ecologists in general will read this symposium volume, if only to realize that microbial ecology is now a branch of the subject in its own right, and not merely a provider of microbiological information useful, for example, to plant ecologists interested in the behaviour of roots, or in the availability of soil nutrients. Microbial ecology, owing to its greatly compressed space and time relationships, lends itself peculiarly well to laboratory study; as physiologists, biochemists and geneticists have also demonstrated, micro-organisms offer many advantages over higher animals and plants as experimental subjects.

To this volume, eighteen authors have contributed seventeen papers, distributed fairly evenly over the field of contemporary research. I should like to comment on every paper, but I must restrict myself to a short list of those contributions which I think most nearly represent the whole subject, or which consider particular aspects of general interest. Other reviewers, with other special interests, might have made a different but equally good selection; nevertheless, I am certain that any reviewer would find an excuse to mention the outstanding paper by R. Y. Stanier and Germaine Cohen-Bazire on the role of light in the microbial world. It seems impossible for Prof. Stanier to write a paper that is dull even in part, and this one fully repays the attention that its closely-reasoned arguments demand.

Although Dr. Jane Gibson's paper is concerned with nutritional aspects of microbial ecology, yet I think it succeeds better than any of the other contributions in explaining very clearly the whole subject, and this is perhaps the best paper to read by way of introduction to the others. Incidentally, it includes one of the best short histories of soil microbiology that I have read. Whereas Dr. Gibson has confined herself to the microflora of soil and other habitats, a similar broad survey serving as an introduction to microfaunal ecology has been made by Dr. J. A. Kitching in his article on the free-living Protozoa; both he and Dr. Gibson epitomize the 'oscillating process' whereby research on microbial ecology must proceed, by the alternation of field surveys and laboratory experimentation, giving progressively closer approximations to the truth.

A paper by Dr. H. T. Tribe is noteworthy not only for its description of an elegant new technique for studying the development of a succession of micro-organisms on buried cellulose film, but also for the fact that equal attention is devoted to microflora and microfauna. This is one of the most comprehensive and convincing studies of a microbial succession on a selected substrate yet to have been published. Dr. P. W. Brian's paper, on the ecological significance of antibiotic production, is certain to be widely read; here we can see how the ecologist's approach has clarified a problem of absorbing interest to many microbiologists. Only Dr. Brian, with his unique experience of the whole subject, could have discoursed with so much insight on this problem. The amount of nonsense that has been written on this subject in the past, though admittedly not by ecologists, makes the recent progress reported by Dr. Brian all the more gratifying.

Mr. F. C. Bawden's article on the role of plant hosts in microbial ecology has been as well placed in this symposium as an astringent draught in an overlong banquet—towards the end, where it is needed. I do not agree with all that Mr. Bawden has said, but I imagine that he would be dismayed if I did; he seeks not to impose agreement, but rather to provoke a more sceptical spirit of inquiry, and he has certainly succeeded in making me re-examine my own convictions. He rightly criticizes the tendency to premature generalization, and remarks that every ecological situation is best considered as though it were unique.

In the course of his paper, Dr. Kitching has incidentally deplored the "academic estrangement of bacteriology from zoology"; the publication of this symposium will at least help those to help themselves who wish to reduce the worst consequences of a cleavage that starts in the classroom. The editors, Drs. R. E. O. Williams and C. C. Spicer, are to be congratulated on the results of their unobtrusive but not inconsiderable labours.

S. D. Garrett

The Constitutional Diagrams of Alloys

A Bibliography. Originally compiled by Dr. J. L. Haughton. Second edition compiled by A. Prince. Pp. 324. (London: Institute of Metals, 1956.) 35*s.*; 5.50 dollars.

THIS bibliography is of great value to physical metallurgists, or anyone else who wants to find out quickly what work has been done on the constitution of a particular alloy system. The first edition appeared in 1942 and the present edition, which is about twice as large, covers work published up to the end of 1954, and for some journals until the middle of 1955. There are more than two hundred pages of entries on binary alloys, approximately eighty pages on ternary systems, rather more than ten and less than one, respectively, for quaternary and quinary systems, and one entry for a senary system. It is following a somewhat worn path to point out how well these figures (they are in a very rough way inversely proportional to the possible number of alloy combinations) emphasize the almost infinite scope left for investigation of alloy equilibria, especially when more than two metals are involved. A very useful feature is that the compilers have given, where possible, references to Institute of Metals abstracts. This arrangement fails for certain important ferrous systems, where few references are given; here it would surely have been appropriate to cite the abstracts of the Iron and Steel Institute. However, this is a very minor point, and in conclusion one can only admire the compilers' industry and congratulate the Institute of Metals on publishing this valuable work.

A. R. BAILEY

Chemistry

The Conquest of Materials. By Kenneth Hutton. (Pelican Book No. A353.) Pp. xii + 228 + 26 plates. (Harmondsworth, Mddx.: Penguin Books, Ltd., 1957.) 3*s.* 6*d.*

THIS book is divided into two parts, the first of which (58 pages) is devoted to pure chemistry. Holding the view that the layman likes to know something about this aspect of the science, the author goes into it sufficiently for that class of reader to grasp the meaning of such fundamental terms as element, compound, acid, base and salt. In addition, he tackles formulæ and equations, the atomic theory and the periodic system. The molecular structures appearing in this section and the numerous ones given in Part 2 will doubtless please the school pupil but puzzle the layman. The second part of the book deals with the occurrence, manufacture, properties, and the economic and industrial uses of materials, especially those which are the product of modern synthesis. Among these are foods, fuels, fibres, drugs, detergents, explosives, plastics, silicones, spermicides, vitamins and weed-killers. Dispersed through the text are the names of books going deeper into the subject in question. The illustrations consist of twenty-six half-tone plates and thirty-two figures; there are also eleven tables.

The author writes in a pleasing, conversational style and seasons his descriptions with a delightful humour. Whether expatiating on salvarsan, electricity versus coal, 'Terylene' ties and socks, or the hazard of putting an alcoholic under an anæsthetic, he is always accurate and informative. With the knowledge gained from his extensive reading, his visits to industrial works, his experience as a chemistry master and from his life at home, he has punctuated his descriptions with comments and arresting sidelights so that almost every page is replete with interesting information. Indeed, the book contains a wealth of valuable matter attractively presented. Dr. Hutton has made a great effort to explain the triumphs and the great possibilities of chemistry to the intelligent but non-scientific reader, and it has been a pleasure to review his book.

G. FOWLES

Organic Chemistry

By Louis F. Fieser and Mary Fieser. Third edition. Pp. v+1112. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1956.) 60*s.* net.

SINCE the second edition of this well-known text-book was published in 1949 there have been important advances both in experimental and theoretical organic chemistry. These have been adequately incorporated in this completely revised edition. In theory, conformational analysis, molecular orbital theory and reaction mechanisms have been treated. The elementary discussions of wave mechanics and its relations to valency theory are appropriate in a book on organic chemistry, since the full treatment will usually come in later courses in physical chemistry and the student of elementary organic chemistry needs to know something of them before this. On the factual side the book is unusually complete, with an emphasis on biochemistry which makes it especially valuable. The general treatment of classical organic chemistry is very sound, preparative methods and group reactions not being sacrificed to undue emphasis on reaction mechanisms, although these have their place. Interest is added by brief biographical sketches of past and present organic chemists; the authors say that there are 454 of these. All the formulæ are clearly set out, and the illustrations of apparatus are unusually attractive. There can scarcely be any other book covering such a wide range as this and so up to date. The concise and clear style has enabled the authors to present an astonishing amount of information in a book of reasonable size.

J. R. PARTINGTON

Heterocyclic Compounds

Edited by Robert C. Elderfield. Vol. 5: Five-Membered Heterocycles containing Two Hetero Atoms and Their Benzo Derivatives. Pp. vii + 744. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1957.) 160*s.* net.

THE fifth volume of this useful series deals with five-membered heterocyclic systems containing two heteroatoms, that is, 1 : 3-dioxolanes, pyrazoles, indazoles, imidazoles, oxazoles, benzoxazoles, isoxazoles, thiazoles and benzothiazoles. The presentation follows that established by the previous volumes; general methods of synthesis of each class are followed by a discussion of the properties and reactions pertaining thereto. This complex mass of information is methodically and clearly laid out and, although each chapter has different authorship, a pleasingly uniform presentation has been achieved. These volumes are proving most useful in filling the hitherto large gap in the systematic text-book literature of heterocyclic chemistry, although the price will no doubt deter some prospective buyers.

R. A. RAPHAEL

AN EXPERIMENT ON AIR SHOWERS PRODUCED BY HIGH-ENERGY COSMIC RAYS

By Drs. G. CLARK, J. EARL, W. KRAUSHAAR, J. LINSLEY, B. ROSSI and F. SCHERB

Department of Physics and Laboratory for Nuclear Science, Massachusetts Institute of Technology,
Cambridge, Massachusetts

PROBLEMS of interest to both the physicist and the astrophysicist single out the high-energy component of cosmic rays as a particularly promising subject of research. On one hand, the shape of the spectrum and the directional distribution of the incoming particles depend critically on the structure of the galaxy and on the mechanism responsible for the acceleration of cosmic rays. On the other hand, despite the remarkable progress of accelerators, we still have to turn to cosmic rays in order to obtain information on the fundamental problem of nuclear interactions at energies which, in the centre of mass of the colliding particles, are greatly in excess of the rest-energy of nucleons.

The cosmic-ray spectrum falls off rapidly with increasing energy. Thus particles of very high energies are exceedingly rare; for example, the rate of arrival of particles with more than 10^{16} eV. energy is of the order of one per year per square metre. Hence direct methods of detection are ruled out, and the only practical approach is the study of the giant showers that are produced in the atmosphere by high-energy cosmic-ray particles.

The essential features of this phenomenon are well known. After a comparatively short path through air, the primary particle collides against an atomic nucleus, producing a number of high-energy secondary particles. Among these are π^0-mesons, which immediately decay into photons, and nuclear-active particles (charged π-mesons, nucleons, etc.), which go on to produce further interactions, so that a nuclear cascade develops. At each step a certain fraction of the energy goes into photons via the decay of π^0-mesons; photons initiate electronic cascades and soon electrons and photons become the dominant component of the shower. Some of the charged π-mesons, however, decay before interacting and thus contribute an appreciable number of μ-mesons to the shower. Scattering in air spreads the shower particles over a wide area, with a density that decreases gradually as the distance from the shower core increases.

Our group has been operating, intermittently since July 1955, and continuously since June 1956, an experiment on large air showers. Unlike previous experiments of a similar nature, our experiment is designed to provide sufficient information on each individual shower to determine accurately the size of the shower and the direction of arrival of the initiating particle.

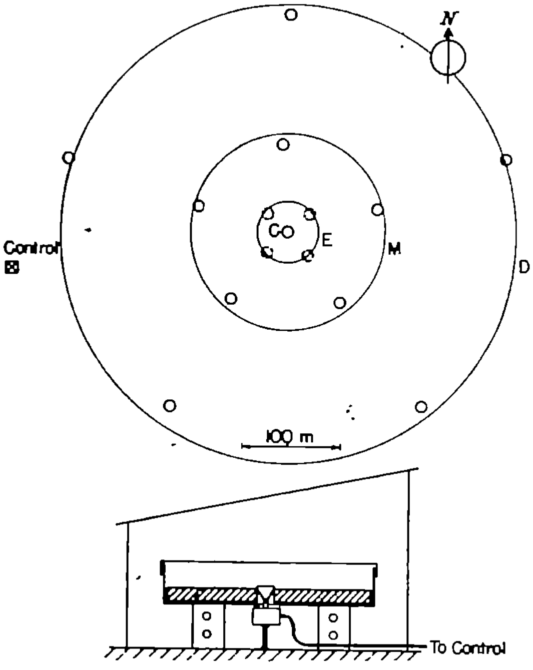

Fig. 1. Detector array and schematic diagram of a scintillation counter

We use as detectors plastic scintillators in the shape of disks 105 cm. in diameter and 10 cm. thick. Each scintillator is viewed by a single Dumont 5-in. phototube. The detectors are arranged in a circular area of about 460 m. in diameter, in the grounds of the Agassiz Astronomical Station of Harvard University at Cambridge, Massachusetts, 183 m. above sea-level (Fig. 1). For most of the time we have used eleven detectors (C, M and D in Fig. 1), but during a short period we had four additional detectors placed near the centre of the array (E in Fig. 1) in order to extend our measurements to showers of smaller size than those which could be recorded in the main experiment. The detectors are connected by cables to separate oscilloscopes, which are situated in a control station and arranged one next to the other so that they can be photographed by a single camera. The sweeps of the oscilloscopes are triggered simultaneously whenever ten or more shower-particles traverse each of at least three among a pre-selected group of detectors, within a time interval of about 3 microseconds.

From preliminary experiments conducted at our laboratory[1], it is known that at any one instant of time practically all shower particles lie within a disk of only a few feet in thickness, perpendicular to the direction of propagation of the shower, that is, to the direction of arrival of the initiating particle. Fig. 2 shows schematically a shower front approaching the counter-array, and illustrates the principle of our method. It is clear that the differences between the times of arrival of the shower front at the various detectors depend on the direction of the shower axis, whereas the pulse heights (which are proportional to the numbers of shower particles traversing the detectors) depend on the location of the shower core,

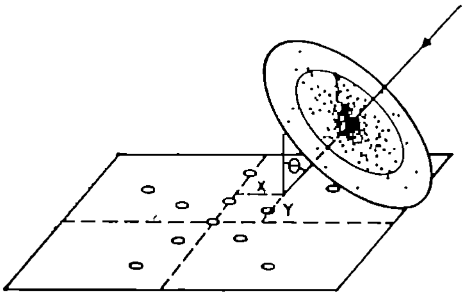

Fig. 2. Shower front approaching the detector array

the lateral distribution of shower particles and the total number of particles in the shower.

The actual evaluation of the observations proceeds as follows. From a least-squares analysis of the time delays, we first determine the direction of the shower axis; the uncertainty in the measurement of angles by this method turns out to be of the order of 5°. Using this result and the pulse height information, we then determine the total number of shower particles N, the co-ordinates X and Y of the shower centre, and the shape of the lateral distribution function. For this determination we assume that the density of particles at the distance r from the core is given by:

$$f(r) = \frac{N}{2\pi r_0} \frac{\exp(-r/r_0)}{r} \qquad (1)$$

where r_0 is a free parameter, and compute the values of N, r_0, X and Y which minimize the mean square deviation of the observed from the computed densities. (It was anticipated from existing experimental and theoretical information, and it has been confirmed by our results, that with a suitable choice of r_0 equation 1 is a good approximation of the lateral distribution function.) The computations are carried out by means of a fast electronic computer.

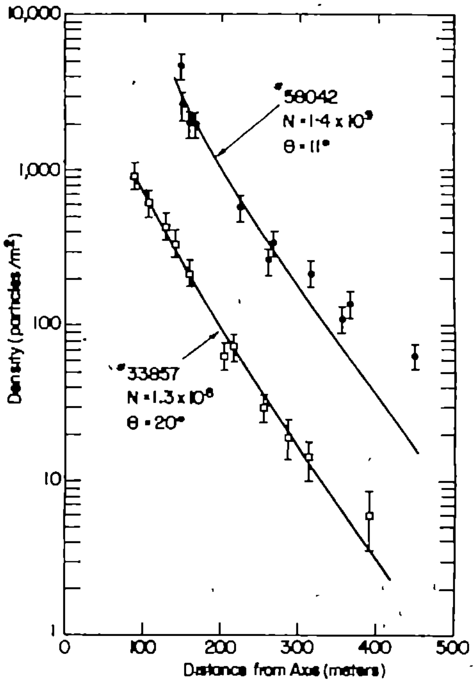

Fig. 3. Lateral density distributions of two large showers

We calibrate the detectors by measuring the distribution in height of pulses produced by single cosmic-ray particles. The overall performance of the equipment is periodically checked by an automatic device which, every 7 hr., plots the bias curve of each detector. In addition, the counting rates of all detectors for pulses greater than those corresponding to the passage of 10 particles are continuously recorded. In what follows we give a preliminary account of the results obtained to date.

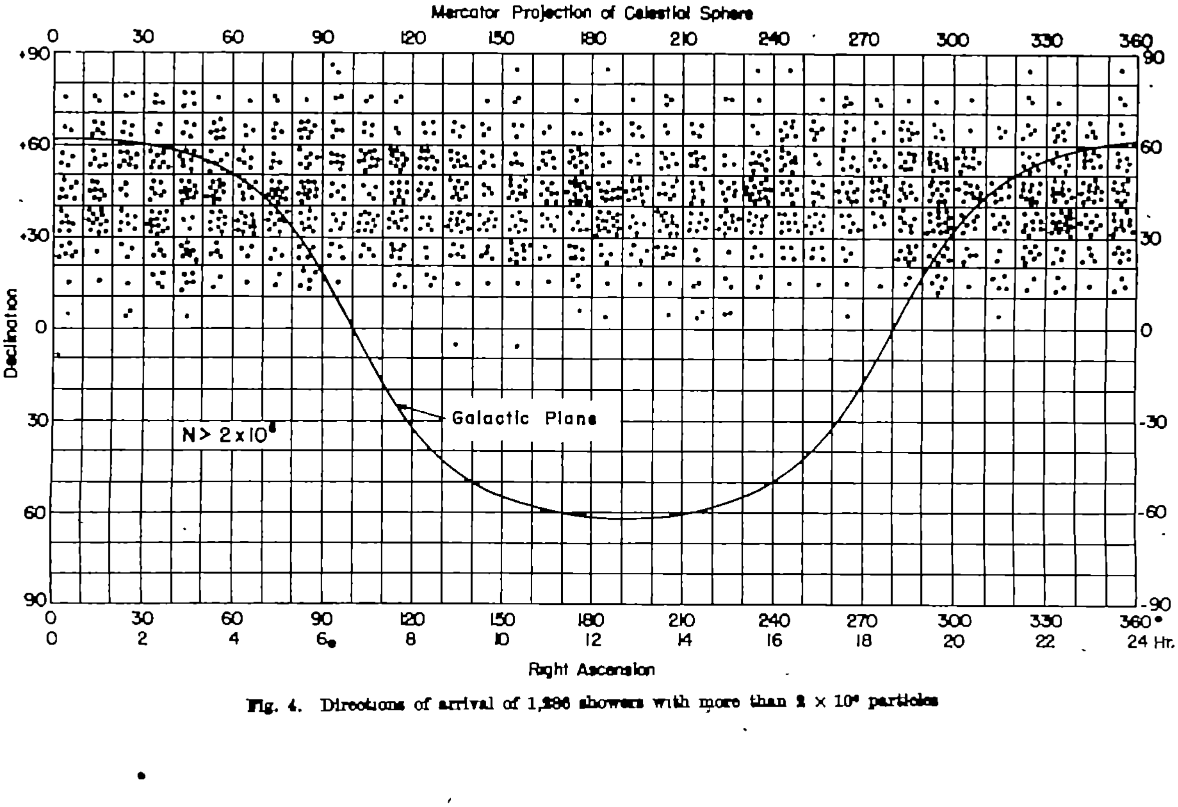

Fig. 4. Directions of arrival of 1,386 showers with more than 2 × 10⁶ particles

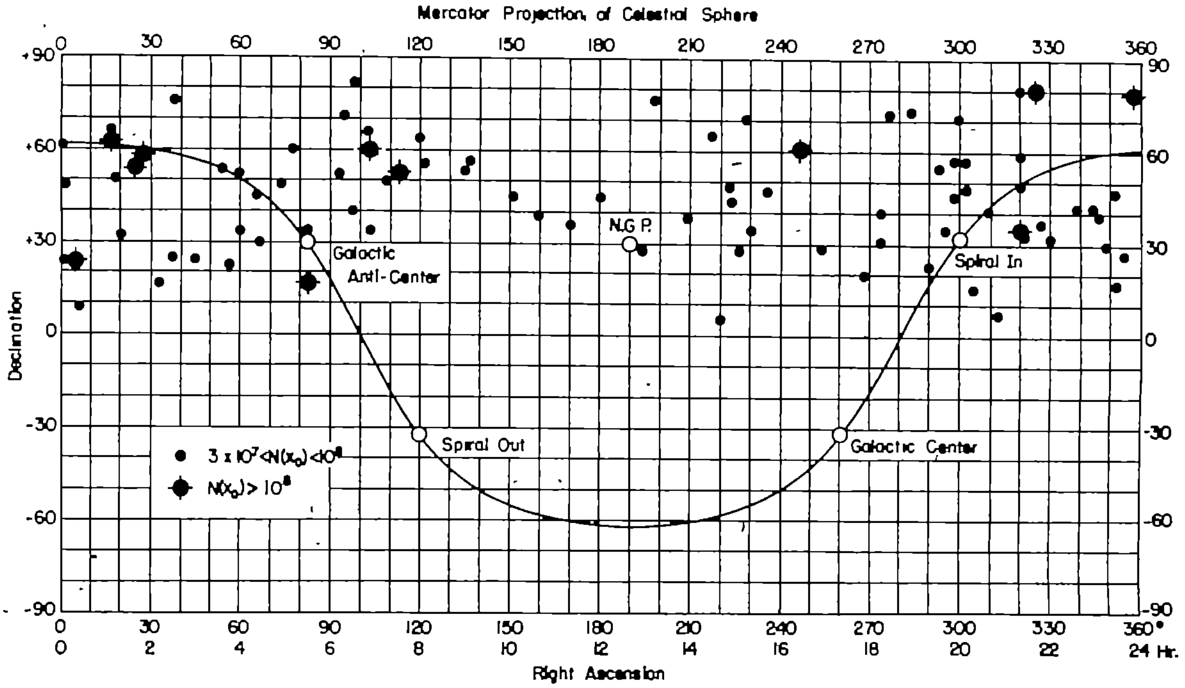

Fig. 5. Directions of arrival of 87 showers with more than 3×10^7 particles

Largest Recorded Shower

Showers with more than 10^8 particles are recorded by our array at the rate of about one per month. Showers of comparable size are currently recorded by the Harwell group with an array of Geiger counters covering an area of 0·47 km.^{2} (W. Galbraith, private communication). The largest shower recorded so far had $1{\cdot}4 \times 10^9$ particles and came at a zenith angle of 11°. The energy of the primary particle responsible for this shower was probably close to 10^{19} eV. and could not have been smaller than 2×10^{18} eV., even allowing for a large fluctuation in the longitudinal development of the shower. The lateral density distributions for this shower and for another large shower are shown in Fig. 3.

Distribution in the Directions of Arrival

Fig. 4 summarizes the results obtained so far for showers with more than 2×10^6 particles. Each point represents the direction of arrival of an individual shower, on a Mercator projection of the celestial sphere. Atmospheric absorption is responsible for the fact that the experimental points lie within a narrow band of latitude, centred at 42° (the latitude of our station). Along this band there is no significant variation in the density of points, and in particular there is no tendency for the points to cluster about the galactic plane, which confirms previous results indicating that the primary particles are distributed isotropically. Fig. 5 shows a similar

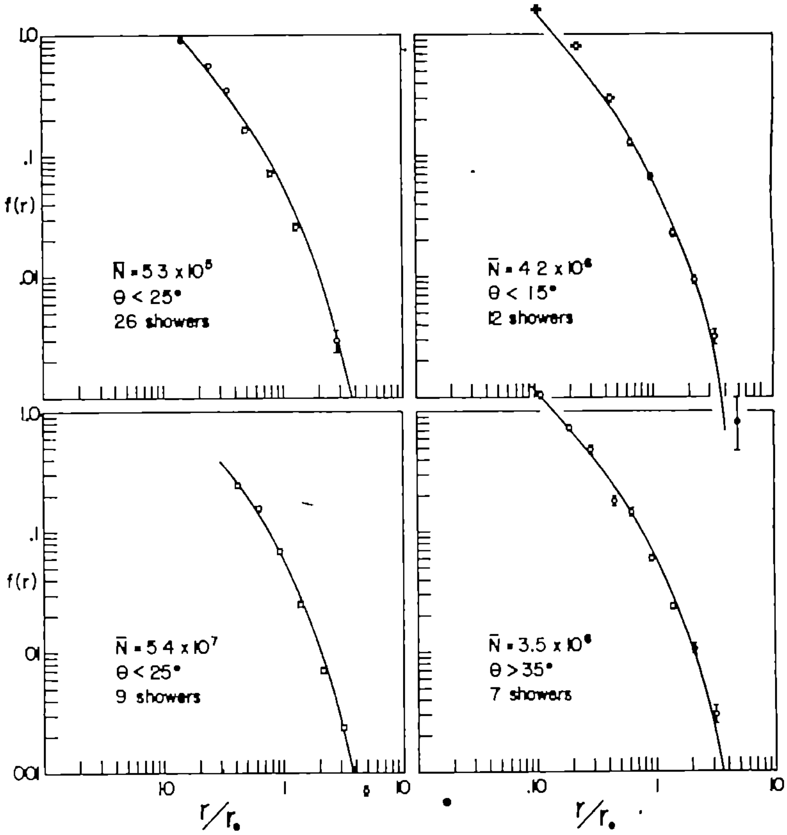

Fig. 6. Composite lateral distributions for several groups of showers ($r_0 = 79$ m.); the curves represent $f(r)$ defined by equation 1

plot for the largest showers observed in the experiment. These showers were selected according to their 'equivalent vertical size' $N(x_0)$, that is, the size which a shower would have had if it had traversed the atmosphere vertically (see below). The map shows that we have recorded more showers from directions close to the galactic plane than from directions near the north galactic pole (N.G.P. on the map). The statistics so far available are very meagre, however, and a definite conclusion concerning a possible lack of isotropy of these very large showers must await further observations.

Lateral Density Distribution

To answer the question as to whether or not the lateral density distribution varies systematically with N or θ, we selected three groups of showers with N near $4 \cdot 5 \times 10^5$, $4 \cdot 2 \times 10^6$ and $5 \cdot 4 \times 10^7$, respectively, coming from approximately vertical directions and one group of showers with N near $3 \cdot 5 \times 10^6$ coming from large zenith angles. For each of the four groups we computed the average normalized density distribution, as a function of the distance r from the shower axis. The normalization factor applied to each density measurement was r_0^2/N, where N was the computed size of the shower. The results are shown in Fig. 6, from which it appears that there is no marked dependence of the lateral distribution function on either the size N or the zenith angle θ. In all cases the experimental distribution agrees with that given by equation 1 with $r_0 = 79$ m. This distribution, incidentally, is practically identical (up to about 300 m.) with that given by the theory of Nishimura and Kamata[2] for an 'age parameter' $s = 1 \cdot 4$. This result appears to be consistent with the idea that the development of the shower is mainly determined by the nuclear cascade, and that the electronic component is more or less in equilibrium with the nucleonic component. A. T. Abrosimov *et al.*[3] have drawn a similar conclusion from their experimental observations showing that the lateral distribution is essentially independent of shower size or altitude of observation.

Fig. 7 shows a composite plot of observed versus calculated densities made from the results for about thirty showers picked at random. The abscissa is the observed density at a particular place in a given shower and the ordinate is the calculated density based on the least squares analysis of the density results for that shower. (The points on the horizontal axis represent cases where no pulse was detected from the counter.) The broken lines indicate the magnitude of the standard statistical fluctuations corresponding to the Poisson distribution. It can be seen that Poisson fluctuations account for the scatter of the points up to densities of about 100 particles/m.². Above this density (corresponding to a Poisson fluctuation of 10 per cent) the instrumental errors are the most important source of scatter. Abnormal showers do not appear more frequently than about one per hundred. This means that for most showers we can accurately determine both the position of the centre and the total number of particles. In order to test the response of the experimental arrangement and the accuracy of the method of analysis, we analysed several 'artificial' showers assuming random-density fluctuations obeying a Poisson distribution. From the results of these tests, we found that for showers with cores lying within 160 m. of the centre of the array, the maximum uncertainty in the location of the core is about 10 per cent of the distance from the centre, and the maximum uncertainty in the determination of N is about 20 per cent.

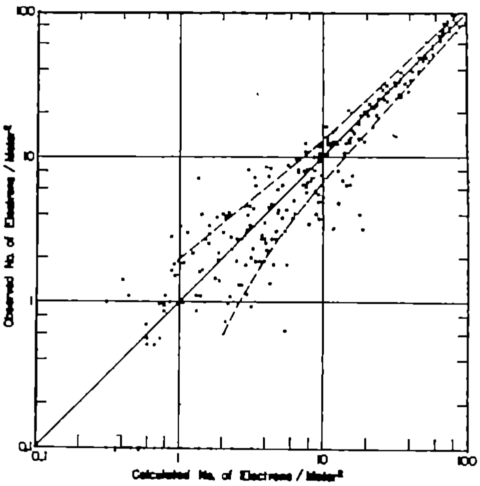

Fig. 7. Plot of the density fluctuations observed in thirty showers

THE CANADA COUNCIL FOR THE ENCOURAGEMENT OF THE ARTS, HUMANITIES AND SOCIAL SCIENCES

THE Canada Council for the Encouragement of the Arts, Humanities and Social Sciences was established by an Act of February 15, 1957, as a corporation consisting of a chairman, vice-chairman and nineteen other members appointed by the Governor-in-Council. The chairman and vice-chairman are appointed for terms not exceeding five years and the other members for terms of three years. Its principal officers are the director and associate director, appointed by the Governor-in-Council, and the treasurer and secretary. The continuing work of the Council is financed by income from a permanent endowment fund of 50 million dollars from the Consolidated Revenue Fund. From the same source a University Capital Grants Fund has also been established. The Council is advised in the management of investments under the Canada Council Act by an investment committee consisting of the chairman of the Council, another member designated by the Council and three members appointed by the Governor-in-Council.

The objects of the Council are to foster and promote the study and enjoyment of, and the production of works in, the arts, humanities and social sciences, and in furtherance of these objects the Council may assist and co-operate with other organizations with similar objects, establish scholarships and fellowships for study or research in these fields or make awards for outstanding achievements therein. It can also sponsor exhibitions, performances or publications, arrange exchanges of persons or information with other countries or for the representation and interpretation of Canadian arts, humanities and social sciences abroad, and the Governor-in-Council may assign the Canada Council functions and duties in relation to the United Nations Educational, Scientific and Cultural Organization. The purpose of the University Capital Grants Fund is to enable the Council to make grants to universities and similar institutions of higher learning for building projects up to half the total expenditure on any one project, to a total for any one province proportional to the population of that province.

At the first meeting of the Canada Council on April 30 and May 1, the proceedings of which were opened by the Governor-General, the chairman of the Council, the Hon. Brooke Claxton, said that the Canada Council has been established to help the advance of the nation in its artistic expression so that they could, in the words of one of its founding fathers, Thomas D'Arcy McGee, "Lift ourselves to the level of our destinies". The University Capital Grants Fund is intended to assist the expansion of Canadian universities over the next ten years. The chairman said that the income of some 2 million dollars from the endowment fund is to be expended in no narrow interpretation of the expression 'arts and humanities', and that the term 'social sciences' will be taken to include economics, psychology, sociology, political science, geography and law. It is a new venture for Canada, although on research, scholarships, the Canadian Broadcasting Corporation and other organizations, the Federal Government is spending nearly 60 million dollars a year, and learned societies, such as the Canadian Social Science Research Council and the Humanities Research Council of Canada, have been doing fine work for years. He believes the initial tasks will be to discover and assist Canadian artists and thinkers of outstanding promise, and to encourage, train and assist university professors and other instructors in the arts, humanities and social sciences. The vice-chairman, the Very Rev. Georges-Henri Lévesque, also spoke, stressing the pre-eminence of the intellectual concepts and the arts among the cultural and spiritual values of a people for the expression of the soul of the community.

FLOW OF STEAM–WATER MIXTURES AT HIGH PRESSURES

By R. W. HAYWOOD

Engineering Laboratory, University of Cambridge

IN a research project being carried out in the University Engineering Department at Cambridge, a study is being made of the pressure drop and the flow conditions of a steam–water mixture flowing along heated and unheated pipes at pressures up to the critical region. This is a field in which few exact experimental data are available, and which is of importance in the design of high-pressure boilers for power stations and evaporative heat exchangers for nuclear power plant. A knowledge of the pressure drop is essential in estimating the flow-rates through the individual tube circuits of a boiler, and a study of the flow conditions will enable a better understanding to be obtained of the fundamental mechanism of two-phase flow. The project is sponsored by the Water-Tube Boilermakers' Association, and provides an interesting example of close co-operation between an academic body and a commercial trade organization. Not only is the work carried out under the guidance of a joint technical advisory panel comprising representatives of the Department of Engineering at Cambridge and of the member companies of the Association but, in addition to the graduate staff working on the project, numerous research assistants from the staffs of the member companies have been seconded to work at Cambridge for extended periods.

This experimental work was proposed by the University as an extension to some studies previously carried out in the Engineering Laboratory. These studies[1] resulted in a unification of three existing, but previously conflicting, theories of circulation in water-tube boilers known as the 'hydraulic', 'thermodynamic' and 'expansion' theories of circulation, but it was indicated that further experimental data were required before circulation-rates could be reliably predicted.

The plant is installed out of doors from considerations of safety, but all instrumentation is carried to a control-room. The test circuit comprises a continuously recirculating closed system, in which the high-pressure fluid is circulated by a glandless electromersible pump. This pump draws saturated water from a steam drum and delivers it through a metering orifice, control valve and preheater to the test-section, which can be mounted in either a horizontal, inclined or vertical position. The test-section is 24 ft. long, with pressure tappings at 8-ft. intervals, and can be heated over a part or the whole of its length. From the test-section the steam–water mixture passes to a water-jacketed condenser, and thence through a reheater back to the drum.

The preheater comprises a special 'Pyrobar' immersion heater, and brings the water to its local saturation temperature at entry to the test-section, so that it is known precisely that the water entering the test-section is just on the point of boiling. Since the test-section inlet is some distance below the drum, the achievement of local saturation conditions is achieved with the aid of differential pressure and temperature measurements between test-section inlet and the drum, where saturation conditions are known to obtain. Readings of differential pressure, including those giving the pressure drop on the test-section itself, are made on direct-reading mercury and 'Igema'-fluid manometers in spite of the high pressure employed. These manometers, and the high-sensitivity thermo-couples used for differential temperature measurement, have been designed and constructed in the University Engineering Laboratory at Cambridge.

The test-section is heated electrically by means of low-frequency, three-phase, induction heating utilizing a special form of water-cooled winding, and employing a coating of copper sprayed on to the thick-walled steel pipe constituting the test-section. The heaters have been designed and constructed in the Laboratory in consultation with the patentees of certain features incorporated in the design. The heaters give a uniform power input over the heated length of the test-section, and by alternative methods of series and parallel connexion of the coils and groups of coils constituting the winding, the total power input may be varied over a considerable range in a number of steps without the use of a voltage regulator. The water-cooling provides a ready means of determining the lost power, the small rise in temperature of the inductor cooling water being measured by triple-point differential thermocouples.

In addition to measurements of drop in pressure, the flow conditions are being studied with the aid of a gamma-ray device supplied on loan by the Atomic Energy Research Establishment at Harwell. In this device, a beam of gamma-rays from a radioactive isotope of cæsium is passed transversely through the pipe at test-section outlet. An ionization chamber placed diametrically opposite the source gives a measure of the emergent radiation, which is a function of the density of the fluid cross-section at the scanning point. With this determination of the apparent density of the fluid and a knowledge of the flow-rate and heat input in the test-section, the respective velocities of the steam and water phases at the scanning point may be estimated, for the steam and water do not generally flow along the pipe as a homogeneous mixture. This information is also necessary for the respective drops in pressure due to acceleration and wall friction in the horizontal pipe to be separately estimated. Provision is being made for the installation of further scanning points at intermediate positions along the length of the test-section when it is in the vertical position, since density determination is then more important for an analysis of the pressure drop. As there is little space between the induction heating units at these intermediate points, small ionization chambers, filled with argon under pressure, are being developed to provide higher sensitivity.

Tests have been completed with a test pipe of 1 in. bore in the horizontal position. These tests have been made at varying flow-rates and heat inputs, and at pressures of 250, 600, 1,250, 2,100 and 3,000 lb. in.^{2}. The results of these tests, together with those obtained with other pipe sizes at various inclinations, will be published in due course. Preparations are at present being made for tests on the 1-in. pipe in the vertical position.

HAZARDS ASSOCIATED WITH THE DEVELOPMENT OF WEAPONS OF MASS DESTRUCTION

INTERNATIONAL MEETING OF SCIENTISTS

TWO years ago a statement, referred to as the 'Russell–Einstein Appeal', was issued under the signatures of its sponsors and eight other scientists, directing attention to the hazards which would face humanity should another world war break out, a war in which the widespread use of nuclear weapons would be almost certain. The appeal suggested that a meeting of competent scientists ought to take place, to make a true and independent assessment of the dangers.

Through the initiative of Lord Russell and the generous hospitality of Mr. Cyrus Eaton, such a meeting was held in the fishing village of Pugwash, Nova Scotia, during July 6–11. About forty invitations were issued, so chosen as to ensure that the composition of the Conference would be representative of a wide range of opinion on social, economic and political matters, with members competent in the scientific disciplines relevant to the discussion. Twenty-two scientists were able to accept the invitation, and at the end of the meeting a statement was issued, the substance of which is as follows.

In a brief preamble an outline is given of the background to the meeting, and a summary of the most important developments since the original Russell–Einstein appeal was issued. The statement continues: "The general belief that a full-scale nuclear war would bring universal disaster upon mankind, and the recognition that it is technically possible for both the two great contending groups of powers to visit any desired degree of destruction upon an enemy, as well as certain political developments, have created an atmosphere in which it was possible for us to meet, and to discuss dispassionately, many important and highly controversial issues".

The main work of the meeting was centred around three principal topics: (1) the hazards arising from the use of atomic energy in peace and war; (2) problems of the control of nuclear weapons; and (3) the social responsibility of scientists. Three committees were established to give detailed consideration to these topics. In presenting the findings, the signatories remark that the international problems which have arisen with the development of atomic energy are of two kinds—technical and political. Men of science can discuss with special competence only the scientific and technical implications of atomic energy; but their discussions can only be fruitful if they take account of the political problems which form the background to international negotiations. In formulating their conclusions, they state that they have attempted to avoid any exacerbation of the differences between the Powers which might follow, for example, from emphasis on technical considerations unwelcome to one or another of the two groups of Powers.

The committee on the hazards associated with the application of atomic energy found that estimates of the effect of 'fall-out', carried out independently in Great Britain, Japan, the United States and the U.S.S.R., were in good agreement; it reached the conclusion that the dangers from the test explosions carried out hitherto are small compared with those to which mankind is subject from natural causes.

Nevertheless, because of the world-wide distribution of fission products, and the fact that some areas may be subject to effects much above the average, close attention to the dangers should be maintained, especially if tests of bombs which give large radioactive 'fall-out' continue to be made.

The studies of the hazards of test explosions permitted a closer examination to be made of the probable consequences of an unrestricted war with nuclear weapons; this led to the unquestioned conclusion that such a war would represent a disaster of unprecedented magnitude. "In the combatant countries, hundreds of millions of people would be killed outright, by blast, heat and ionizing radiations, at the instant of the explosion, whether the so-called 'clean' or 'dirty' bombs were employed." If 'dirty' bombs were employed, "additional hundreds of millions would die from the delayed effects of radiation from local 'fall-out'—some from direct radiation injury, and some in later generations from genetic effects". Large-scale genetic injury might also follow from global 'fall-out'.

The committee which considered problems of control reached the conclusion that the principal objective of all nations must be the elimination of war, and the threat of war, from the life of mankind. For this purpose, it is necessary to reduce tension among the nations; to promote mutual understanding among the peoples; to strive for the ending of the arms race; and to provide an adequate control system so as to give substantial protection, and permit the development of mutual confidence. "It is unrealistic to depend upon any sudden increase in mutual confidence; it is more likely to grow from small beginnings. In this situation, even small agreements covering limited fields could be of great importance."

The committee which discussed the responsibilities of scientists in the modern world summarized its findings under eleven headings. Among many points of importance, two deserve particular attention: Point 9 states that "Tradition tends to place the emphasis in the education of youth on separate ideals of single nations, including the glorification of war. The atomic age urgently requires a modification of these traditions. Without abandoning loyalty to the national heritage, or to the fundamental principles of the different societies, education must emphasize the fundamental and permanent community of the interests of mankind, in peace and co-operation, irrespective of national boundaries and differences in economic or political systems"; and Point 11, "Science develops most effectively when it is free from interference by any dogma imposed from the outside, and permitted to question all postulates, including its own. Without this freedom of scientific thought, and the freedom to exchange information and ideas, full utilization of the constructive possibilities of science will not be possible".

The conference was unique in that never before had a group of scientists, so widely representative, met to discuss topics of such general importance. It is remarkable that it was possible to issue a statement, with such a measure of agreement, on many issues which might have appeared highly controversial and unlikely to receive general support. The statement concludes by giving expression to the unanimity in the conference on fundamental aims: "We are all convinced that mankind must abolish war or suffer catastrophe; that the dilemma of opposing power groups and the arms race must be broken; and that the establishment of lasting peace will mark the opening of a new and triumphant epoch for the whole of mankind. We earnestly hope that our conference may make a modest contribution to these great aims".

The signatories were: *Australia*, Prof. M. L. E. Oliphant; *Austria*, Prof. H. Thirring; *Canada*, Dr. G. Brock Chisholm; *China*, Prof. Chou Pei Yuan; *France*, Prof. A. M. B. Lacassagne; *Great Britain*, Prof. C. F. Powell, Prof. J. Rotblat; *Japan*, Prof. I. Ogawa, Prof. H. Yukawa, Prof. S. Tomonaga; *Poland*, Prof. M. Danysz; *U.S.A.*, Prof. D. F. Cavers, Prof. H. J. Muller, Prof. P. Doty, Prof. E. Rabinowitch, Prof. W. Selove, Prof. V. Weisskopf; *U.S.S.R.*, Academician A. M. Kuzin, Academician D. F. Skobeltzyn, Academician A. V. Topchiev.

OBITUARY

Mr. R. G. K. Lempfert

METEOROLOGISTS learned with great regret of the sudden death on June 24 of R. G. K. Lempfert, formerly assistant director of the Meteorological Office. Sir Napier Shaw recorded that when he became the effective head of the Meteorological Office nearly sixty years ago, one of its peculiarities was that none of the members of the staff had had any preliminary scientific training. (This does not mean that they lacked ability—far from it. For example, out of a small staff one became Mayor of Camberwell and another Mayor of Fulham.) Shaw's first step to remedy the obvious defect was to appoint Lempfert, who had taken a 'first' at Cambridge in both parts of the Natural Science Tripos, in 1896 and 1898, to a specially created post of scientific assistant. Not surprisingly, this appointment in 1902 has been abundantly justified both by the investigations Lempfert undertook or shared and by the influence he exerted on meteorological administration and operational meteorology for a quarter of a century.

Lempfert's scientific investigations covered a wide field. Many were made in collaboration with others. He began with studies of London fog and of a fall of 'red rain', found to be due to dust the track of which was traced back around the Iberian peninsula to North Africa. Soon he was tackling, with Shaw, the "Life History of Surface Air Currents". Lempfert's part was mainly the critical examination and co-ordination of the records and observations from which the divergent sources and tracks of the air in a number of typical or outstanding meteorological situations could be identified and delineated. But he also made a separate special study of the line-squall, one of the most significant and qualitatively foreseeable meteorological phenomena—the simultaneous occurrence of squalls, sometimes of great violence, along a line which may be hundreds of miles long and which may advance at 5 or at 50 miles per hour. These investigations, revealing as they did unsuspected discontinuities in the earlier simplified structure of 'depressions', paved the way for the

Norwegian development of frontal meteorology, the dominating influence on macro-meteorology in the period between the two World Wars. In fact, the first use of the word 'front' in its present technical sense appears to have been in the second paper on line-squalls (Lempfert and Corless, 1910).

The expansion of the Meteorological Office during and after the First World War and its transference to the Air Ministry involved Lempfert in much administrative work, but he maintained a lively interest in the scientific work both of the Meteorological Office and of the Royal Meteorological Society, of which he was president during 1930–32 and the *Journal* of which he edited for many years.

After his retirement in 1938 he was responsible, as an executor of Sir Napier Shaw's will, for the establishment of the Napier Shaw Meteorological Library in the Cavendish Laboratory at Cambridge; and for the selection and publication in one volume of the "Selected Meteorological Papers of Sir Napier Shaw". This included the "Life History of Surface Air Currents", which had long been out of print. It was a classic, essential to a meteorological library, and many such libraries had been unable to get a copy.

Lempfert was born in Manchester on October 7, 1875, the son of R. B. and Olga (née von Pein) Lempfert. They were both musical and Lempfert's recreation was music; an incident illustrates his love of it. He was the first to give a course of meteorological lectures for airmen—at the Central Flying School, Upavon, when Trenchard was commandant. The honorarium, less the cost of a dinner to celebrate with his friends the successful conclusion of the course, was spent in the purchase of a rare violin. A few years later he married, in 1916, a distinguished violinist, Marjorie Hayward. She predeceased him. Lempfert was practically bilingual, speaking English and German with equal facility, a great asset at international meetings, where he was held, rightly, in the highest esteem. In the Meteorological Office his courtesy was proverbial; loyalty and unselfishness were, with him, innate qualities. E. Gold

NEWS and VIEWS

Mount Wilson and Palomar Observatories : Dr. S. B. Nicholson

Dr. Seth B. Nicholson, of the Mount Wilson and Palomar Observatories, retired on July 1. He obtained his Ph.D. from the University of California in 1915 and in the same year joined the staff of the Mount Wilson Observatory, where he investigated the orbits of several of Jupiter's satellites, the ninth of which he had discovered at the Lick Observatory in 1914. In collaboration with Dr. Edison Pettit, he developed a very sensitive vacuum thermocouple, which they used for measuring the total radiation and surface temperatures of stars, planets and the Moon. Studies of the rate of cooling of the Moon's surface during an eclipse demonstrated its low conductivity; their results suggest the presence of a layer of dust and the absence of an atmosphere, in agreement with optical and radio observations. In the late 1930's, and again in the early 1950's, Dr. Nicholson returned to the observation of Jupiter's satellites; he discovered the tenth, eleventh and twelfth of these and determined the positions necessary to fix their orbits. Dr. Nicholson is also an eminent authority on solar phenomena, and supervised the systematic collection of magnetic and other data on sunspots. He has made detailed studies, in collaboration with Dr. Oliver Wulf, of the California Institute of Technology and the United States Weather Bureau, of solar-terrestrial relations. Dr. Nicholson is a member of the U.S. National Academy of Sciences, the American Astronomical Society and the Astronomical Society of the Pacific.

Dr. M. L. Humason

Dr. Milton L. Humason, secretary of the Mount Wilson and Palomar Observatories since 1948, retired on July 1 after a most remarkable career. He joined the Mount Wilson Observatory in 1917, first as janitor and then as night assistant, and showed such skill as an observer that he was appointed to the staff of investigators in 1922. His unique gift was an unusual proficiency in photographing the spectra of very faint objects. Following the late Dr. Edwin Hubble's discovery in the 1920's of the major part played by the extra-galactic nebulæ in the structure of the universe, Humason turned to the study of these objects and soon accumulated spectra of numerous galaxies at various distances. This material led Hubble to his famous velocity–distance relation and to the observational basis of the concept of the expanding universe. For the following quarter-century, Dr. Humason continued to devote most of his attention to this problem: improvements in photographic emulsions and in spectrograph design, together with the completion of the 200-in. Hale telescope, enabled him to push his observations to much fainter, more distant galaxies, many of them too faint for visual guiding on the spectrograph slit. For these, Dr. Humason had to develop elaborate 'off-set' procedures to keep the invisible images accurately on the slit throughout long exposures. His studies culminated in the publication in 1956, together with Dr. N. Mayall and Dr. Allan Sandage, of the velocities of more than nine hundred galaxies, some being as great as one-fifth the velocity of light. Dr. Humason received his Ph.D., *honoris causa*, from the University of Lund in 1950 and is a member of the American Astronomical Society, the Astronomical Society of the Pacific, and the International Astronomical Union. He was elected an Associate of the Royal Astronomical Society in April 1957.

Chemistry in Manchester : Prof. R. N. Haszeldine

The Councils of the University of Manchester and the Manchester College of Science and Technology have approved the appointment of Dr. R. N. Haszeldine to the chair in chemistry in the Faculty of Technology as from October 1. He succeeds Prof. H. N. Rydon, who is going to the University of Exeter (see *Nature*, April 20, p. 807). Dr. Haszeldine, who is thirty-three years of age, was educated at the Stockport Grammar School, and entered the University of Birmingham with a John Watt Memorial Scholarship in 1942. He graduated with first-class honours in chemistry in 1944, and two years later obtained his Ph.D. In 1947 he went to the University Chemical Laboratory, Cambridge, becoming eventually assistant director of research in organic and inorganic chemistry. He qualified for the degree of D.Sc. (Birmingham) in 1955. Dr. Haszeldine was awarded the Meldola Medal by the Royal Institute of Chemistry in 1953. He is the author or joint author of a very large number of papers arising out of his research work and is joint author with Dr. A. G. Sharpe of "Fluorine and its Compounds" (1951). Outside the laboratory, he has interested himself in the applications of chemistry in industry and has invented several industrial processes.

Capper Pass Awards in Metallurgy

The adjudicating committee for the Capper Pass awards, representing the Councils of the Institution of Mining and Metallurgy and of the Institute of Metals, has made the following awards in respect of papers published in the *Transactions of the Institution of Mining and Metallurgy* and the *Journal of the Institute of Metals* for the year 1956: £120 to Dr. J. M. Fletcher, Dr. D. F. C. Morris and Mr. A. G. Wain for a paper on "Outline of a Solvent Extraction Process for the Purification of Niobium from Ores or from Ferro-Niobium"; fifty guineas to Mr. J. A. Grainger for a paper on "The Deep Drawing and Spinning of Sheet Metal, with Particular Reference to Non-Ferrous Materials"; fifty guineas to Mr. J. Fielding for a paper on "Rubber Pressing". These awards are made from a fund placed at the disposal of the Councils of the two Societies by the Directors of Capper Pass and Son, Ltd., for the encouragement of the publication of scientific and technical papers dealing with processes and plant used in extraction metallurgy and on the subject of assaying and of papers and processes used in all branches of the non-ferrous metal industry.

Collaboration between Britain and Norway in Atomic Energy Developments

The United Kingdom Atomic Energy Authority and the Norwegian Institute for Atomic Energy have recently signed an agreement for co-operation in connexion with the Norwegian Halden Reactor Project. This project is concerned with an experimental reactor, scheduled to start operation early in 1958, which is designed to produce process steam suitable for wood-pulp mills and other industrial uses. The United Kingdom Authority has undertaken to supply the initial charge of uranium fuel elements for the reactor. The Norwegian Institute and the Authority will also co-operate in a research programme with the view of developing suitable fuel elements for later charges for the reactor. The agreement provides for the Authority to have access to the reactor design and to the operating experience obtained from this important experiment.

The Meteorological Committee

The Secretary of State for Air, Mr. George Ward, M.P., announced in the House of Commons on June 28 last that he had accepted a recommendation of the Brabazon Committee that the Meteorological Committee, which was formed in 1919 and included representatives of various departments with a user interest in meteorology, should be replaced by an advisory committee all members of which should be outside the Government Service. The new Committee will keep under review the progress and efficiency of the Meteorological Office and the broad lines of its current and future policy. It is constituted as follows: Lord Hurcomb (*chairman*); Sir Austin Anderson; Sir David Brunt; Sir Charles Normand; Colonel N. V. Stopford Sackville.

Element 102

Element No. 102, for which the name 'nobelium' has been proposed, was recently synthesized by a joint Swedish, American and British team at the Nobel Institute for Physics in Stockholm (see *Nature*, July 20, p. 120). It has been announced that there will be a special meeting of Section B (Chemistry) of the British Association, on September 9 at 2.30 p.m., when Mr. H. A. C. McKay and Dr. J. Milsted, of the Atomic Energy Research Establishment, Harwell, the latter of whom was a member of the Swedish–American–British team of discoverers of the new element, will describe this work.

Oil Consumption in the United Kingdom

Figures recently published by the Petroleum Information Bureau (U.K. Petroleum Industry Statistics relating to Consumption and Refinery Production, 1955 and 1956. Pp. 10. London: Petroleum Information Bureau, 1957) show that, despite petrol rationing and restrictions during the October–December quarter due to the Suez crisis, the oil consumption in Britain for 1956 rose considerably to a total of 25,233,049 tons, representing an increase of 8·5 per cent over the 1955 figure. Fuel oil deliveries, chiefly for central heating and steam raising, showed an increase of nearly 16 per cent compared with the previous year. Gas/diesel oil consumption increased by 10·5 per cent. Motor spirit, at 6,323,654 tons, represents only a 1·3 per cent increase over 1955, and it is interesting to note that in the last quarter restrictions only accounted for a 1·2 per cent fall. The demand for burning oil increased by 20 per cent. All other petroleum products showed increases, with the exception of vaporizing oil which, at 574,175 tons, represented a fall of 16·7 per cent. Motor spirit produced by low-temperature carbonization amounted to 3,633 tons, which is a slight increase over the 1955 figure; motor and aviation spirit produced by hydrogenation, at 84,114 tons, represents a fall by comparison. Refined benzole, at 314,489 tons, is a substantial rise on the 1955 total.

Trade Fairs and Exhibitions

A Broadsheet on "Trade Fairs and Exhibitions" (No. 411. Pp. 109–140. 3*s*. 6*d*. net), issued by Political and Economic Planning, is concerned with British sales and prestige abroad. After considering briefly in succession international exhibitions (especially the forthcoming Brussels Exhibition, April to October 1958, the total cost of which to Britain is expected to be £1–2 million, including up to £400,000 from the Exchequer), trade fairs and international trade fairs, the broadsheet discusses the problem of selling British goods overseas, before considering, finally, what future British policy should be. The great disadvantage of general fairs for highly industrialized countries is that the range of products is now so great that no general fair, however large, can show them all. There is a strong case for greater international emphasis in British trade fairs, whether general or specialized. Britain at present is without an up-to-date exhibition centre offering amenities comparable with those available in many European countries. Consideration is now being given to the possibility of the British Industries Fair at Castle Bromwich becoming the first British general international trade fair. However, Political and Economic Planning argues strongly that the London area is in many ways more suitable, and suggests that the Crystal Palace, Olympia and Earls Court sites should be fully considered. It is important that early decisions should be reached on the part which international trade fairs should play in Britain in the future, and the broadsheet suggests also that there is a case for an executive body, representative of both Government and industry, to finance and deal with the difficult question of British pavilions at trade fairs which are organized on the national pavilion pattern.

International Council of Scientific Unions

FOR all that it represents, the 1957 Year Book of the International Council of Scientific Unions (pp. ii+72. London: International Council of Scientific Unions, 1957) is among the most modest of annual reports. The calendar of meetings for 1957 arranged by the thirteen international scientific unions which make up the International Council alone makes fascinating reading; the truly international nature of the organization is shown by the list of countries belonging to the different scientific unions. Forty-two countries, including the U.S.S.R. and Rumania, belong to the International Council; even more encouraging is the fact that forty-seven countries, including the People's Republic of China and Hungary, belong to the International Union of Geodesy and Geophysics. The Yearbook also contains a list of all members of commissions and important committees of the different organizations, the text of the agreement between the International Council of Scientific Unions and Unesco and reports on activities during 1955–56.

Conference on Ethology and Comparative Psychology

BETWEEN July 9 and August 3, a conference was held at the Center for Advanced Study in the Behavioral Sciences, Stanford, California, the purpose of which was to facilitate the exchange of ideas between representatives of ethology and comparative psychology. No formal programme or agenda was drawn up in advance of the meeting and no 'papers' in the usual sense were presented. Each participant reported results of his more recent investigations. This took approximately two weeks; the second half of the conference was given over to the discussion of general theoretical issues such as the use of formal and physiological genetics in the interpretation of behaviour, the ontogeny of behaviour, the role of physiology in behavioural theory, phylogenetic differences in motivational systems, 'drive' as a hypothetical concept and as an intervening variable, and a number of specialized ethological concepts including those of displacement activities, innate releasing mechanisms and imprinting. Because the conference was planned as an informal, relatively unstructured series of meetings, and because each participant was promised that he would not be required to produce any publishable paper, the results of the conference will not appear in print. However, intangible results were numerous and important, and each contributor felt that his own thinking and research would benefit greatly as a consequence of the discussions. The expenses of the conference were defrayed by the Center. Those taking part were: Gerard Baerends (University of Groningen), Frank Beach (Yale University), Harry Harlow (University of Wisconsin), Donald Hebb (McGill University), Eckard Hess (University of Chicago), Robert Hinde (University of Cambridge), Jan van Iersel (University of Leyden), Daniel Lehrman (Rutgers University), Jay Rosenblatt (American Museum of Natural History), Niko Tinbergen (University of Oxford) and David Vowles (University of Reading).

Fungal Saccharification of Potato Mashes

SEMI-PILOT plant experiments on the saccharification of potato mashes by means of fungal preparations are described by K. Beran, M. Burger and S. Zelenka in *Folia Biologica* (3, 89; 1957), the journal of the Academia Scientiarum Bohemoslovenica. The saccharification was effected by using a combination of preparations of *Aspergillus niger* and *A. oryzae* and of *A. niger* alone. No special technological difficulties were met, and it was not necessary to add malt to the mash. The mashes saccharified by the fungal preparations were more fluid than those saccharified with malt. Liquefaction was normal when *A. niger* alone was used. The yield of alcohol from mashes saccharified with the fungal preparations was greater than from mashes saccharified with malt and was increased still further by using a suitable strain of yeast. When using a preparation of *A. niger*, the higher saccharification temperature (65° C.) and the lower *p*H (4·5–5·0) prevented the development of infection, both during saccharification and also, as regards the *p*H, during fermentation. The quality of the crude alcohol obtained was the same, whether fungus or malt was used. As a result of the saccharification activity of preparations of *A. oryzae*, galactose was released during fermentation.

Visual Deficiency Symptoms in Rubber

E. W. BOLLE-JONES has made a useful contribution to our knowledge of the visual symptoms in *Hevea brasiliensis* of deficiencies in macro- and micro-nutrients (*J. Rubber Res. Inst. Malaya*, 14, 493; 1956). These symptoms, which are briefly described in the text and are excellently illustrated in colour and by photographs, were obtained in seedlings grown in pot sand culture. Many of the deficiencies described, for example, those of copper, have not been encountered in the field, but others, for example, of magnesium, are of common occurrence. As the author implies, the whole question of deficiency symptoms is one that needs to be approached with some caution; but work of the kind now under consideration has done much to clarify the situation. Thus, whereas the symptoms of magnesium deficiency are so diagnostic as not to need confirmation by chemical analysis, those due to shortage of calcium are ill-defined and call for supporting analytical evidence. The materials used were seedlings of clone *Tjir* 1 or clone *PB* 86. Deficiency symptoms now illustrated and described, but not previously published, include those of calcium, boron, copper, zinc and, in part, sulphur.

Molybdenum Nutrition and Free Amino-Acids in Tomato

J. V. POSSINGHAM has obtained some interesting results in an investigation of the effect of molybdenum on the content of free amino-acids and amides in tomato plants (*Austral. J. Biol. Sci.*, 10, 40; 1957). The plants, which had been cultured in the absence of molybdenum, were provided with molybdate, and the consequent changes in the relative amounts of the free amino-acids and amides were followed over an experimental period of four days. Quantitative paper chromatography was used for estimating the individual free amino-acids and amides, the results being expressed on a dry-weight basis. Changes in the concentrations of many of the individual amino-acids occurred within four hours of applying molybdenum. Large increases in the concentration of aspartic acid, glutamic acid, glycine, glutamine and asparagine occurred initially with molybdenum treatment, but were followed by steady declines. A different pattern of change was shown by the two compounds β-alanine and γ-amino-butyric acid, both of which decreased in concentration soon after molybdenum was applied. The results of this investigation are discussed in relation to the pathway by which the products of nitrate reduction are incorporated into proteins.

Mathematical Colloquium at University College, Cork

ABOUT thirty delegates from Irish universities, the Dublin Institute for Advanced Studies and the Irish Civil Service attended a mathematical colloquium at University College, Cork, during July 10–12. Profs. M. H. A. Newman and G. Temple gave short courses of lectures on mathematical logic and the theory of distributions, and splinter groups in algebra, analysis and applied mathematics were also organized. It is hoped to arrange an Irish mathematical colloquium at regular intervals in future. Inquiries should be addressed to the Organizing Secretary, Cork Mathematical Colloquium, Department of Mathematical Physics, University College, Cork.

Forestry and the United Nations

AN interesting and informative article on the forest work of the Food and Agriculture Organization of the United Nations by Sir H. Beresford Peirce appears in *Forestry* (30, No. 1; 1957. Oxford University Press). Forestry is one side only of the work of the Food and Agriculture Organization, which has five divisions—agriculture, economics, nutrition, forestry and fisheries. The forestry work is of a world-wide order, so as to reach backward countries where the aims and objects of scientific forestry are unknown or neglected. The Organization keeps in touch with the needs and wishes of governments all over the world through a number of regional Commissions, including the European Forestry Commission based on Rome, the Near East Commission based on Cairo, the Latin American Commission based on Rio de Janeiro and the Asian Pacific Forestry Commission based on Bangkok. Because of its special problems there is also a sub-Commission for the Mediterranean area. There is no commission as yet for North America, nor for West Africa south of the Sahara, although the latter is a region where there is much to be done in the forestry line.

A World Forest Inventory, which has been one of the objects of the forestry work of the United Nations, was first completed in 1948; the second, an appreciably better assessment, appeared in 1953; and a third is planned for 1958.

Announcements

DR. RICHARD E. SHOPE, of the Rockefeller Institute, has been awarded the George M. Kober Medal of the Association of American Physicians for his work on the occurrence of animal viruses.

PROF. W. E. MORTON, professor of textile technology in the University of Manchester, has been awarded the Warner Memorial Medal for 1957 of the Textile Institute. The Warner Medal is awarded in recognition of outstanding work in textile science and technology, the results of which have been published, and particularly for work published in the *Journal of the Textile Institute*.

PROF. R. CRUICKSHANK, principal of the Wright–Fleming Institute of Microbiology, St. Mary's Hospital Medical School, London, has been appointed professor of bacteriology in the University of Edinburgh.

A GENERAL meeting of the Association of Applied Biologists will be held in the University of Leeds during September 19–20. Particulars can be obtained from Dr. J. H. Western, Department of Agriculture, The University, Leeds 2.

THE next meeting of the Photoelectric Spectrometry Group will be the ninth annual general meeting and will take the form of a joint meeting with the Photobiology Group to be held in the Old Medical School, University of Liverpool, on September 26. The subject of the meeting will be "The Spectroscopy of the Natural Pigments". The Photobiology Group will also meet on the following day. Details can be obtained from the Honorary Secretary, Photoelectric Spectrometry Group, 56 Arbury Road, Cambridge, or from the Honorary Secretary, Photobiology Group, Chester Beatty Research Institute, Royal Cancer Hospital, Fulham Road, London, S.W.3.

A CONFERENCE on the Rheology of Disperse Systems, organized by the British Society of Rheology, will be held in the Natural Sciences Building of the University College of Swansea, Singleton Park, Swansea, during September 19–21. Accommodation has been arranged at the University hall of residence. Further details can be obtained from the Hon. Secretary of the British Society of Rheology, Mr. N. Wookey, 52 Tavistock Road, Edgware, Middlesex.

A CONFERENCE on "Operational Research" has been organized by the Operational Research Society (United Kingdom), the Operations Research Society of America and the Institute of Management Sciences (New York), and will be held in Oxford during September 2–6. About 250 delegates from twenty countries are expected, and reprints of the papers to be presented have been prepared. The Conference Secretary is Miss B. Kornitzer, 6 Gray's Inn Square, London, W.C.1.

ERRATUM. In the communication entitled "The Free Energy of Hydrolysis of Adenosine Triphosphoric Acid" in *Nature* of June 29, p. 1350, the factor 10^3 was omitted from col. 8 of the table. The equilibrium constants for the hexokinase reaction should read $1 \cdot 380 \times 10^3$ and similarly down that column.

NEW RESEARCH HEADQUARTERS OF THOMAS HEDLEY AND CO., LTD.

By Dr. E. R. WILSON

THE new Research Headquarters of Thomas Hedley and Co., Ltd., at Longbenton, Newcastle upon Tyne, officially opened by the Duke of Northumberland on June 14, is the result of the post-war expansion of the Company's Research Division. Only eight years ago, in 1949, modern laboratories were completed alongside Hedley's factory in City Road, Newcastle. Since that time the Research Division has grown rapidly, and with the formation of a new Basic Research Department in 1954 it became evident that much larger laboratories would soon be required. The 45-acre site at Longbenton was chosen because it had the advantages of being out of the City and yet still accessible to public transportation and utilities, and it provided ample room for future expansion. The new Research Headquarters at present occupies eight acres of this area (Fig. 1).

The new building houses the departments concerned with product research and development of both washing products and edible products. Hedley makes a sharp distinction between basic research and applied research, and (by the Company's definition) the nature of the work carried out in the new laboratories is applied research. The basic research for the Company continues to be carried out at the City Road laboratories, where the Basic Research Department has expanded into the space vacated by the applied research groups as they moved to Longbenton.

Although the Company defines the research at Longbenton as 'applied', much of it is the type of research that is commonly termed 'basic', since the work normally begins at the test-tube stage. From here it proceeds by definite steps from small-scale, glass-ware, laboratory bench reactions, in which new compounds are synthesized and evaluated for new properties, to small batch-process pilot plant equipment, and finally to small-scale continuous-process pilot plant equipment which duplicates all conditions expected in factory production.

The building is designed in two main blocks on an east–west axis with a connecting north–south block. With the exception of the rear east–west block, which houses the pilot plant area, the building is single story. It is anticipated that the remainder of the Research Division now at City Road will eventually join the group at Longbenton, and allowance has been made in the design for future expansion.

The front block is arranged so as to have executive and administrative offices on one side of the corridor with laboratories on the other side. In these laboratories, graduate chemists and their technical assistants carry out the product research work for the Company. Their purpose is to formulate all of the Company's products so that each in its field will be entirely acceptable to the consumer for performance and appeal. That this can be an extremely complex operation is illustrated by the fact that a synthetic detergent granule, for example, normally contains as many as twenty different chemical compounds which must be present in the correct proportion for optimum performance.

In order to make certain that formulations do represent improvements which are not only detect-

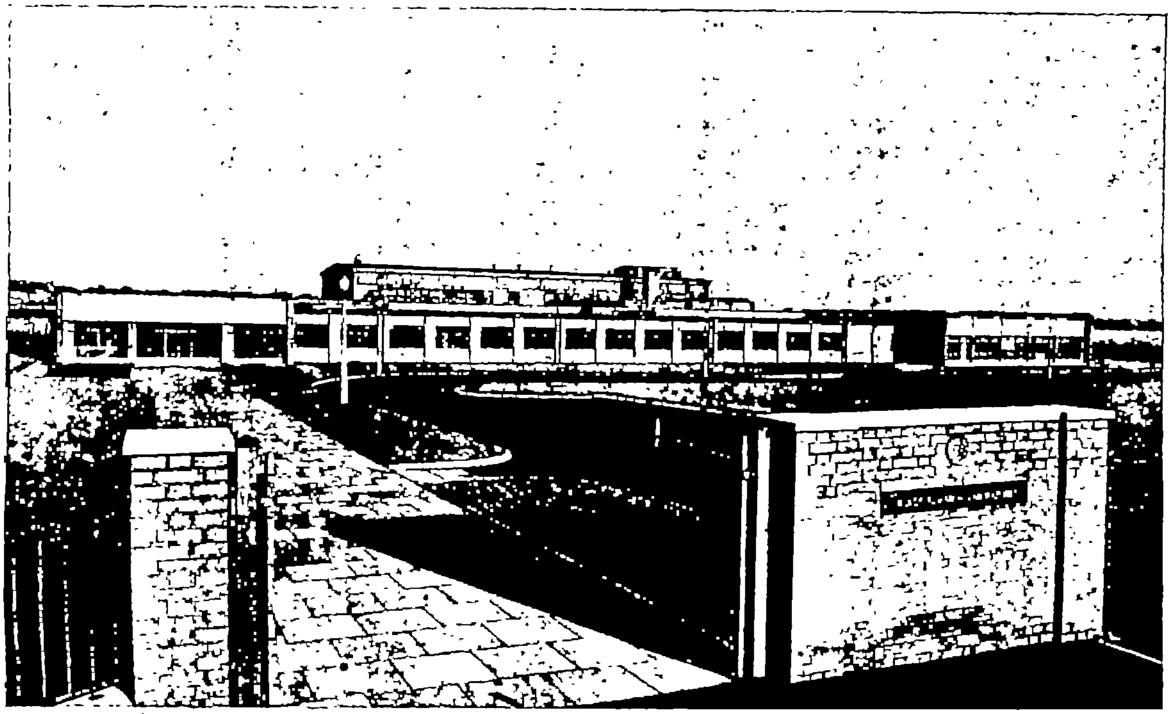

Fig. 1

able by sensitive laboratory tests but also easily seen by the final, less exact consumer, the laboratories include a research laundry and a research bakery. In the research laundry facilities have been installed which enable the scientist to set up every conceivable condition to duplicate domestic washing procedures for experimental purposes as well as to study all types of innovation, such as new washing machines, as they appear on the market. The same idea is behind the range of equipment in the research bakery, where all the problems confronting the baker can be duplicated and studied, and new shortening formulæ and recipes for the bakery trade formulated.

The back, east–west block houses the pilot plant area and the development laboratories. Approximately one-third of this two-story area is clear from floor to roof so as to accommodate the larger pilot-plant equipment. Smaller pilot-plant equipment is located under the mezzanine floor which covers the remaining two-thirds of the building. The mezzanine floor itself has offices and laboratories on both sides of a central area which is equipped with benches, fume hoods and smaller pieces of development equipment.

In these laboratories problems vary considerably in magnitude. For example, the chemist may be synthesizing previously unknown compounds to test as detergents. Simultaneously, he may be developing a new chemical process for manufacturing a detergent on a commercial scale, or developing a new formula to meet certain desired performance characteristics. He is, in effect, responsible for both the generation of ideas leading to new products and for the development of those ideas from the laboratory bench through the pilot plant to the factory.

In order to carry out such a programme, facilities include an area under the mezzanine floor for an engineering division development group as well as various service shops. This combination permits on-the-job construction of all new pilot plant and processing equipment. The north–south connecting block between the two east–west blocks contains various constant-temperature rooms, as well as additional product research laboratories. The building also contains, in the front east–west block, a technical library which is an extension of the main library in the Basic Research Department in the City Road laboratories. Also provided are a hospital suite and a large, pleasant dining room together with a modern kitchen.

Approximately 230 of the Research Division's staff of 300 are at work in the new building, which cost more than £500,000 to build and equip. At the present time, on the production side of Hedley's business, one person out of every five is engaged in some form of research.

HATFIELD TECHNICAL COLLEGE

By Dr. W. A. J. CHAPMAN

Principal

HATFIELD Technical College has just completed the first five years of its existence. The College is a unit in the plan for Hertfordshire which includes senior colleges at Letchworth, Hatfield and Watford, associated with a chain of colleges of further education. When the plan is complete, Hatfield will have close ties with colleges at St. Albans (4 miles), Welwyn Garden City (3 miles), Hertford (8 miles) and Barnet (8 miles), to offer a comprehensive service for the central portion of the county.

The College was conceived in 1947 to be on a ninety-acre site to the south of Hatfield presented to Hertfordshire County Council by Mr. A. S. Butler, at that time chairman of the de Havilland Company, Ltd. An interesting feature of the preliminary planning was the almost complete absence of any organized service of further education in the area upon which estimates of accommodation could be based. For many years previously the de Havilland Technical School at Astwick Manor had been providing the academic facilities for the Company's apprentices, and latterly the County Council participated in its work. The remainder of the population in the area sought their educational facilities in London, to which transport facilities are good.

The work on the building started late in 1948 and it was opened for classes in 1952 as the first completely new college erected after the War. The building is of modern design with the accommodation on a single floor except at the front where, due to a sloping site, the upper floor is on the level of the rest of the building. The construction is of a framed semi-prefabricated character with a reinforced concrete frame and brick in-filling. This form of construction was dictated by the shortage of steel prevalent at that time, and the bulk of the concrete frame members were manufactured at a plant set up a few miles from the site. The accommodation originally planned included facilities for engineering, science, building, commerce and social and professional studies; but about 1950, during the course of erection, the wing containing the science laboratories was subjected to an economy measure and became deferred. This necessitated some temporary improvization by the conversion of low-level accommodation and delayed the start of science work until January 1953.

When classes commenced, except for small numbers of A.F.R.Ae.S. students, the most senior work in operation was for the third year of the Ordinary National Certificate in engineering by a feed from the de Havilland Technical School which, by an arrangement with the Ministry of Education, was conducting S.2 classes. Engineering was conducted in the two departments of works and production and technical and design, with emphasis on manufacture and design, respectively. The electrical work was shared between these departments according to its practical or professional bias. From the beginning, all first-year work in engineering was conducted at the colleges of further education as the first stage of the Authority's plan to remove progressively all work up to intermediate standard. Work in all faculties other than engineering commenced at the first year of studies with a year's delay in any serious work in science.

The growth of the demand on the College and its expansion in numbers and staff have been considerable. The support was probably stimulated by the development of the new towns at Hatfield and Welwyn Garden City, and the increases in population taking place in other parts of Hertfordshire, but no doubt the main impetus was the spirited interest shown by industry.

The County Council realized that the enlightened governance of the College would be achieved only by the inclusion of a large proportion of governors representing industry, commerce and the universities, while the representatives of the County Council themselves were men and women with wide experience of the sort of problems with which the new College was likely to be faced.

In addition to the guidance given over the years by the Governing Body itself, each department set up an advisory committee consisting of representatives of the industry concerned with particular technologies. The influence of these committees has been immeasurable. Busy executives have given up their leisure time without stint, and the confidence they have shown through this work has been an inspiration to the staff of the College.

Experience in an entirely new building, devoid of any tradition and in an area lacking anything in the way of precedent, has necessitated a few adjustments during the course of development. The initial plan of the head of a department, acting as academic registrar, proved to be impracticable and the commerce and social studies were merged into one, releasing the head of the former to take the post of academic registrar. The rapid growth of electrical engineering necessitated the formation of a separate department and some internal adaptations to provide more laboratory accommodation. The formation of a science department was delayed some twelve months from the start owing to delays in providing temporary accommodation.

A new building, especially if planned on unusual lines, excites comment, and this one was no exception. Visitors have come from all parts of the world, in some instances to make a very close study of the design and layout. Those who have been in the College during these past five years have appreciated the thought that went into its design and, now that the surroundings are mellowing, its charm and suitability for its function. In some respects, it was soon found to be too small to do all that was needed, but it has lent itself readily to minor adaptations to meet the changing demands of industry. The completion in the next two years of a new block which includes mainly laboratories, classrooms and more library accommodation will give that extra space which at present is lacking.

At the end of five years the College is now established on a firm basis with a full programme of Higher National Certificate and Diploma work in engineering, building, management and chemistry and final City and Guilds courses in various subjects. The College has a part-time degree course in aeronautical and electrical engineering and sandwich courses are being developed with a view to a future application for the Hives award. The recent visiting party from the Royal Institute of Chemistry is to recommend approval of courses for Parts I and II of the A.R.I.C. examination. The arrangements being made by the Governors and the Authority, for a number of neighbouring colleges of further education, will result in all work of intermediate standard being taken out of the College within a few years. By its character and setting, together with the tradition it has already attained, the College is well set for the responsibilities that this stage will involve.

MODERN ANALYTICAL CHEMISTRY IN INDUSTRY

WITH the increasing interest in scientific symposia and congresses one sometimes wonders wherein lies their attraction. Is it the attractiveness of the venue, the brilliance of the speakers, the interesting or topical nature of the subject-matter or is it a mere thirst for knowledge? Certainly the Congress on "Modern Analytical Chemistry in Industry", organized by the Scottish Section of the Society for Analytical Chemistry and held in the University of St. Andrews during June 24–28, had all these qualities and was an outstanding success. Three hundred delegates attended, and many more applications had to be refused. The Congress was remarkably well organized, and the organizing committee, consisting of Dr. Magnus Pyke (chairman), Mr. J. A. Eggleston (secretary), Mr. J. Brooks, Mr. H. C. Moir and Mr. A. F. Williams, had not only planned well but continued to give themselves unsparingly to ensuring the smooth running of the Congress and the comfort of the delegates.

The lectures were divided into three sections, dealing respectively with analyses in modern industry, the application of some newer analytical techniques in industry, and developments in analysis for new problems in industry. Each section was prefaced by a special lecture, the lecturers being Dr. J. Craik, chairman of the Nobel Division, Imperial Chemical Industries, Dr. E. B. Hughes, chief chemist of J. Lyons and Co., Ltd., and Prof. G. F. Smith, University of Illinois. Altogether, there were twenty-three lectures spread over eight sessions, each session being presided over by one of the following well-known personalities in chemistry: Prof. E. L. Hirst, Dr. H. W. Melville, Dr. D. Trail, Dr. R. Belcher, Prof. D. H. R. Barton, Dr. C. L. Wilson, Dr. D. W. Kent Jones and Dr. Magnus Pyke.

The Congress was opened by Dr. Magnus Pyke, who referred to the changes taking place in analytical chemistry. There was a basic change, the uncovering of the knowledge of the physical world and particularly the unfolding of the nature of atomic structure, bringing a simplicity to the understanding of the diverse elements. A second change was the increasing use of physical instruments to measure the progress of chemical reactions. While these needed to be supervised by an analyst understanding the operating principles of the instruments and the chemistry of the reactions which they interpreted or measured, their manipulation could be entrusted to a young girl. A third change came from changes in the chemical industry with its trend towards continuous operations and automatic control.

Dr. J. Craik then opened the first group of lectures with his introductory lecture on "Analytical Chemistry in Industry". He stressed the help given to analysis by new techniques and by the development of instrumentation, help in overcoming limitations of man-power and in enabling problems to be solved which could not have been undertaken by the older classical methods. For example, the analysis of glycerol had been greatly simplified and speeded up by adopting the sodium metaperiodate method. Even simple volumetric procedures such as the determination of sulphuric acid, nitric acid and nitro compounds could be improved by the use of automatic titrimeters. The use of some of the newer techniques had also stimulated research into the behaviour of existing instruments; for example, the use of gas chromatography had greatly increased our knowledge of the behaviour of katharometers. Dr. Craik considered that any large industrial organization needed an analytical research group, for problems were continually arising having no standard solutions and for which new techniques might be needed.

Following this lecture, Dr. G. R. Davies (Chemical Research Laboratory) dealt with some of the analytical research carried out by various stations of the Department of Scientific and Industrial Research. Particular attention was directed to the work of the Building Research Station in applying differential thermal analysis to the study of building materials, to the development of automatic methods of determining dissolved oxygen by the Water Pollution Research Laboratory and to the studies of the Chemical Research Laboratory on inorganic chromatography.

Analytical methods in the iron and steel industry formed the content of the next two papers. In the first of these, Mr. B. Bagshawe (Brown–Firth Research Laboratories) directed attention to some of the many changes which had taken place in recent years. Specifications were more exacting, more elements were being determined and a much larger use was being made of organic reagents and of absorptiometric methods. Co-operative research within the industry had led to the development of British Standard methods. Mr. Bagshawe then gave some examples of the methods employed.

Spectrographic methods of steel analysis were discussed by Mr. D. Manterfield (Steel, Peech and Tozer, Ltd.). The large tonnages of steel now being produced called for rapid methods of analyses, and by spectrographic methods steel of all types, slags and some refractories could be rapidly analysed. Mr. Manterfield then dealt with photographic and direct-reading instruments, illustrating the latter by means of the quantometer.

Mr. R. C. Chirnside (General Electric Co., Ltd.), in discussing the contribution of analysis as a research service to chemical problems in the electrical industry, directed attention to the wide variety of materials in which the electrical industry had an interest. Glass, ceramics, certain metals and alloys represented major interests, but fluorescent materials, thermionic coatings, semi-conductors, etc., had been developed and were manufactured. Much of the analysis carried out by industry was meaningless, Mr. Chirnside said, and still consisted in a catalogue of acidic and basic oxides. The analyst should have a greater interest in his answers and in interpreting his results to others. The failure of the conventional presentation of results to represent a composition was demonstrated by reference to an ore containing copper and zinc sulphides which could not be separated by flotation because they were present, not as a mixture of sulphides, but as a complex as shown by X-ray diffraction. Further examples of the uses of many techniques in dealing with analytical problems were given.

Physical methods of analysis used by the gas industry were described by Mr. A. B. Densham and Mr. G. Gough (North Thames Gas Board). Mr. Gough dealt with absorption, emission and fluorescent spectroscopy and gave examples of their use. Mr. Densham then discussed the use of chromatography, radioactive tracers, polarography, X-ray diffraction and differential thermal analysis.

Dr. G. M. Bennett (Government Chemist) gave an interesting review of the activities of his department. In addition to the immense volume of revenue work, advice and service were provided for other Government departments. Dr. Bennett then dealt with some of the problems encountered in the revenue work, where the methods of assessing duty on alcohol, tobacco and sugar were all laid down by law. Topics dealt with by the non-revenue divisions were illustrated by the development of methods for determining toxic gases in factory atmospheres, the analysis of flours, nutritional surveys and the identification of the cause of the outbreak of food poisoning at Pontardawe in South Wales.

The final paper in this first section was by Dr. D. C. Garratt (Boots Pure Drug Co., Ltd.), who dealt with analytical developments in a pharmaceutical laboratory. He instanced the analysis of metals by compleximetric titrations, by emission spectroscopy and by flame photometry. Paper chromatography was used for assessing the activity of freshly prepared samples of insulin, insulin solutions and insulin zinc suspensions. Alkaloids were separated quantitatively on columns of oxidized cellulose.

The second group of lectures, on the application of some newer analytical techniques in industry, was introduced by Dr. E. B. Hughes's lecture on "Analysis and Food". Before beginning the lecture he read a tribute to the late Dr. L. H. Lampitt, who had originally been asked to deliver this lecture. Dr. Hughes began by saying that analysis was the backbone of the food industry. There were chemical safeguards for the buying, processing, cooking and packaging of food products. The care required to prevent any variation in the products was illustrated by the close control exercised during the manufacture of the large volume of ice cream and the miles of Swiss roll produced daily. Dr. Hughes then referred to the importance of controlled humidity in micro-ecological work, to the separation of the constituents of tea extracts by paper chromatography and to the use of X-ray diffraction in routine analysis and research.

In the next lecture Dr. R. L. M. Synge (Rowett Research Institute) discussed the application of some of the physico-chemical methods, which had proved useful for the analytical separation of smaller molecules, to substances of high molecular weight. Counter-current distribution and chromatography based on liquid–liquid partition were considered as well as ion exchangers and solid adsorbents, including molecular sieve effects. A number of electrophoretic methods were described as well as procedures depending on differences in diffusion behaviour or on selective permeability in membranes.

"Emission Spectroscopy in Industrial Analysis" was the title of the paper by Mr. M. Milbourn (Metals Division, Imperial Chemical Industries). Various aspects of this technique were dealt with, including the scope of the method and the directions in which future progress is needed.

Dr. A. T. James (Medical Research Council), speaking on "Analyses in Medical Research", pointed out that there were few analysts in medical research. Each research worker carried out his own analytical work, for this varied with each problem. The general conduct of such a research was outlined and illustrated from the work on hypertensin, on the antagonist of dihydrostreptomycin and on the fatty acids derived from animal sources.

Infra-red spectroscopy was dealt with by Dr. A. E. Martin (Grubb, Parsons and Co., Ltd.), who described the modern equipment available, including the less expensive instruments of restricted range which were very suitable for analytical use, and also instruments for process control. The various techniques available and a number of interesting analytical determinations were outlined.

An interesting account of the application of modern methods to the analytical problems of the plastics industry was given by Dr. J. Haslam (Plastics Division, Imperial Chemical Industries). Reference was made to chromatographic studies of hydrolysates from nylon and related products, to the examination of complex plasticizers in polyvinyl chloride and to the depolymerization of 'Perspex' and examination of the monomers by gas chromatography.

In his paper on "Modern Analytical Chemistry and the Rarer Metals", Mr. A. R. Powell (Johnson, Matthey and Co., Ltd.) showed how the increasing industrial use of these metals had called for rapid methods of analysis. Lithium, rubidium and cæsium were conveniently determined by flame photometer, while spectrophotometry was useful in estimating the rare earths or the platinum metals. For that very important field of analysis, the determination of trace impurities in pure metals, the examples chosen were platinum in palladium and arsenic in germanium. The determination of non-metallic impurities in pure metals was also mentioned.

"Analytical Research in the Nobel Division of I.C.I." was the title of Mr. A. F. Williams's paper, and he showed that some of the problems encountered could only have been solved by modern methods. Chromatography had been used to separate glycerol from sugars, diphenylamine from its nitro derivatives and to separate 2 : 4- and 4 : 6-dinitroresorcinols from the mononitro compound, followed in the last case by polarographic determination. Analysis of mixtures of methyl chlorosilanes by vapour phase chromatography was also described.

A thought-provoking paper by Dr. B. W. Bradford (Billingham Division, Imperial Chemical Industries) on "Process Analytical Control" brought this second session to a close. Dr. Bradford dealt with the implications of the analytical service on the working process, the cost of analytical control, the difficulties of getting junior staff for routine analysis and the consequent development of instrumentation. The final objective was the linking of continuous analytical control on the plant to the actual process. Dr. Bradford then dealt with developments at Billingham in automatic analytical instruments ; where possible, physical methods were used, while in other cases analytical procedures were mechanized. Examples were given of the use for control analysis of automatic titrimeters, optical, mass and X-ray spectrometers and gas chromatography.

The third group of lectures was opened by Prof. G. F. Smith (University of Illinois), whose topic was "New Analytical Reagents in Industrial Plant Control Operations". He pointed out that in spite of the emphasis on instrumental methods of analysis, wet chemical methods were still highly important. Recent years had seen an enormous development in organic analytical reagents, and reference was made to some of these and particularly to complexones and ion-exchange resins. Many organic reagents were of a non-specific character, but specificity could often be increased by structural modification. Progress on these lines was slow because the analyst depended on the organic chemist to do this for him instead of doing it himself. Prof. Smith then gave examples of the use of periodates, ceric salts and perchloric acid in analysis and said that these reagents deserved a wider use.

In the absence of Mr. A. Smales through illness, the next paper, on the use of radioactive and stable isotopes in industrial and analytical problems, was given by Dr. D. J. Ferrett (Harwell). He first outlined those properties of the nucleus which could be used for analytical purposes, including spin and mass, and followed with a consideration of equipment and of health hazards in dealing with tracers. The interaction of a stable nucleus with radiation could lead to attenuation, radioactivity or secondary emission, and analytical procedures depending on these were discussed. Vacuum spark and isotope dilution methods of mass spectrometry were considered, while brief reference was made to nuclear magnetic resonance.

Mr. D. A. Patient (Baird and Tatlock (London), Ltd.) then described the 'B.T.L. Analmatic' range of automatic instruments. Three categories were dealt with : (1) semi-automatic equipment needing an operator to prepare samples and work out the results ; (2) equipment to cater for techniques involving the handling of a large number of discrete samples ; and (3) fully automatic laboratories.

Polarography was covered by three experts in this field from the U.K. Atomic Energy Authority (Dr. G. C. Barker, Mr. G. W. C. Milner and Mr. H. I. Shalgosky). Mr. Milner briefly compared the various types of polarograph and then described a wide range of analytical applications of the square-wave model. Mr. Shalgosky then dealt with the cathode-ray instrument, which was rapid and easy to operate and was well suited for routine analysis. Dr. Barker finally discussed the limitations of the square-wave polarograph and the methods being adopted to increase its sensitivity.

Gas chromatography was mentioned in many lectures, but it was left to Dr. A. I. M. Keulemans (Koninlijke Shell Laboratory, Amsterdam) to deal more fully with the subject, particularly in its application to the petroleum industry. Describing chromatography as the greatest single advance in analytical methods since the discovery of emission spectroscopy, he said that its techniques had soon been used by the petroleum industry. The value of gas chromatography was illustrated by its successful application to two problems : (*a*) the determination of impurities in *cyclo*pentadiene ; and (*b*) the explanation of the presence of acetone in doubly distilled methyl *iso*butyl ketone.

In the last paper of the Congress, Prof. C. F. Davidson (St. Andrews) dealt with the geochemical approach to prospecting. In prospecting for mineral deposits, the economic geologist had increasingly to direct his attention to sub-surface ore bodies hidden beneath tropical soils, forests, bogs and other covering. In this search he was becoming more dependent on geochemical aids. Sometimes a metal might be found by the company it kept or by mass spectrographic studies of absolute age. In other cases, analyses of soils, groundwaters, streams or vegetation might point to geochemical anomalies reflecting the presence of a nearby ore-body.

Looking back on the Congress, one could not help being impressed by the keenness and enthusiasm of those who attended. Session after session, the lecture hall was crowded with eager listeners ; discussions inside and outside the hall were on a high level and few who attended could have failed to gain much knowledge which should prove valuable in later days.

G. R. DAVIES

ELECTRONICS IN AUTOMATION

"ELECTRONICS IN AUTOMATION" was the title given to the British Institution of Radio Engineers' Convention held in Cambridge during June 27–30. The philological challenge invited by the word 'automation' should first be answered. It may be classed as an item of that vigorous technical slang which profitably accompanies the advance of the specialized arts. Such words may start as an adaptation or corruption of some accepted dictionary word but eventually acquire a specialized significance. The present word denotes the replacement of human operations by automatic systems in industrial and scientific processes. This tendency is not new, but the remarkable increase in its tempo, which has recently been evidenced largely as a result of the introduction of electronic devices or concepts, may be interpreted as the beginning of a second industrial revolution.

The economic and social implications of this situation were discussed by the president, G. A. Marriott, in his opening address. His conclusions may be summarized in his remark that "The only serious threat to the British economy and standard of living would be failure to take advantage of every possible aid from automation".

The papers were supplemented by an important though limited exhibition of apparatus, a valuable selection of films bearing on automation and a range of visits.

The papers were grouped into six sessions under the following headings: (1) Office machinery and information processing, (2) machine tool control, (3) chemical and other processes, (4) automatic measurement and inspection, (5) simulators, (6) automation in the electronics industry.

In the first session the papers emphasized the importance of the ferro-magnetic store, which seems likely to take over the memory function in computors to an overriding extent. Another logical operation which created great interest was concerned with the automatic reading of typed or printed characters.

Session 2 presented convincing details as to the increasing importance of automation in the control of machine tools; for example, the operation of a jig borer from punched card or other digitally stored data. A problem associated with these operations is the accurate measurement of table movements. A new and interesting solution to this, the 'Inductosyn', was the subject of a separate paper. The construction of the 'Inductosyn' is relevant to Session 6, since the device amounts to a 'resolver' with accurately printed windings.

The papers presented in Session 3 were arranged in two groups, the first dealing with the problems of instrumentation for the control of process streams in atomic energy projects and the uses of radioactive techniques in process control, while the second dealt with the process control of chemical plants from a more general point of view. Automatic sampling methods are essential in atomic energy plants and involve the engineering of laboratory methods which were described in one paper, while two papers showed how the measurement of absorption of radiation provides methods of monitoring the density of fluids in pipes from outside or for controlling the level in vessels. In the field of general process control, the possibilities of programming the controller by means of punched cards or by a computer were discussed in some detail.

Session 4 emphasized that basically an automation system must depend on the inspection of its final product and a paper in this session was devoted to the special advantages of various devices. Other papers described the control of steel strip manufacture, and automatic ultrasonic and X-ray inspection techniques. The ultrasonic system employs scanning to speed up the inspection of castings, plates, etc., while image intensification of the fluoroscopic picture is used in many industrial processes.

A more apt title for Session 5 could perhaps have been "Simulators and Analogue Computors". Under the first heading three of the four papers were devoted to training devices, namely, radar simulators for military purposes, and a training simulator for nuclear power plant operations. The degree of realism introduced in these devices was notably high. The analogue computor group embraced applications to the design of aero-engine controls, and the study of elastic beams. A general paper presented the case for analogue versus digital computing in certain cases. These two devices are complementary and in some cases digital methods may be incorporated in analogue machines. This involves an analogue/digital converter, the subject of a separate paper.

The emphasis of Session 6 was on printed circuits and associated manufacturing methods. The important subjects of automatic valve production and automatic component production were excluded by security considerations. One paper gave the most complete disclosure to date of the giant Cossor printed wiring installation. There seems no possible doubt that printed wiring plus a limited degree of printed component technique will take over almost completely from previous methods. Most printed wiring manufacture involves a liquid etching process. One manufacturer, concerned with long-life telephone apparatus, prefers to avoid a possible corrosion hazard by relying on mechanical engraving. Although the printed-wiring board by itself constitutes a major advance, it is possible also to render the assembly and soldering processes fully automatic. Advanced technique was shown, but it must be recognized that, assembly costs being small in relation to component costs, major economies can be found only by reducing the latter.

The discussion on these subjects tended to limit unduly the economic aspects, with perhaps insufficient recognition of the technical and sociological advantages which the new techniques imply.

L. H. BEDFORD

TENSORS IN ELECTRICAL ENGINEERING

A RESIDENTIAL six-day course on "Tensors in Electrical Engineering", organized by the Extra-Mural Department, was held in the University of Liverpool during the Easter vacation. The lectures were given in one of the University halls of residence, where the students were accommodated. Twenty-five graduates from industry, government establishments and universities and colleges attended.

An introductory lecture was given by Dr. W. J. Gibbs, of the British Thomson-Houston Co., Ltd., and sixteen lectures were given by J. W. Lynn and

C. V. Jones, from the University Department of Electrical Power Engineering. Ample opportunity for discussion was available at the end of each lecture, and Dr. Gibbs encouraged and guided informal discussions each evening. The enthusiastic and often heated arguments which took place may be considered as a measure of the success of the course.

Since some of the students had no previous knowledge of tensor analysis, the opening lectures were devoted to the elements of matrix algebra and its application to electrical problems. The discussions showed that those to whom the subject was new were impressed by the practical nature of the method in its applications to numerical analysis. It was shown that the equation $V = ZI$ could be applied directly to complex circuits by replacing the quantities V, I and Z by the corresponding matrices. The use of compound matrices in obtaining the inverse of Z was explained and the delta-star transformation and Thevenin's theorem were included as special cases of matrix transformation.

The introduction of tensor analysis followed the general lines developed by Gabriel Kron, who in 1934 made the first of his significant contributions to the mathematical treatment of electrical machines and networks by tensor methods. It was shown that the simple transformation of co-ordinates in geometry or field analysis, $A^a = C^a_\alpha A^\alpha$, could be used in electrical systems for interconnecting the windings of machines and networks. The fact that power is invariant to such an interconnexion leads to the following equations: $I^\alpha = C^a_\alpha I^a$; $V_\beta = C^b_\beta V_b$; $Z_{\gamma\delta} = Z_{cd} C^c_\gamma C^d_\delta$;

where the Greek affixes indicate quantities in the new system. Since static networks form a holonomic electrical system, they can be analysed by tensor transformations. However, when windings are rotating with respect to each other they may have non-holonomic constraints, depending on the reference axes chosen. Some useful reference axes (such as those rotating with a synchronous flux wave) can be included only by use of non-holonomic equations. The general analysis of machines involves these more advanced concepts, which were next introduced. In particular, intrinsic and covariant derivatives of vectors and tensors are required. Stress was laid upon the work of Ricci, which showed that if in a differential equation which holds for rectangular Cartesian co-ordinates, ordinary derivatives be replaced by intrinsic derivatives and partials by covariant derivatives, then the modified equations hold for general curvilinear co-ordinates. The application of this theorem to electrical machinery is as follows. If the tensor equation of a stationary machine is

$$V_\alpha = R_{\alpha\beta} i^\beta + L_{\alpha\beta} \frac{di^\beta}{dt}$$

then when the machine is rotating the corresponding equation is

$$V_\alpha = R_{\alpha\beta} i^\beta + L_{\alpha\beta} \frac{\delta i^\beta}{\delta t}$$

where $\frac{\delta i^\beta}{\delta t}$ is the intrinsic derivative and

$$\frac{\delta i^\beta}{\delta t} = \frac{di^\beta}{dt} + \Gamma^\beta_{\gamma\alpha} i^\gamma i^\alpha$$

The general machine equation then becomes

$$V_\alpha = R_{\alpha\beta} i^\beta + L_{\alpha\beta} \frac{di^\beta}{dt} + \Gamma_{\beta\gamma,\alpha} i^\beta i^\gamma$$

The different forms of $\Gamma_{\beta\gamma,\alpha}$ which arise under different operating conditions and with different reference axes were next introduced. The terms arising because of non-holonomic constraints were studied in detail.

The long-established rules and concepts of the tensor calculus were seen to lead to a generalized theory of electrical machinery. The power and flexibility of these tensor applications, due to Kron, are becoming more widely recognized.

ROYAL BOTANIC GARDENS, KEW

REPORT FOR 1956

THE review of the work of the Royal Botanic Gardens, Kew, during 1956 follows the general pattern of earlier reports (*Kew Bull.*, No. 1 ; 1957). During the year Sir Edward Salisbury, who had been the director for thirteen years, retired and was succeeded by Dr. George Taylor, keeper of botany in the British Museum (Natural History).

The Herbarium staff, as usual, has dealt with a truly vast amount of material and has been visited by some 4,455 botanists, many of these from the Commonwealth and other countries overseas. The report also records extensive and varied inquiries on botanical matters and the receipt of many consignments of plants. The work on several floras has been sustained and constitutes a notable effort in scholarship.

In the Department of Economic Botany the number of inquiring visitors has been greater than in the previous year. Inquiries cover a great deal of ground, often of an interesting and important character. It would be impossible in a short note to do more than touch on one or two points. The distribution of economic plants still ranks as an important function of this section. The propagation of cacao was actively continued during the greater part of the year, and many plants were dispatched from the Quarantine House. These consisted chiefly of materials collected in Colombia during 1952 and forwarded to Kew in 1954 via the Imperial College of Tropical Agriculture in Trinidad. After the required period of supervision in quarantine, the plants were propagated as rooted cuttings, which were sent on to the West Africa Cacao Research Institute as materials for its breeding programme. It is noted that a variety of cacao from a widely different source, known as Lafi No. 7 from Samoa, has now been propagated and distributed. This material has aroused wide interest because of its reputation for high yielding capacity and its possible disease-resistance properties. Rooted cuttings have now been sent to Trinidad, West Africa and Malaya for trials under differing conditions. The work of the Quarantine House in relation to banana problems follows the lines reported on in previous years. Special interest is attached to some varieties of the diploid *Musa acuminata*, collected in New Guinea and Malaya, which in due course will be used in the breeding programme in the Caribbean.

An important result of the work of the Jodrell Laboratory is that a draft of practically the whole of a work on the anatomy of the grasses has been prepared and should, it is hoped, be ready for the press before the end of 1957; and anatomical studies of other monocotyledons have been published or are in progress. The routine work of the Laboratory is concerned with the very diverse, and sometimes diverting, materials submitted for examination: in 1956 a piece of wood from Herod's palace at Jerusalem was found to be *Juniperus oxycedrus*.

The report also deals comprehensively with the work in progress in the Gardens, including its several sections from the Arboretum to the Tropical House. It concludes with a record of the papers published during the year together with a staff list.

C. W. WARDLAW

THE CIVIL SERVICE

REPORT FOR 1956–57

THE ninety-first report of H.M. Civil Service Commissioners, covering the period April 1, 1956–March 31, 1957*, again notes a decrease in the number of candidates for the open competitions of the administrative class. Although the number of entries was the lowest since 1949 and only thirty-three out of the fifty vacancies allotted to this competition were filled, the entry for the 1957 competitions appears to be somewhat stronger both in number and in quality than that of 1956. To fill vacancies left by the 1955 open competition, a supplementary competition for the administrative class was held in the summer of 1956 to offer an opportunity to those who had remained at the universities for research, or had taken up other employment and had outstanding intellectual ability. Of the twenty-one candidates, the five who were successful had been engaged in research or in university teaching since graduating. The limited competition for the administrative class was somewhat more successful than in the previous year, and the results of the innovations tried seem encouraging. Recruitment to the statistician class remained difficult and the number competing for the special departmental class declined further. The open competitions for the executive class produced enough recruits to fill the vacancies notified, but it was only the adoption of a new competition based on the General Certificate of Education that maintained the level of recruitment among young people. The growing proportion of women candidates in some competitions, particularly those for the executive and clerical classes, suggests that the achievement of equal pay by 1961 is increasing the attractiveness for a woman of a career in the Civil Service. The method of continuous open competition was used for all scientific classes; and the results of the senior scientific officer/scientific officer competitions were relatively satisfactory, especially in the senior grade, for which recruitment appears to be easier than that of scientific officers of the quality and in the numbers required by departments. The greatest deficiency was in filling posts for scientific assistants, though a fair number of the vacancies are being filled by temporary people who are gaining the two years experience required to qualify them for the competitions.

The quality of candidates attracted by the research fellowship competition remains high, and the departments concerned appear to have been impressed very favourably by the work of those in the past. Of the twenty-seven fellowships offered this year, nine senior and thirteen junior fellowships have been awarded. Although the competition for patent examiners took a slight turn for the better, the number of vacancies is so large, and the problem of recruitment so difficult, that for a limited period candidates are being considered who hold honours degrees in non-scientific subjects. It remains as difficult as ever to recruit candidates with technical qualifications for the factory inspectorate. The information work of the Commission increased both in volume and in complexity and an information officer was appointed to organize and develop it. The arrangement made in 1955 whereby younger members of the administrative class act as links between the Civil Service and their own colleges or universities appears to fulfil a real need, and the arrangement made in December 1956 for sixty undergraduates, representing most of the British universities, to spend a week visiting Government departments also appeared to be a success.

ACCIDENTS IN CHILDHOOD

A YEAR ago the European Regional Office of the World Health Organization asked a group of experts from many countries to consider how accidents in childhood could be prevented. In most countries in Europe infant and child mortality has been steadily decreasing in recent years, and in many places has reached significantly low figures. Deaths due to infections and nutritional disturbances have fallen to a level considered unattainable only a few years ago. Against this, the death-rate due to accidents remains high and for many types of accidents has increased. As disease becomes more effectively controlled, accidents are assuming a proportionately greater importance. In some countries they have become the chief cause of death in childhood and adolescence and account for 30–40 per cent of all deaths in the age-group 1–19 years. Among certain groups of children, greater numbers are killed by accidents than by all other causes combined. This unenviable prominence of accidents in child mortality throughout Europe is due to the new and dangerous hazards introduced into many homes and countries by modern technological progress. The spread of electrification, especially in rural areas, the introduction of highly potent insecticides, the increasing numbers of motor-cars and bicycles on roads designed for thirteenth- to fifteenth-century traffic, may be cited as examples.

It is not only as a cause of death that accidents in childhood are important. The number of non-fatal accidents is very much larger—100–200 times greater and by some estimates even more.

In a preliminary survey the advisory group examined the main causes of accidents and at what ages they occurred*. These showed that mortality from accidents is highest at the pre-school age, lowest among school children, and again somewhat higher in adolescence. Since the beginning of this century, mortality from accidents has decreased for the pre-school group, remaining at almost the same level in the school-age and adolescent groups. The decrease in pre-school age accident mortality took place in spite of a growing traffic accident toll, as a result of diminishing deaths from drowning and burns and scalds. In school age and adolescence, the increasing traffic accident mortality cancelled out the decrease in deaths from other accidental causes.

---

* World Health Organization Technical Report Series, No. 118: Accidents in Childhood: Facts as a Basis for Prevention. Report of an Advisory Group. Pp. 40. (Geneva: World Health Organization; London: H.M. Stationery Office, 1957.) 1 Swiss franc; 1*s*. 9*d*.; 0·30 dollars.

The main groups of fatal accidents in children are those caused by motor-vehicles, drowning, and fire and burns, the proportion varying from one country to another. Accident mortality was found to depend upon the peculiarities of the situation in which the population was living. In some countries, for example, although the number of motor-vehicles in use is rising, the accident-rate is not increasing in like proportion.

Analysis by sex as well as age reveals important differences. The aggregate accident mortality in the European region shows that the rates for boys are double or triple those for girls at most ages. The least difference is observed at the younger ages. There is a marked preponderance among boys and male adolescents of injuries associated with outdoor activities, and among girls of burning accidents caused through the wearing of light inflammable clothing.

Not unexpectedly, the group found that mortality data do not in themselves give a complete indication of frequency or of social and economic consequences of accidents. Morbidity data is required to complement mortality statistics and to expose potentially dangerous accidents. While mortality from accidental poisoning is low in most countries, morbidity studies have revealed a high frequency of accidental poisoning. Morbidity studies also show that a certain attitude of carelessness and instability of purpose are much more prevalent among those children who have had accidents. Children of this type often come from broken homes or problem families; their recklessness and disregard of consequences is primarily a mental factor which may at times express itself in physical behaviour resulting in unforeseen accidents.

The advisory group was unable to make detailed examination of the possible methods of preventing accidents to children but, in principle, showed that the bases of accident prevention fall into three categories: education; engineering; regulation and law enforcement. At present much of the organized accident prevention work for children in Europe is directed to traffic and road safety; such activities should be increased in view of the growing importance of motor-vehicles as a cause of injury to children. A substantial number of programmes should also be directed to safety in the home and its vicinity and to the prevention of drowning accidents. Many of the organizations which at present limit their efforts to traffic-safety campaigns could with advantage turn their attention to other hazards of childhood and undertake preventive measures in co-operation with those who are primarily concerned with child welfare. In one country, for example, the pædiatricians, working through their national and local committees, have been largely instrumental in developing, in co-operation with the pharmaceutical industry, measures to minimize the hazard from aspirin poisoning and, in co-operation with paint manufacturers, a standard for a paint which is safe for use on children's toys, furniture and interior surfaces. Pædiatricians in some countries, because of their special interest in the infant and pre-school child, have led the movement to focus attention on accident prevention in this age-group—the least accessible to organized safety education and yet the one with the highest accident mortality-rates of childhood. Physicians who supervise the health of infants and children, public health nurses, nursery school teachers, and others with access to the family and homes of these small children, have begun to give guidance in accident prevention as a part of their instruction in child care. For some years past, schools in many countries have been giving training in road safety. Some countries provide instruction in swimming and first-aid and on the safe use of the bicycle. The use of the home safety check-list, taken home by the school-child, is a part of the safety programme of some school systems.

RELATIONSHIP BETWEEN THE HYDROLYSIS OF ADENOSINE TRIPHOSPHATE AND OXIDATIVE PHOSPHORYLATION

By W. C. HÜLSMANN and PROF. E. C. SLATER
Laboratory of Physiological Chemistry, University of Amsterdam

IN a recent preliminary communication[1] from this Laboratory it was reported that liver and heart mitochondria contain four different enzyme systems which bring about the hydrolysis of added adenosine triphosphate. Three of these systems, designated by their pH-optima 6·3, 7·4 and 8·5, were stimulated by dinitrophenol. It was suggested that these three different adenosine triphosphatases might be related to the three dinitrophenol-sensitive phosphorylative steps in the respiratory chain. An earlier formulation[2] of the oxidative phosphorylation was expanded into

$$AH_2 + B + I \rightleftharpoons A \sim I + BH_2 \qquad (1)$$

$$A \sim I + X \rightleftharpoons X \sim I + A \qquad (2)$$

$$X \sim I + \mathrm{ADP} + H_3PO_4 \rightleftharpoons X + I + \mathrm{ATP} \qquad (3)$$

$$X \sim I + H_2O \xrightarrow{(\mathrm{DNP})} X + I \qquad (4)$$

Reaction (1) represents the hydrogen (or electron) transfer reaction in which energy is conserved by combination of the oxidized product with I; reaction (2) is an energy-transfer reaction; while reaction (3) is the phosphorylation reaction. It is supposed that

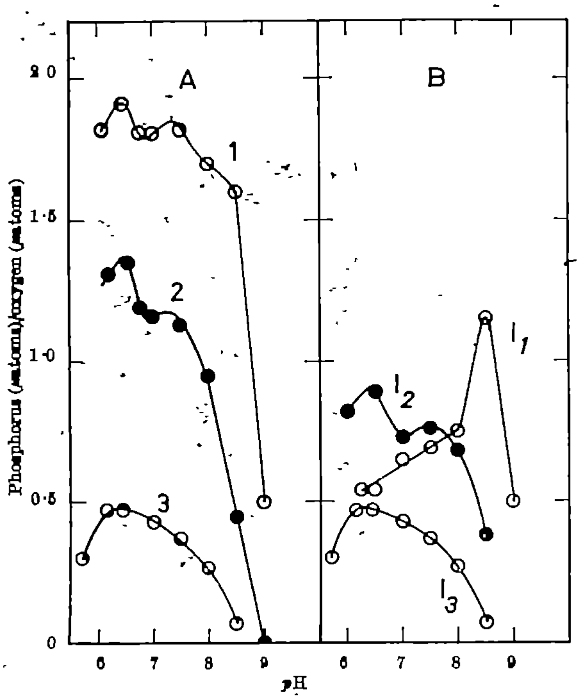

Fig. 1*A*. The effect of *p*H, on the phosphorus/oxygen ratio measured with guinea pig heart mitochondria (sarcosomes) and ascorbate (curve 3), succinate (curve 2) and DL-glutamate (curve 1) as substrate. In every case, the reaction mixture contained tris-acetate buffer, 0·05 *M*; magnesium, 0·005 *M*; glucose, 0·01 *M*; adenosine triphosphate, 2×10^{-4} *M*; phosphate, $2·25 \times 10^{-3}$ *M*, ethylenediamine tetraacetate, 6×10^{-4} *M*; potassium chloride, 0·03 *M*; sucrose (except with ascorbate), 0·05 *M*; hexokinase; sarcosomes 0·26–0·4 mgm. protein/ml. Cytochrome *c* ($1·65 \times 10^{-4}$ *M*) was used only with ascorbate. Concentrations of substrates were: ascorbate, 0·03 *M*; succinate, 0·05 *M*; DL-glutamate, 0·01 *M*. Curves 1 and 2 represent the means of two experiments, in which both substrates were studied with the same mitochondrial preparations. Curve 3 is the mean of two experiments with two other mitochondrial preparations, treated under hypotonic conditions as described in ref. 6

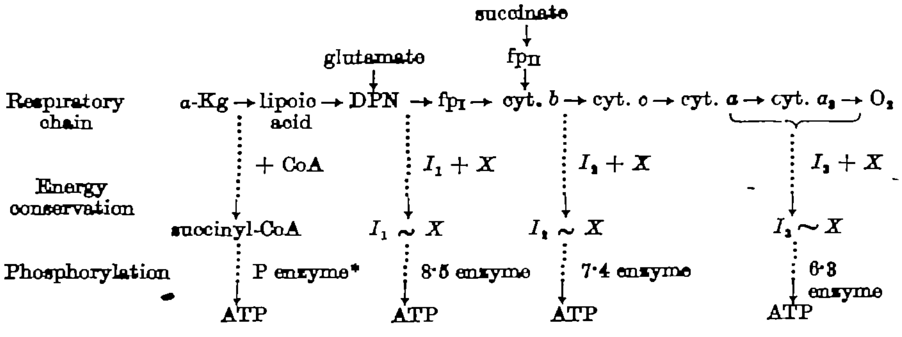
Fig. 1*B*. The *p*H-activity curves of each phosphorylative enzyme, calculated as described in the text

reaction (4) is absent in intact liver mitochondria, but becomes very fast in the presence of dinitrophenol. Added adenosine triphosphate is then hydrolysed by the reverse of reaction (3), followed by reaction (4). The three dinitrophenol-sensitive enzymes have *p*H optima characteristic of three different reactions (3), involving three different *I*'s (I_1, I_2 and I_3). The same X could be concerned in all reactions.

Since reaction (3) in the forward direction is responsible for oxidative phosphorylation, this explanation implies that, in certain circumstances, the latter will show the same *p*H-optima. This would not be expected when reaction (4) is lacking, as in intact mitochondria, since each molecule of AH_2 oxidized must then be accompanied by the synthesis of one molecule of adenosine triphosphate, and the phosphorus/oxygen ratio would be independent of the *p*H. When, however, reaction (4) is operative, the phosphorus/oxygen ratio of each phosphorylative step equals {rate of reaction (3)}/{rate of reaction (3) + rate of reaction (4)}, and might be expected to show the *p*H-dependence of reaction (3). This has been found to be the case with heart mitochondria (sarcosomes) which, in our hands, give phosphorus/oxygen ratios appreciably below those found with liver mitochondria. In the experiments shown in Fig. 1, hexokinase was added to trap the adenosine triphosphate, and so prevent reaction (3) proceeding from right to left.

The *p*H activity curves of the phosphorus/oxygen ratio (Fig. 1,*A*) show three peaks with glutamate (at *p*H's about 6·4, 7·4 and 8·5), two with succinate (at about 6·4 and 7·4) and one with ascorbate (6·3). The number of peaks corresponds to the number of phosphorylative steps associated with these three substrates, and the *p*H-optima for oxidative phosphorylation are the same as those found for the dephosphorylation of adenosine triphosphate in the presence of dinitrophenol. This is very strong support for the suggestion of Hunter and Lardy[3] that the two phenomena are related (see also ref. 4), and for the type of mechanism represented by equations (1)–(4) above. Our findings completely disprove an alternative hypothesis for the mechanism of action of dinitrophenol, namely, that the uncoupling of oxidative phosphorylation is a consequence of the increased hydrolysis of adenosine triphosphate. If this were true, phosphorylation would have minima not optima at *p*H's where the hydrolysis is optimum.

Our results also enable us to locate the *p*H-optima of the three different phosphorylation reactions in the respiratory chain. The 6·3 enzyme, which is common to all three substrates, must be associated with the cytochrome oxidase end of the chain. The 8·5 enzyme is found with glutamate, but not with succinate or ascorbate, and must, therefore, be associated with the phosphorylation in the region of



* See ref. 5.

(The following abbreviations are used: α-Kg, α-ketoglutarate; DPN, diphosphopyridine nucleotide; fp_I, flavoprotein (diaphorase); fp_{II}, flavoprotein (succinic dehydrogenase); cyt., cytochrome; CoA, coenzyme A; ATP, adenosine triphosphate.)

diphosphopyridine nucleotide which is not concerned in the oxidation of succinate or ascorbate. The 7·4 enzyme, which is found with both glutamate and succinate, but not with ascorbate, must lie somewhere in the middle of the respiratory chain.

Although the oxidation-reduction steps in the respiratory chain which are linked with phosphorylation are not yet definitely identified, there is increasing evidence that they are located as in the accompanying scheme. (The role of cytochrome-*b* in the main chain is still doubtful.) The horizontal arrows represent the hydrogen (or electron) transfer reactions (1). The two sets of vertical dotted arrows represent the energy conservation and transfer in reactions (1) and (2), and the phosphorylation reactions (3). The nature of I_1, I_2, I_3 and X remains completely unknown. In the substrate-linked phosphorylation with α-ketoglutarate, which is not affected by dinitrophenol, coenzyme A takes the place of both I and X.

The *p*H-activity curves of each phosphorylation reaction are illustrated in Fig. 1,*B*. (Strictly speaking, the curves in Fig. 1,*B* represent the effect of *p*H on the ratio {rate of reaction (3)}/{rate of reaction (3) + rate of reaction (4)}. The curve marked I_3 is the same as the curve with ascorbic acid in Fig. 1,*A*. The curve marked I_2 is the difference curve between those with succinate and ascorbate in Fig. 1,*A*. The fact that curve I_2 shows a peak at 6·4 as well as at 7·5 is understandable, since it is probable that the phosphorus oxygen ratio in the cytochrome oxidase step was higher when succinate was substrate than when ascorbate and cytochrome *c* were used. In the latter case, it is necessary to use swollen mitochondria and added cytochrome *c*. The curve marked I_1, the difference curve between those with glutamate and succinate in Fig. 1,*A*, shows a particularly sharp peak at 8·5.

Further details will be published later.

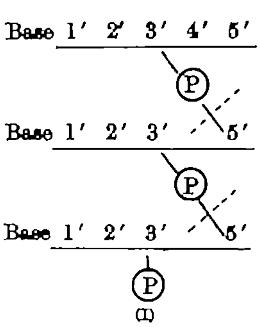
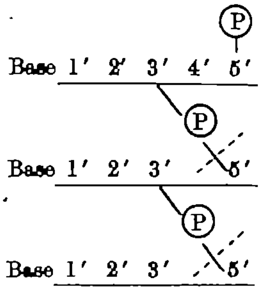
TERMINAL GROUPS OF TOBACCO MOSAIC VIRUS NUCLEIC ACID

In ribonucleic acids the nucleotides appear to be held together by phosphodiester links between the 3′ and 5′ carbons of adjacent sugar residues[1]. The polynucleotide chains thus formed may be terminated with a single phosphoryl residue in either of two ways as shown diagrammatically in (I) and (II).



(I)



(II)

According to the theory of Brown and Todd[2], compound II on hydrolysis with alkali splits as indicated by the dotted lines to yield a nucleoside diphosphate from one end and a nucleoside from the other end, whereas compound I yields only nucleoside 3′-phosphates. Markham, Matthews and Smith[3] reported considerable amounts of nucleosides and nucleoside diphosphates in the alkali-fission products of ribonucleic acid of tobacco mosaic virus. On the basis of this observation, they concluded that in tobacco mosaic virus ribonucleic acid there is a large proportion of chains of type II, and since it was calculated that about one residue in fifty yields a nucleoside diphosphate, the size of the nucleic acid was estimated to be much smaller than that reported by Cohen and Stanley[4]. These observations are of importance, not only because they suggest that there are two types of ribonucleic acid in viruses, but also because of considerable interest in the essential size of the ribonucleic acid from tobacco mosaic virus in relation to its recently reported infectivity[5,6]. Therefore, an attempt was made to confirm the results of Markham *et al.*[3] employing both intact tobacco mosaic virus and isolated nucleic acid preparations.

The tobacco mosaic virus used in these studies was grown in Turkish tobacco plants and was purified by the differential centrifugation method. Ribonucleic acid from it was prepared by two different procedures: (1) a heat denaturation method[7] and (2) the phenol procedure[6]. Both the ribonucleic acid preparations had about 1 per cent of the infectivity of an equal weight of virus.

For direct determination of the alkaline hydrolysis products from the ribonucleic acid, without isolating it, the intact virus was treated as follows. To 400 mgm. of tobacco mosaic virus was added 2 ml. *N* potassium hydroxide and the mixture was incubated at room temperature (23° C.) for 18 hr. The protein was precipitated at 0° C. by the addition of ice-cold perchloric acid to *p*H 1·0 and centrifuged in the cold. The precipitate was washed four times with distilled water. The combined supernatant fluids were neutralized with ammonium hydroxide and lyophilized. The lyophilized material was taken up in 0·5 ml. *N* ammonium hydroxide. 0·3 ml. of this was subjected to paper chromatography using *iso*-propanol/water/ammonia as a solvent system[8] and 0·2 ml. to paper electrophoresis using *M*/20 phosphate buffer[3] at *p*H 7·4.

The two nucleic acid preparations were treated as follows. To 20 mgm. of nucleic acid was added

1 ml. N potassium hydroxide and the mixture incubated at room temperature (23° C.). The products of hydrolysis were processed and were subjected to paper chromatography and paper electrophoresis in the manner described above.

Only nucleotides were observed in all cases, and neither nucleosides nor nucleoside diphosphates were found in the alkali-fission products of the intact tobacco mosaic virus or of the two ribonucleic acid preparations made from it.

In addition, a test was made to evaluate the sensitivity of the method for detecting diphosphates as follows. Twenty-four micrograms of uridine-3',5'-phosphate (kindly supplied by Dr. C. A. Dekker) were added to 10 mgm. of nucleic acid and treated with 1 ml. N potassium hydroxide as above. The products of hydrolysis were treated as before and subjected to paper electrophoresis. It was found that 85 per cent of the added uridine-3',5'-phosphate could be recovered. On the basis of this, one may conclude that it is possible to determine nucleoside-5'-phosphate ends with an error of 15 per cent, even if there is only one such end in about 500 nucleotide residues, that is, one-tenth as many as reported by Markham *et al.*[3]. Furthermore, since it is possible readily to detect qualitatively one-half this quantity of diphosphate, it can be concluded that tobacco mosaic virus nucleic acid of the size reported by Cohen and Stanley[4] (molecular weight about 300,000), and represented by our heat denatured ribonucleic acid, seems not to end in 5'-phosphate groups.

These findings are in contrast to those of Markham *et al.*[3] and greatly reduce the probability that the ribonucleic acid of tobacco mosaic virus can be represented by chains of type II. On the other hand, the easy demonstration of 3'-phosphate ends in experiments employing phosphomonoesterase treatment (Markham *et al.*[3], and our unpublished observations) leads to the conclusion that the nucleic acid of tobacco mosaic virus is probably of type I.

If tobacco mosaic virus ribonucleic acid is type I, it would be valuable to determine the number of 3'-phosphate terminal groups. However, the phosphomonoesterase treatment for 18 hr. at 37° C. at pH 5·3 as used by Markham *et al.*[3] was found unreliable in a quantitative sense with our ribonucleic acid, because the conditions alone, without any esterase, caused a partial degradation of the ribonucleic acid to yield dialysable fragments and, of course, new end-groups. This was demonstrated as follows. 5·49 mgm. of tobacco mosaic virus ribonucleic acid prepared by heat denaturation of the virus[7] was dissolved in 0·8 ml. of $M/10$ acetate buffer of pH 5·3 and dialysed against 1 ml. of $M/10$ acetate buffer of pH 5·3 for 18 hr. at 37° C. (a few drops of toluene were added to prevent bacterial growth). The dialysate was concentrated to dryness at 50° C. by blowing in a current of nitrogen and the residue was digested with 70 per cent perchloric acid[9] and phosphorus was determined[10]. It was found that 1·14 per cent of the nucleic acid had broken down and passed through the dialysis bag under these conditions. Thus the incubation procedure used by Markham *et al.*[3] creates more end-groups than were originally present, and it appears that a precise determination of 3'-phosphate ends will require first the establishment of conditions for stabilizing the nucleic acid.

In summary, we have not been able to confirm the results leading to the conclusion that tobacco mosaic virus ribonucleic acid represents a type of nucleic acid characterized by 5'-phosphate ends or that it is substantially smaller than the early estimates[4]. On the other hand, our results are consistent with those expected from nucleic acid characterized by 3'-phosphate ends.

This investigation was supported by grants from the Rockefeller Foundation and the Lederle Laboratories Division, American Cyanamid Company, and a research grant, E-634, from the National Institutes of Health, United States Public Health Service.

Markham, Matthews and Smith[1] have given evidence for the existence of ribonucleic acid chains terminated by nucleoside residues bearing singly esterified 5'-phosphate groups. They found that alkaline hydrolysis of certain ribonucleic acids, including that from tobacco mosaic virus, yielded small amounts of nucleoside-5',3' (or 2') diphosphates and nucleosides in addition to the nucleoside 3'- and 2'-monophosphates. The nucleoside diphosphates originate from terminal nucleoside residues bearing 5'-phosphomonoester groups, while the nucleosides come from residues at the other end of the chain bearing no singly esterified phosphates. The relative proportions of these products in alkaline hydrolysates of tobacco mosaic virus ribonucleic acid led to the conclusion that this nucleic acid had a mean chain-length of 50 nucleotide residues.

Further investigation of tobacco mosaic virus nucleic acid has shown that the latter conclusion is erroneous, and that while short polynucleotide chains bearing 5'-phosphomonoester end-groups may be associated with some virus preparations, they are not an intrinsic part of the virus.

Tobacco mosaic virus was grown on Turkish tobacco plants and purified by a differential centrifugation procedure. Nucleic acid was prepared by two methods: heat denaturation[2], or treatment with sodium dodecyl sulphate[3]. The nucleic acid preparations were hydrolysed in N potassium hydroxide for 18 hr. at 20°. After neutralization with perchloric acid and removal of insoluble potassium perchlorate, the hydrolysates were run on paper electrophoresis, either at pH 5 in 0·1 M acetate buffer, or at pH 9 in 0·05 M borate buffer. Both methods serve to separate the nucleosides and nucleoside diphosphates from the nucleoside-2'- and 3'-monophosphates. The quantities of hydrolysate used were such that nucleoside diphosphates in amounts of 0·1 per cent of the mononucleotides could easily have been detected. No nucleoside diphosphates were found in hydrolysates of either of the two types of nucleic acid preparations.

We attempted to establish the nature of the material giving rise to nucleoside diphosphates previously observed in tobacco mosaic virus preparations isolated by ammonium sulphate precipitation. Eight strains of tobacco mosaic virus described by Siegel and Wildman[4] were chosen, because these strains differ in the amounts of coloured material present in the purified virus preparations. They were grown in White Burley tobacco plants, and the virus isolated by heat clarification of the plant sap followed by ammonium sulphate precipitation. The virus nucleic acids were prepared by heat denaturation[3]. Alkaline hydrolysates of nucleic acid preparations from all the strains contained nucleoside diphosphates and nucleosides, but the proportion of nucleoside diphosphates/mononucleotides (0·1–1 per cent) varied not only among the strains but also with different preparations of the same strain. There was no correlation between the amounts of nucleosides and nucleoside diphosphates in the hydrolysates, nor were these related to the presence of coloured material in preparations of some of the virus strains. On dialysis at 37° against 0·1 *M* citrate buffer *p*H 7 (a procedure similar to that used by Ginoza, Atkinson and Wildman[5] to remove non-viral nucleoprotein) and subsequent isolation of the virus by centrifugation, almost all the material giving rise to nucleoside diphosphates on alkaline hydrolysis could be removed from the virus. The properties of this material suggest that, if it is a polynucleotide, it is of low molecular weight. However, it cannot be separated from the virus by centrifugation before incubation with the citrate buffer and appears to be associated with the virus particles or other high-molecular weight material present in virus preparations obtained in this way.

These observations show that there is no evidence that tobacco mosaic virus nucleic acid consists of chains terminated by 5′-phosphomonoester end-groups.

GENETICS OF THE β-LACTOGLOBULINS OF COW'S MILK

By R. ASCHAFFENBURG and J. DREWRY

Chemistry Department, National Institute for Research in Dairying, University of Reading

THE occurrence of different β-lactoglobulins in cow's milk has been briefly reported[1]: by means of paper electrophoresis at *p*H 8·6, the milk of individual animals was shown to contain either two components ($\beta_{1,2}$), or only the faster-moving (β_1) or slower-moving (β_2) of these. The preliminary results suggested that the formation of these proteins is controlled by a single gene, and we now present more extensive evidence in support of this hypothesis.

The terms β_1- and β_2-lactoglobulins were first used by Polis, Shmukler, Custer and McMeekin[2] for describing subfractions of crystalline β-lactoglobulin prepared from bulk milk. As these subfractions are different from the components present in the milk of individual cows[3], changes in nomenclature are now proposed. These have been chosen so as to bring the notation into line with genetical usage. The proteins should be called β-lactoglobulin A (instead of β_1), B (instead of β_2) and *AB* (instead of $\beta_{1,2}$). Animals can then be described as of phenotype β-lactoglobulin A/A, B/B or A/B, and of genotype Lg^A/Lg^B, etc., using *Lg* as the locus symbol for the single gene believed to be involved.

The samples to be subjected to paper electrophoresis for typing purposes were prepared by a modification of our procedure[4,5] for the isolation of the crystallizable proteins of milk. As in this procedure, a filtrate containing the 'lactalbumins' is first obtained by adding sodium sulphate to whole milk (20 gm./100 ml.). The 'lactalbumins' are then precipitated with ammonium sulphate (20 gm./100 ml.), collected on a filter paper, dissolved in a little distilled water, and finally dialysed for at least 90 min. against running tap-water. By starting the fractionation in the morning, samples can be conveniently prepared for electrophoresis overnight.

This typing procedure has been applied to the milk of nearly 300 cows. Most of the animals, including 24 pairs of one-egg twins, have come from the Institute herds. The results obtained with 278 cows, subdivided according to breed, are given in Table 1. On the assumption that the genotypes correspond with the observed phenotypes, the gene frequencies have been obtained by counting. Under conditions of random mating, and in the absence of strong selective effects, application of the Hardy–Weinberg formula should then result in close agreement between the observed numbers and those expected from the theory of genetic equilibrium. As shown in Table 1, such agreement is, in fact, obtained, and this applies not only to the total population, but also to all but one of the rather small sub-groups. It holds, in particular, for the Shorthorn population, and it is, perhaps, of interest that all the animals included in this group are descendants of stock established at the Institute for well over thirty years. In view of these

§ Cross-breeds, etc.

findings, the secretion of the different β-lactoglobulins may be regarded as an example of a metabolic polymorphism of the type in which, according to Allison[5], "allelomorphic genes give rise to distinct products, both of which are present in the heterozygote".

This interpretation is supported by the available family data. Thus, no homozygote A/A was found when the daughters of 34 dams of phenotype B/B were tested; 20 of the offspring were B/B and 14 A/B. (There were only two dams of phenotype A/A; both had daughters of type A/B.) A difficulty in the interpretation of the genetics of this situation is the inability to assess the phenotype of males. However, it has been possible to infer the genotype of some of the more widely used Shorthorn and Friesian bulls from their breeding record. One such record is shown in Table 2, which permits, for example, from matings Nos. 1 and 2, or 6 and 8, the deduction that the bull in question is of genotype Lg^A/Lg^B. From such data, the segregation patterns in Table 3 have been obtained. The number of cases in the different groups is small, but the table does show that the proportions of offspring belonging to different phenotypes agree well with expectation. Thus, the family data support the conclusion drawn from the results of the gene-frequency analysis.

Table 2. FAMILY DATA FOR FRIESIAN BULL H.B.

* Since bulls cannot be classified with certainty as Lg^A/Lg^A or $Lg^B Lg^B$, combinations involving such bulls must be regarded as probable mating types.

That the secretion of the different β-lactoglobulins is under strict genic control is further emphasized by the findings with one-egg twins, of which twenty-four sets have now been tested. Without exception, the twins in each set produced the same form of β-lactoglobulin. In contrast, four out of five pairs of two-egg twins were found to secrete different β-lactoglobulins. As a diagnostic aid in the testing of twin cattle, β-lactoglobulin typing is clearly of limited value: it can only be applied to the lactating female, and the results can only be used to disprove that twins are monozygous. One-egg twins collected by our Institute are subjected to blood-grouping tests at the Institute of Animal Breeding, Royal Agricultural College of Sweden, Upsala, using the technique described by Rendel[6]. Inspection of the blood-grouping records of the twins of known β-lactoglobulin type has not disclosed any simple and obvious relationship between the blood-groups and the β-lactoglobulin types, but the number of comparisons is small, and the existence of linkage cannot be ruled out.

In this connexion, recent work on hæmoglobin types in cattle deserves brief discussion. As first shown by Cabannes and Serain[7], cattle blood may contain two electrophoretically distinct hæmoglobins either singly or in combination, but it appears from a survey of British breeds[8] that this applies to only one of the four such breeds tested for β-lactoglobulin, the Guernsey, whereas in the remaining three (Ayrshire, Friesian and Shorthorn) only a single hæmoglobin has been found. As all four breeds are polymorphic with respect to β-lactoglobulins, the gene controlling the formation of the milk proteins is probably unrelated to that governing hæmoglobin synthesis. Like cattle, goats[9] and sheep[9,10] are also known to produce two types of hæmoglobin, while a whole series of hæmoglobin types has been discovered in human blood. The question whether similar genetically controlled differences are to be found in the milk proteins of species other than cattle is under investigation.

Since β-lactoglobulins A and B are distinctly different proteins[1,2], they are likely to differ in some of their effects. In searching for the possible physiological significance of such differences, it must be borne in mind that, under natural conditions, milk is produced in order to nourish the young, so that differential effects may have to be sought in the calf that receives the milk rather than in the cow that secretes it. Too little is, as yet, known about the

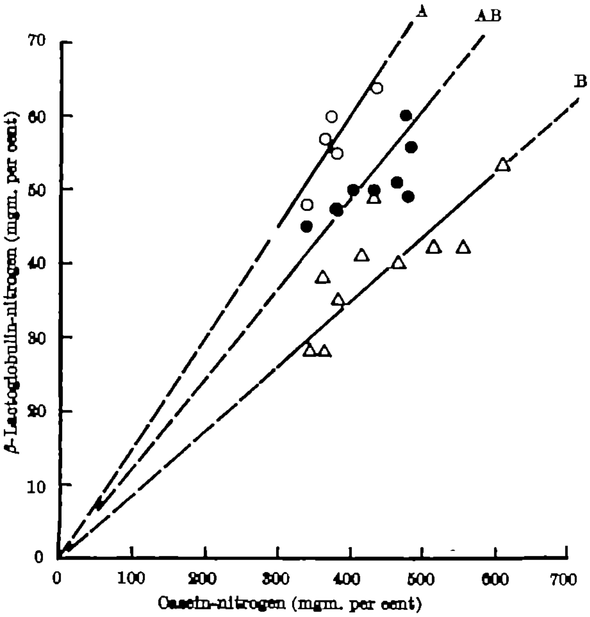

Fig. 1. Concentration of the β-lactoglobulins and of casein in the milk of 24 individual cows

detailed composition of the β-lactoglobulins to consider possible qualitative differences, such as might arise from variations in the amino-acid composition of the proteins. That there are considerable quantitative differences in their output is shown by the following results. These have been obtained by determining the concentration of the β-lactoglobulins, using a newly developed analytical procedure (Aschaffenburg, R., and Drewry, J., unpublished work), and of casein, using Rowland's method[11], in the milk of single cows of different breed, age and state of lactation (excluding the colostral stage).

By plotting β-lactoglobulin against casein concentration for each specimen, as shown in Fig. 1, some marked regularities are brought out. The concentration of each of the β-lactoglobulins varies in proportion to the casein content, the relation being different for each type. This suggests some form of quantitative relationship between β-lactoglobulin and casein synthesis, possibly during the early stages of their build-up from a common amino-acid pool. By fitting linear equations to the data, as shown in the figure, the following slope constants were obtained: $k_A = 0{\cdot}150$; $k_{AB} = 0{\cdot}122$; $k_B = 0{\cdot}087$. These findings indicate that, given equal yields of milk of comparable casein content, an animal homozygous for the Lg^A-allele will produce almost twice as much β-lactoglobulin as the other homozygote, while the output of the heterozygote falls about half-way between that of the two homozygotes. If the β-lactoglobulins are synthesized for a specific nutritional purpose, it might be concluded that the enhanced capacity for β-lactoglobulin production conferred by the Lg^A-allele would be advantageous to the calf. Yet in all the cattle breeds tested the frequency of Lg^B is higher than that of Lg^A. The simplest explanation, from the point of view of population genetics, for the stability of such a polymorphism is that the relative fitnesses of the three genotypes are as follows: Lg^A/Lg^B, Lg^B/Lg^B, Lg^A/Lg^A. Thus it seems that the β-lactoglobulins may have some other physiological effects which influence the selective values of the several genotypes.

We wish to thank Dr. A. C. Allison (Oxford) for generous help and guidance.

HISTOCHEMICAL APPEARANCES OF CHOLINESTERASE IN THE NORMAL SCIATIC NERVE AND THE CHANGES WHICH OCCUR AFTER NERVE SECTION

By Dr. R. S. SNELL
Department of Anatomy, King's College, London

It has been reported on many occasions that cholinesterase is highly concentrated in nerve fibres. Sawyer[1] showed by chemical analysis that the sciatic nerve in the guinea pig contains a large amount of cholinesterase, and approximately 57 per cent of this is true cholinesterase while the remainder is pseudo-cholinesterase. Koelle[2] found by histochemical examination that in the cat, rabbit and rhesus monkey high concentrations of true cholinesterase were located in the cholinergic neurones and lower concentrations in the adrenergic and sensory neurones. Giacobini[3] also investigated the problem on nervous tissue from the frog, rat and cat, using a modification of the Koelle method. He found that neurones, which had been isolated by microdissection from spinal, sympathetic and parasympathetic ganglions and from the anterior and lateral horns of the spinal cord, contained large concentrations of true cholinesterase in the cytoplasm and nerve processes. The results showed that in these different types of cells there was a high concentration of true cholinesterase in the cytoplasm at the axon hillock and at the surface of the axon. The majority of the nerve fibres isolated from the anterior roots of spinal nerves of the rat also showed a high concentration of true cholinesterase. Attempts to evaluate the degree of true cholinesterase activity in the different parts of the axon (root, node, internode) using isolated fibres from the frog's sciatic nerves did not give any valid results. Nachmansohn[4] is of the opinion that the presence of cholinesterase in nerve fibres is intimately related to the propagation of nerve impulses along the axons.

The present investigation was designed to demonstrate histochemically the distribution of cholinesterase in a mixed peripheral nerve and to study the effect of nerve section on the concentration and distribution of this enzyme in the individual nerve fibres.

Forty-six mature guinea pigs were used for this investigation. Twelve of the animals were used for studying the distribution of cholinesterase in the normal sciatic nerve. In seventeen of the animals the right sciatic nerve was cut in mid-thigh and a portion about 1 cm. long was removed. In the remaining seventeen animals the right sciatic nerve was also cut, but the two ends were immediately approximated by means of a single fine silk suture. Animals from the last two groups were killed at intervals over a period of six weeks following the operation. The sciatic nerves were removed from each guinea pig and in the case of those which had had the right sciatic nerve cut the left normal nerve was also removed to serve as a control. The nerves were fixed in 10 per cent formol saline for 15 hr. Longitudinal frozen sections 30μ thick were then cut. Transverse sections were also cut of the normal nerves at 50μ thick after they had been impregnated with a dilute solution of gum arabic for one hour. The sections were washed in distilled water for half an hour and then processed using a modification of the histochemical technique described by Koelle and Friedenwald[5]. The sections were incubated with the substrate solutions for 48, 72 and 96 hr. at pH 4·2. The cholinesterase appearances in the sciatic nerves were assessed by studying the concentration and distribution of the copper sulphide precipitate formed. In order to distinguish between the cholinesterase group of enzymes and the other esterases a number of the nerve sections were treated with incubating solutions also containing 3×10^{-5} *M* concentrations of eserine. The results were as follows.

Appearances of cholinesterase in the normal sciatic nerve. Cholinesterase was found to be concentrated mainly in the axons and in the neurilemmal sheaths. In the axons the cholinesterase appeared to be evenly distributed along their lengths and throughout their breadths. In the neurilemmal sheaths the enzyme was seen to be evenly distributed throughout the Schwann cells, and in the transverse nerve sections appeared as a black ring around each axon (Fig. 1). No obvious difference in the concentration of cholinesterase could be detected in the nerve fibres of differing diameters. A small amount of cholinesterase was found in the connective tissue between the nerve fibres. In those sections which had been incubated with substrate solutions containing eserine no enzyme activity could be detected.

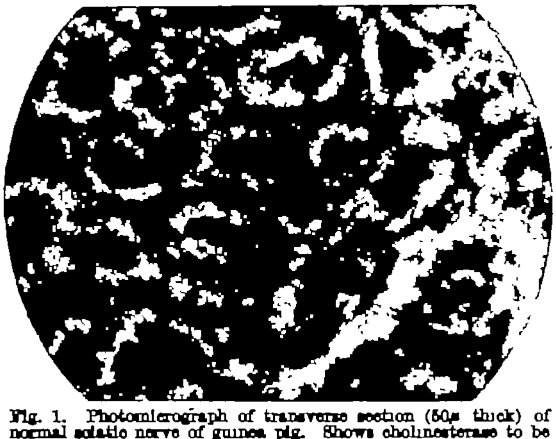

Fig. 1. Photomicrograph of transverse section (50μ thick) of normal sciatic nerve of guinea pig. Shows cholinesterase to be concentrated mainly in the axons and in the neurilemmal sheaths. The cholinesterase appears black in the photomicrograph. Stained histochemically for cholinesterase. No counterstain used. × 1,870

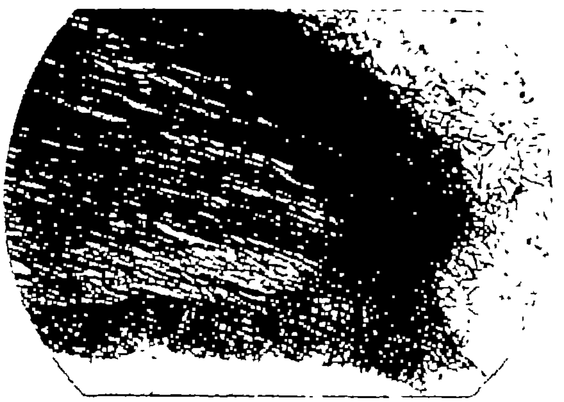

Fig. 2. Photomicrograph of longitudinal section of proximal portion of sciatic nerve of guinea pig 20 days after nerve section and suture. Shows large number of neurofibrils growing out of the proximal stump containing a very high concentration of cholinesterase. The cholinesterase appears black in the photomicrograph. Stained histochemically for cholinesterase. No counterstain used. × 145

Appearances of cholinesterase in the sciatic nerve following nerve section. In the nerves which had been cut and not sutured the concentration of cholinesterase in the proximal portion remained normal, while in the distal portion the cholinesterase became reduced in amount as degeneration proceeded. When regeneration commenced the nerve fibrils growing out of the proximal stump were found to contain a very high concentration of cholinesterase (Fig. 2), much greater than that seen in the normal nerve; and similar appearances were noted in the nerve fibrils growing into the peripheral neurilemmal tubes in the nerves which had been cut and sutured. In those sections which had been incubated in substrate solutions containing eserine no enzyme activity was seen.

The high concentration of cholinesterase seen in the nerve fibrils growing out of the proximal stump would account for the high concentration of this enzyme found by chemical analysis in the neuroma of the proximal stump by Couteaux and Nachmansohn[6] and by Sawyer[1]. Furthermore, the fall in concentration of cholinesterase in the peripheral stump during Wallerian degeneration is almost certainly due to the disintegration of the axis cylinders, since only a small amount of residual cholinesterase was seen in the peripheral neurilemmal tubes. In these investigations no distinction was made between true and pseudo-cholinesterase.

I gratefully acknowledge the technical assistance of Miss J. M. Burke with this work.

Hole and Claw Defects in Graphite

IN the ideal crystal, graphite consists of infinite sheets of fused aromatic rings, packed in parallel and with hexagonal symmetry of the atoms. Actual crystals of graphite show various types of departure from this ideal structure. These include defects in the packing of the parallel layers, which have been demonstrated in a variety of crystallographic studies, and defects in the macro-aromatic network which constitutes any one layer. It has long been realized that any one such aromatic macromolecule must stop somewhere. At outside edges, the carbon atoms of macro-aromatic molecules probably form organic derivatives such as C═O, C—OH, —C—H, in order to satisfy valency requirements. Some of these outside edge atoms may also form weak C—C bonds of the hexaphenyl–ethane type between pairs. Interesting new types of crystal defect are also possible at carbon atoms situated at internal points of any macro-aromatic network, whenever such atoms are not joined to two carbon neighbours as in the planes of ideal graphite.

If such defect sites are completely closed in by macro-aromatic network, 'aromatic holes' are formed. Two examples are illustrated in Fig. 1, but there are many others. If they are situated at re-entrant portions of the network which are not closed, 'claw defects' are formed. One type is illustrated in Fig. 2; many variants can be constructed. The object of this communication is to direct attention to some properties of the carbon atoms at edges of internal holes or claws which throw some light on observations in actual crystals of graphite.

Suppose one of the carbon atoms C_a marked *a* in Fig. 1 at an internal edge defect forms a chemical bond, such as —C—H or C—OH; it may even form C═O with appropriate readjustments of other C—C bonds in the neighbourhood. Such bond formation immediately affects the possibilities of satisfying the valency requirements of carbon atoms at neighbouring sites in the hexagonal network, marked *b* in the diagram.

One possibility is that C_b atoms also form chemical bonds, just as they would at external free edges of the macro-molecule. As a consequence, the network must bulge around the 'hole' or 'claw', owing to the repulsions between the groups bonded to C_a and C_b. 'Claw' buckling of molecules which would normally be planar has been established by optical activity and X-ray methods[1] in smaller aromatic molecules.

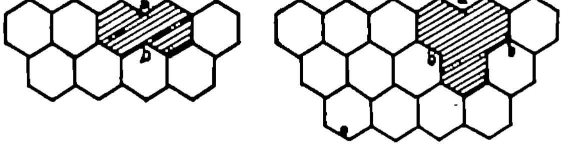

Fig. 1. Naphthalene 'hole'

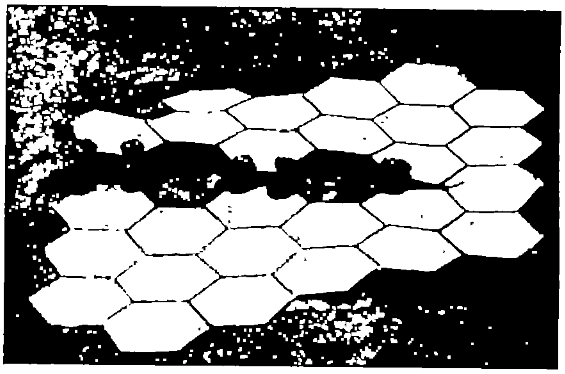

Fig. 2

There is some evidence[2] that this out-of-plane buckling and distortion must extend over several carbon atoms around the 'hole' or the internal tip of the 'claw'. In any carbon macro-molecule that would constitute a layer in ideal graphite, out-of-plane buckling starts at a claw defect and can lead to far-ranging out-of-plane co-operative defects. In building a claw macro-molecule, the structure with lowest energy is that which balances repulsion energy between foreign atoms joined to C_a, C_b, against the loss of resonance energy resulting from the out-of-plane configurations of the fused carbon rings. Various types of claw formation can be envisaged to satisfy this condition. These need not be detailed here, but it is useful to note that the consequences of a single claw defect in a macro-aromatic network has a bearing on catalytic influences in the chemical reactivity of solid carbon.

Alternative to the formation of chemical bonds at C_a, C_b, with consequent buckling of the macro-aromatic network, a second possibility is that the planar configuration is conserved, despite the defect. This could happen, for example, at an 'aromatic hole' in one macro-aromatic layer, firmly sandwiched between perfect macro-aromatic layers above and below it, at approximately the normal *c* spacing of 3·54 A. At such defect sites, C_a can still form a chemical bond with a foreign atom such as —C—H, leaving C_b vacant as a 'trapped unpaired spin'. Because of the compensating effect of repulsion energy in the crystal and the energy of spin pairing, the arrangement

$$\left\{\begin{array}{l}C_a \text{ combined with a foreign atom}\\ C_b \text{ spin unpaired, one electron deficit}\end{array}\right.$$

can have a lower potential energy than

$$\left\{\begin{array}{l}C_a \text{ combined with a foreign atom}\\ C_b \text{ combined with a foreign atom}\end{array}\right.$$

as discussed in the first possibility. In this case, the hole (or, though less likely, the claw) can provide a mechanism for the trapping of unpaired spins. This could have a bearing on the interesting observation[3] on unpaired electron spins which are observed in partly ordered graphite, as disordered carbon is progressively heated.

Sources of Radio Noise on the Planet Jupiter

The discovery in 1955 by Burke and Franklin[1] of a source of radio noise corresponding to the position of the planet Jupiter was confirmed by Shain[2], who reviewed a series of old records taken in an investigation of cosmic noise at 18·3 Mc./s. during 1950–51. Shain found that certain noise bursts, which previously had been assumed to be interference, corresponded to the times when Jupiter was passing through the reception beam of the aerial system. He then expressed the times at which these noise bursts occurred in terms of the System I and System II zenocentric longitudes used for Jupiter (corresponding respectively to rotation periods of 9h. 50m. 30s. in the equatorial belt and 9h. 55m. 40·6s. for the rest of the planet) and found that a certain periodicity was shown in the System II longitudes, corresponding to a localized source at a longitude of 67°. The results were correlated, so far as possible, with visual observations made by the Jupiter Section of the British Astronomical Association, and the possible identification of the noise source with a visual disturbance in the Southern Temperate Belt was discussed.

A further investigation of the Jupiter radio noise has been made in this laboratory at 18·0 Mc./s., using an eight-dipole aerial array having a beam width, to the half-power points, of about 30° in the east–west direction. A series of daily records were taken from December 31, 1956, to March 8, 1957; nearly every record was taken in the presence of an observer to guard against recording unwanted interference. It was found that the noise bursts occurred less frequently than when observed by Shain during 1950–51; a total of sixty-seven observations yielded thirty-seven useful records on which the radiation appeared with a good degree of certainty.

Following Shain, the times when the noise bursts occurred were expressed in longitudes of the central meridian during the bursts, and these are shown for System II in Fig. 1. Histograms were made of the frequency of occurrence of the noise for 5-deg. intervals of central meridian longitude, and these are shown in Fig. 2. In System I the distribution appears to be random, but in System II the noise bursts occur most frequently in two longitude bands centred on about 105° and 210°, each band having a maximum width of about 90°. This suggests the existence of two sources of noise, with the possibility of a somewhat weaker source centred on about 290°, near the present longitude of the Red Spot.

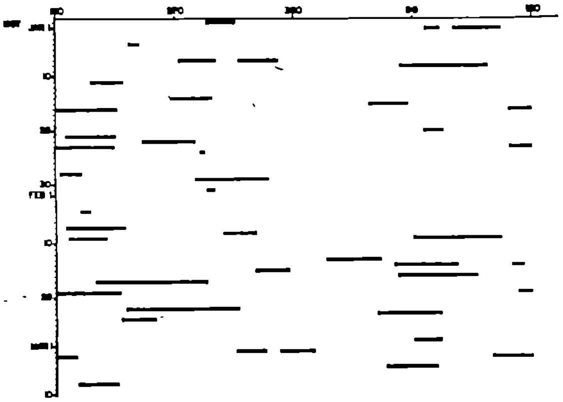

Fig. 1. Observed periods of noise in terms of System II zenocentric longitude

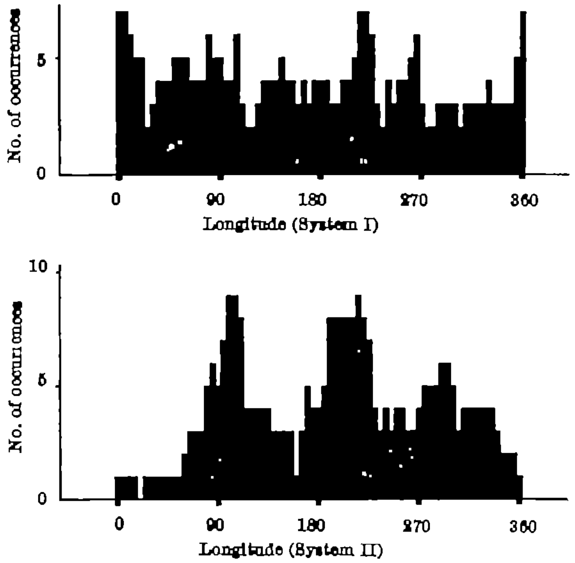

Fig. 2. Histograms showing frequency of occurrence of the noise bursts for 5-deg. intervals of central meridian longitude in both System I and System II

A final correlation of the radio observations with possible visual features is awaiting reports from the British Astronomical Association and the Association of Lunar and Planetary Observers on the current apparition of Jupiter. It would seem likely from both Shain's and our observations that any radio noise which has been observed so far is due to a localized source, or sources, and is not distributed over the whole body of the planet.

The narrow longitude band-widths of the two sources indicated in Fig. 2 suggest the existence of an ionosphere on Jupiter, since the longitude band-widths should be at least 180° if no refraction effects occur. If a localized source is assumed and the critical angle is taken as 45° (half the longitude band-width), then an electron density of the order of 10^6/cm.^{3} is indicated, which is comparable to that of the Earth.

Shain's source was found to have a longitude band-width of about 135°; this could have been due to two overlapping sources, possibly the same two sources observed by us, drifts in longitude having taken place to separate the sources and to change the longitudes of their centres.

It is hoped to publish a more detailed account of this work elsewhere. One of us (C. H. B.) is studying in the United States under the Fulbright Programme sponsored by the Institute of International Education.

Short Time Transients in Solar Noise

At the radio observatory near Dwingeloo, a beginning has been made with measurements of solar radiation at 400 Mc./s. The aim is to obtain quantitative data about transients of short duration (pips), and possibly some insight into the underlying mechanism which excites the coronal plasma. Some parameters in question are: length of the time interval between half-power points (duration), intensity, asymmetry, frequency band-width and polarization-rate.

The principal result of preliminary measurements on a dozen days, spread over three months, concerns the duration of pips. A histogram on 500 isolated and fairly isolated ones yields a sharp maximum at 0·18–0·03 sec. Other values occur much less frequently, and there is no indication of a second maximum of less than 1 sec. No correlation has been found between duration and height of pips.

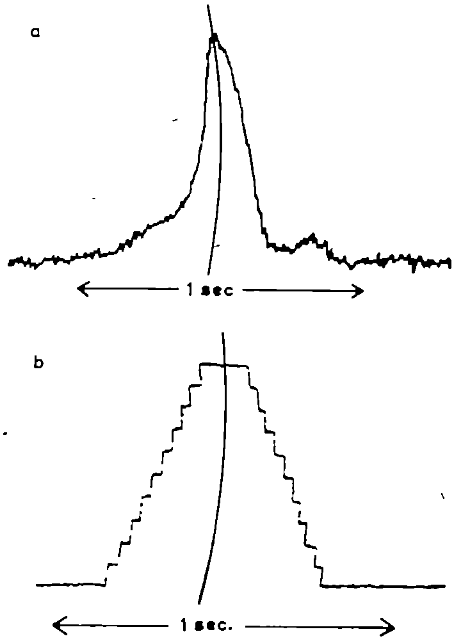

Fig. 1. (*a*) Record of a typical pip. (*b*) Record of a step voltage illustrating resolving power in time of recorder

Perhaps the time interval between successive pips is a relevant quantity during noise storms. Such a period on August 29, 1956, yielded 0·25 ± 0·04 sec.; the mean duration was 0·13 ± 0·03 sec.

The fact that these values come out with a rather low spread suggests that they are related to an elementary phenomenon, amenable to theoretical description. Reber[1] has put forward a hypothesis, which claims the existence of a linear relationship between wave-length in metres and duration of pips in seconds, the constant of proportionality being one. Apparently this does not hold when the wave-length is 0·75 m.

An accuracy of 0·01 sec. being readily obtainable, it seems to be worth while to determine mean durations on several wave-lengths and their dependence on time.

Thanks are due to the Radio Astronomy Section of the Netherlands PTT (Postal Service) for lending the receiver. The work has been supported financially by the Netherlands Organization for Pure Scientific Research (ZWO).

Determination of Radon and Thoron in Air

The presence of natural radioactive gases in the atmosphere was first demonstrated more than fifty years ago, and in recent years interest has been renewed in the subject.

A method for determination of radon favoured by the later investigators has been filtration of about 1 cubic metre of air, and subsequent detection of the activity found on the filter using a particle counter or ionization chamber; radon passes through the filter and the short-lived activity observed is that of the four immediate daughter products attached to dust particles. With appropriately large volumes of air, a similar procedure is suitable for the determination of thoron products, the activity of which still remains when, after the lapse of a few hours, radon products are virtually decayed. Activity remaining after a few days is attributable to fission dust.

Published figures of natural radioactivity show some differences which are difficult to reconcile, and, in so far as investigators have been reticent in indicating their methods of calculation, it is uncertain whether satisfactory formulation has always been achieved of the equations which express the complex pattern of decay. The purpose of this communication is to put forward general expressions by which the concentration of radioactive gas may be related to the observed activity of mixed decay products in the filtration type of experiment. These expressions are a corollary of Rutherford's mathematical theory of successive changes and they are found to reduce to a simple symmetrical form.

The decay constant (λ) for each radioactive species is commonly employed in such calculations, but in the present instance there is a notational advantage in using the reciprocal of λ. This constant, denoted here as Λ, can be defined as the time in which a large number of atoms of an isolated species decays to the fraction $1/e$; Λ also represents the mean life of the atoms.

Consider the case in which air is filtered at a constant rate from an atmosphere in which the concentration of radon remains constant, the decay products being in secular equilibrium. Let Λ_A be the mean life of radium A expressed in minutes, and Λ_B, Λ_C, $\Lambda_{C'}$, the corresponding constants for radium B, C and C′. T is the period of filtration in minutes, and t any time in minutes subsequent to T. For typographical convenience:

$$A = 1-\exp(-T/\Lambda_A)\,; \quad B = 1-\exp(-T/\Lambda_B)\,;$$

$$C = 1-\exp(-T/\Lambda_C)\,; \quad \text{etc.}$$

$$a = \exp(-t_1/\Lambda_A) - \exp(-t_2/\Lambda_A)\,;$$
$$b = \exp(-t_1/\Lambda_B) - \exp(-t_2/\Lambda_B)\,; \quad \text{etc.}$$

It can be shown that the expressions which follow are a measure of the number of particles of each type emitted from the filtered material in an interval $t_2 - t_1$:

Radium A (α) : $\Lambda_A{}^2 Aa$

Radium B (β) : $\dfrac{\Lambda_A{}^3 Aa}{\Lambda_A - \Lambda_B} + \dfrac{\Lambda_B{}^3 Bb}{\Lambda_B - \Lambda_A}$

Radium C (β) : $\dfrac{\Lambda_A{}^4 Aa}{(\Lambda_A - \Lambda_B)(\Lambda_A - \Lambda_C)} +$

$$\frac{\Lambda_B{}^4 Bb}{(\Lambda_B - \Lambda_A)(\Lambda_B - \Lambda_C)} + \frac{\Lambda_C{}^4 Cc}{(\Lambda_C - \Lambda_A)(\Lambda_C - \Lambda_B)}$$

Radium C′ (α) : $\dfrac{\Lambda_A{}^5 Aa}{(\Lambda_A - \Lambda_B)(\Lambda_A - \Lambda_C)(\Lambda_A - \Lambda_{C'})} +$

three symmetrical terms

Substituting specific values for Λ, the expressions reduce to :

Radium A (α) : $19{\cdot}4\ Aa$

Radium B (β) : $-2{\cdot}5\ Aa + 1{,}687\ Bb$

Radium C (β) : $0{\cdot}5\ Aa + 6{,}367\ Bb - 2{,}652\ Cc$

Radium C′ (α) is virtually the same as radium C since $\Lambda_{C'}$ is very small.

After evaluating for particular time periods, each line is multiplied by a factor representing the efficiency of detection of the respective particle, and also by a factor $2{\cdot}22\ vx$, where air has been filtered at v litres per minute and x is the unknown concentration of radon in micro-micro curie per litre. The solution of x is then obtained by equating to the observed 'count'.

If an initial state of equilibrium does not exist within acceptable limits, air to be sampled should be isolated, and filtered after waiting for a period sufficiently long for transient equilibrium to be established. The expressions appropriate to this case also reduce to symmetrical form. Let Λ_O be the mean life of radon, and P the waiting period. The following examples illustrate the manner in which the expressions are modified, that is, by a common factor in each line, and a conditional factor in each denominator.

Radium A (α) : $\Lambda_O \exp\left(-\dfrac{P}{\Lambda_O}\right) \cdot \dfrac{\Lambda_A{}^2 Aa}{\Lambda_O - \Lambda_A}$

Radium C (β) :

$$\Lambda_O \exp\left(-\frac{P}{\Lambda_O}\right) \left[\frac{\Lambda_A{}^4 Aa}{(\Lambda_O - \Lambda_A)(\Lambda_A - \Lambda_B)(\Lambda_A - \Lambda_C)} + \frac{\Lambda_B{}^4 Bb}{(\Lambda_O - \Lambda_B)(\Lambda_B - \Lambda_A)(\Lambda_B - \Lambda_C)} + \frac{\Lambda_C{}^4 Cc}{(\Lambda_O - \Lambda_C)(\Lambda_C - \Lambda_A)(\Lambda^C - \Lambda_B)}\right]$$

Expressions appropriate to thoron can be formulated on similar lines, and because of the long life of the component thorium B, it is possible to determine thoron in the presence of relatively large concentrations of radon. Actinon and its daughter products have mean lives which make specific detection in the atmosphere almost impracticable in the presence of radon.

Sites of the Incorporation of an Amino-acid into Proteins of *Bacillus megaterium*

WHEN the digestion of *B. megaterium* is carried out with lysozyme in suitable media of high osmotic pressure, the rod-shaped cells are converted into from one to four spherical protoplasts[1]. It has been shown by McQuillen that these protoplasts are capable of growing and dividing, and of effecting the synthesis of protein, nucleic acids, and adaptive enzymes[2]. If the medium in which the protoplasts are suspended is diluted, the cytoplasmic membranes surrounding the protoplasts burst and much of the cytoplasmic constituents is liberated into the medium[1]. This liberated cytoplasm contains no particles equivalent to the mammalian microsomes, ultracentrifugal analysis having shown that not more than 10 per cent of the material has a maximum molecular weight of 200,000, the residue being of much lower molecular weight. The bulk of the deoxyribonucleic acid of the cell remains associated with the 'ghost' cytoplasmic membranes and may be sedimented with them at low speeds on a bench centrifuge.

The whole protoplasts appeared to offer a suitable system for the study of protein synthesis in short time-intervals as it is possible to stop the process by pouring on to ice, thereby simultaneously cooling and bursting the cells with the consequent disruption of the cellular structure. Protoplasts were prepared from whole cells by aerobic incubation at 30° with lysozyme (0·2 mgm./ml.) in a glucose/ammonia/salts medium containing 0·5 *M* sodium citrate and 1 per cent casein digest. When the conversion was complete, the protoplasts were harvested and resuspended in an inorganic salts medium containing 1 per cent glucose and 0·5 *M* potassium dihydrogen phosphate. After aerobic incubation for a further 1 hr.

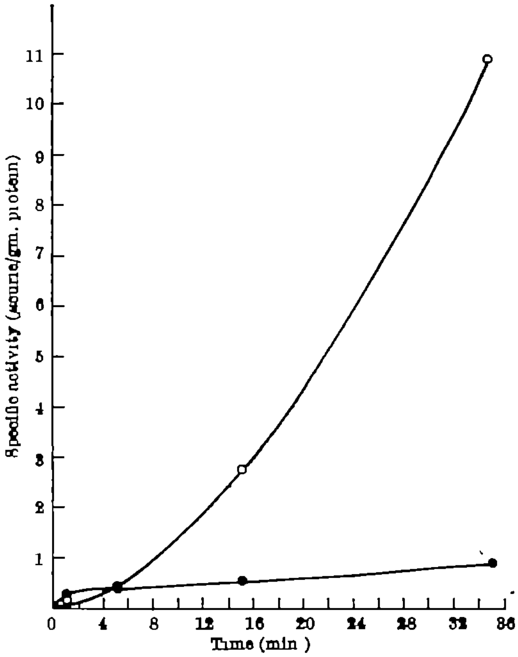

Fig. 1. Incorporation of [1-^{14}C]-glycine into the protein of cytoplasmic and membrane fractions derived from protoplasts of *B. megaterium*. The protoplasts (1 mgm./ml.) were incubated aerobically at 30° in an inorganic salts medium (pH 7·0) containing 0·5 *M* potassium dihydrogen phosphate and also 1 per cent glucose. After incubation for 40 min., [1-^{14}C]-glycine (0·2 μc./ml.) was added, and sampling carried out at various times as indicated in the text. ●, Membrane ; ○, cytoplasm

[1-^{14}C]-glycine was introduced, the incubation continued, and samples removed and poured on to ice after various intervals. The membrane fraction from the burst cells was sedimented and the protein precipitated with trichloroacetic acid from the sediments and from the supernatant cytoplasmic fraction. Lipids and nucleic acids were removed by the usual washing procedures, and the radioactivity of the acetone-dried protein fraction was measured. The results (see Fig. 1) show that in short periods of incubation the membrane fraction incorporates radioactivity to a greater extent, though afterwards the cytoplasmic fraction becomes more highly labelled.

The difficulty of preparing large quantities of protoplasts capable always of incorporating the amino-acids into protein at measurable rates caused us to consider a modification of the above procedure. It was then found that similar results could be obtained by reversing the order of the incorporation and lysozyme digestion stages. In this case whole cells were incubated aerobically in the usual growth medium (glucose/ammonia/salts, pH 7), to which the radioactive amino-acid was added and samples taken as before. After sedimentation, the chilled whole cells were resuspended in water and lysozyme added to digest the cell wall at 0°. In this way lysozyme and the less radioactive cell wall 'proteins' did reduce somewhat the radioactivity observed in the cytoplasmic fraction, but the results were qualitatively similar to those observed with protoplasts.

The deoxyribonucleic acid of the membrane fraction may be associated with some of the small spherical granules that can be seen attached to the surfaces of the cytoplasmic membranes after disruption by osmotic shock. We have found that treatment at 30° for 60 min. with 1 per cent aqueous sodium ethylenediamine tetra-acetate (pH 7) digests these bodies, at the same time solubilizing the deoxyribonucleic acid and some of the protein. Tracer studies were then performed as before with whole cells, but with the addition of this further fractionation procedure. The proteins from the resulting three fractions (membrane, cytoplasm, and 'deoxyribonucleic acid-protein') were then assayed, the results being shown in Fig. 2.

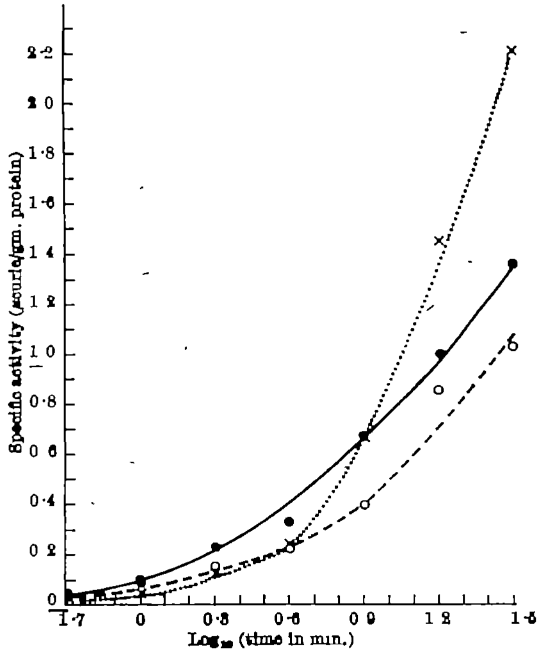

Fig. 2. Incorporation of [1-^{14}C]-glycine into the proteins of cellular fractions derived from whole cells of *B. megaterium*. The cells (5 mgm./ml.) were incubated aerobically in an inorganic salts medium (pH 7·0) containing 1 per cent glucose, and sampling was carried out as described in the text after the addition of [1-^{14}C]-glycine (0·05 μc./ml.). ●, Membrane; ×, cytoplasm; ○, 'deoxyribonucleic acid-protein'

These results therefore show that the initial observable incorporation of [1-^{14}C]-glycine into proteins occurs in this case in the cytoplasmic membrane. On the other hand, the protein associated with the deoxyribonucleic acid has the lowest specific radioactivity of the three fractions at all but the shortest periods of incubation, and even then is below the level found in the membrane fractions.

We thank Dr. K. V. Shooter for the ultracentrifugal analysis referred to, and Mr. R. Goodsall for his skilled technical assistance.

A Rapid Procedure for the Separation of Amino-Acids on Paper Chromatograms

IN this laboratory the technique of circular paper chromatography has been modified in that small rectangular strips of filter paper are used rather than filter paper disks. This has resulted in the separation of compounds as round compact spots rather than circular bands. In addition, a combination of a horizontal solvent flow with an increase in developing temperature has resulted in a rapid increase in the mobility of the developing solvent coupled with a desirable increase in resolution.

This horizontal solvent development technique at an elevated temperature has been applied to the following analyses: (*a*) Separation of lactose from the galactosyl oligosaccharides present in lactase-hydrolysed lactose preparations in 4 hr.[1] as compared to 20–24 hr. using a conventional descending technique. (*b*) Separation of galactose and glucose (as a unit) from lactose in 2 hr.[1] as compared to 16–18 hr. using a conventional descending technique. (*c*) Separation of acetic, propionic, butyric, valeric, and caproic acids in 1 hr.[2] as compared to 20 hr. using a conventional descending technique.

The success of these rapid separations has prompted further study on the application of horizontal paper chromatography at an elevated temperature to decrease the separation time of those compounds of interest in dairy research which are separated by paper chromatography. The present communication

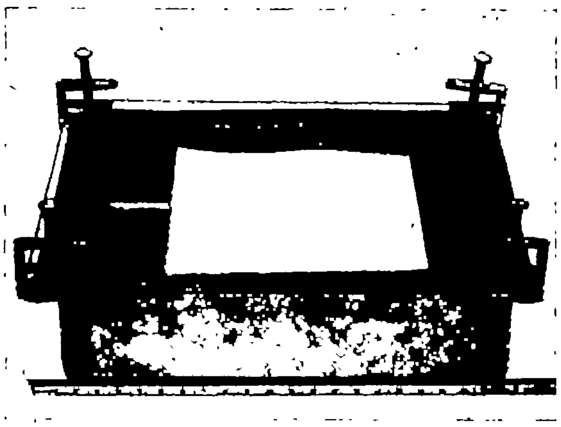

Fig. 1. The complete horizontal paper chromatographic chamber assembly in operation

presents the initial results of a study designed to develop a rapid procedure for the separation of twenty common amino-acids.

Whatman No. 1 filter paper, 12 cm. × 17 cm., is used. The origin is 2·5 cm. from one end. A 1·5-cm. tab, folded at a right angle to the paper, is inserted into the solvent trough. The opposite end of the paper is serrated using pinking shears, and a 1·0-cm. tab is folded at a right angle to the paper to permit the easy flow of solvent off the paper strip.

The chromatographic chamber measures 6 in. wide, 8 in. long, and 2 in. deep and is shown in Fig. 1. The chamber is fabricated from one piece of stainless steel, the pattern cut, and the four edges welded to form a rectangular chamber having a ½-in. flange all around.

A stainless steel solvent trough made from one-inch diameter tubing is held in place by two brackets spot welded to each side of the chamber. The filter paper is supported in a horizontal position by means of glass rods which in turn are supported by brackets spot welded to each side of the chamber. The brackets have notches for spacing the glass rods ½ in. apart. A sponge-rubber gasket is cemented to the flange and a glass plate cover is clamped to the flange in order to keep the chamber air-tight.

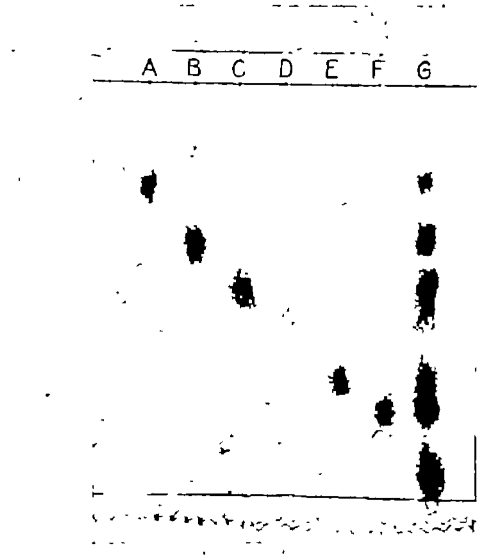

Fig. 2. Photocopy of a chromatogram after two successive 60-min. developments at 60° C. in the solvent system phenol buffered at pH 12·0: *A*, aspartic acid; *B*, glutamic acid; *C*, serine, *D*, glycine; *E*, threonine; *F*, alanine; *G*, mixture of twenty common amino-acids

Two solvent developments, each of 60 min. duration, at 60° C. using phenol buffered at pH 12·0[2] separate aspartic acid, glutamic acid, serine, glycine, threonine, and alanine from a mixture containing twenty common amino-acids (Fig. 2). The same separation using a descending procedure[3] requires a solvent development of 24 hr.

The amino-acid solutions containing 0·3 mgm./ml. of amino nitrogen per amino-acid (adjusted to pH 6·5) are applied to the filter paper (buffered at pH 12·0) in 0·5-microlitre volumes. The strip is then placed in the chamber which is in a 60° C. oven, the 1·5-cm. tab is inserted into the solvent trough, and solvent development occurs at 60° C. A portion of the developing solvent is also placed in the bottom of the chamber so that the atmosphere of the chamber becomes saturated with the vapours of the developing solvent.

Following the final solvent development, the chromatogram is dried for 30 min. at 60° C. in a mechanical convection oven, dipped in water-saturated butanol containing 0·4 per cent ninhydrin plus 4 per cent acetic acid, and the colour is developed[3] by placing the chromatogram in an oven at 60° C. for 15 min.

Cystine can be separated in 3 hr. using unbuffered Whatman No. 1 filter paper and butanol/acetic acid/water (25 : 6 : 25) at 60° C. (ref. 4).

In these separations it is not necessary to prepare the solvent systems at the developing temperature. The solvents were prepared at 22° C. in a temperature-controlled room prior to their use at the higher temperature.

A Convenient Method for labelling biologically interesting Carboxylic Acids with Tritium

ORGANIC molecules tagged with tritium are used more and more frequently in biology and medicine, especially for the exploration of metabolic pathways. In this respect, tritiated carboxylic acids are particularly useful tools for the study of various biochemical processes, such as the dehydrogenation and oxidative degradation of higher fatty acids, and determination of the sites of such reactions.

Hitherto, the preparation of tritiated compounds involved either complicated techniques or, more recently, random exchange reactions with gaseous tritium[1]; the latter procedure, however convenient, cannot be used when molecules tagged in specific positions are required. A new method is now described, by means of which a large number of carboxylic acids labelled with tritium in several definite positions can be very easily prepared, in good yields and with high specific activities.

The reaction used was the reductive desulphurization of carboxylic acids of the thiophen group by means of the Raney nickel–aluminium alloy in tritiated water, the experimental procedure being the same as for ordinary hydrogenolyses[2] except that the alkali used was obtained by dissolving sodium oxide in tritiated water. The variety of labelled molecules thus obtained is demonstrated by the following examples:

Valeric acid labelled with six atoms of tritium at the α, β, γ, and δ positions (II) was obtained from 2-thenoic acid (I):

(I)

$CHT_2—(CHT)_2—CT_2—CO_2H$

(II)

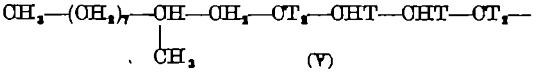
Caproic acid labelled with six tritium atoms at the β, γ, δ, and ω positions was similarly obtained from 2-thienylacetic acid; stearic acid labelled at the biologically important 9, 10, 11, and 12 positions (IV), which are the sites of possible biological dehydrogenation to oleic and linoleic acid, was prepared by hydrogenolysis of the appropriate thiophen acid (III):

(III)

$CH_3—(CH_2)_5—CT_2—CHT—CHT—CT_2—(CH_2)_7—CO_2H$

(IV)

Tritium-labelled tuberculostearic acid (V) could likewise be prepared, for use in autohistoradiographic studies[3]:



$CH_3—(CH_2)_7—CH(CH_3)—CH_2—CT_2—CHT—CHT—CT_2—(CH_2)_3—CO_2H$

(V)

$CHT_2—(CHT)_2—CT_2—(CHT)_2—CO_2H$

(VI)

Molecules labelled with eight tritium atoms were obtained by tritiolysis of the appropriate thiophen compounds such as β-(2-thienyl)acrylic acid, which gave oenanthoic acid (VI) labelled at all the available carbon atoms. Dicarboxylic acids could be labelled in similar manner, starting from the appropriate thiophen dicarboxylic acids[4].

Since Raney alloy desulphurizations can be applied to a wide range of organic compounds, substances having other chemical functions (alcohols, lactones, amines, amino-acids, etc.) are also susceptible to this method of labelling.

Internal Structure of the Virus-like Particles associated with the Rous Sarcoma, and their Presence in other Neoplastic and Normal Chicken Tissues

In ultra-thin sections of two out of three Rous sarcomas, Gaylord[1] found virus-like particles of spherical shape with a diameter varying from 45 to 60 mμ. They were characterized by a dense central core measuring about a third to a half the diameter and by a single outer membrane. These elements were mostly either isolated or in clusters outside the cells, clinging to the surface of the cell membrane; less frequently they were found in small vesicles within the cytoplasm. These observations have recently been confirmed on a larger scale comprising fifty-four Rous sarcomas grown on young chicks and twenty-one tumours grown on the chorioallantoic membrane[2]. In 41 cases of the first (76 per cent) and in 13 (62 per cent) of the second group, variable numbers of such particles were found, mostly extracellularly but also within the cytoplasm. Their size, however, was found to vary between 60 and 80 mμ. Further details concerning these findings and the reasons why they are believed to be the causative agent of the Rous sarcoma are discussed elsewhere[2].

The facts to be emphasized here are on one hand their finer structure revealed in high-resolution electron micrographs, and on the other, their occurrence in various other chicken tissues. Upon close examination, it was found that they have not one but two distinct membranes (Fig. 1): an outer one which surrounds the particle and an inner one enclosing an apparently transparent zone around a dense central core. This 'nucleoid' measures between 30 and 40 mμ (Fig. 2). The existence of two membranes might appear a minor detail at first. The importance of such an ultrastructure, however, lies in the fact that it puts the particles in line with known virus bodies of a somewhat similar ultrastructure which corresponds to a definite phase of their evolution.

By analogy with the Bittner virus, where the outer viral membrane is formed by a very small portion of the cell membrane at the moment when the virus body segregates itself from the cell from which it originates[3], one might assume that a comparable mechanism exists here. This view would give a morphological basis for a theoretical concept reached as a conclusion to all the complicated and conflicting data concerning Rous sarcoma virus, which is the presence of two antigens (Harris[4], and Oberling and Guérin[5]). The host antigen may thus be located at the peripheral structure of the particle.

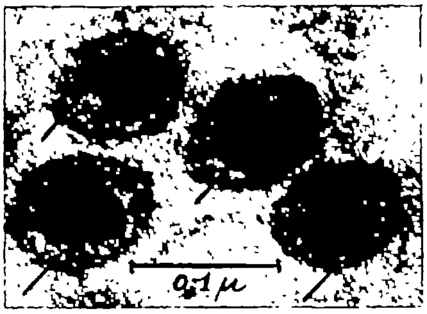

Fig. 1

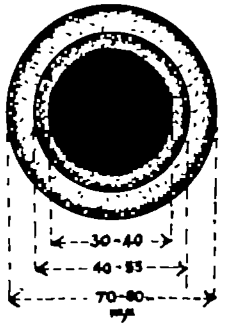

Fig. 2

The occurrence of these bodies in various amounts in other chicken neoplasms such as the Murray-Begg tumour[4], the erythroblastosis[7] and their presence even in normal young chickens[7] is an important fact, but for the moment its interpretation remains hypothetical: there may exist either an inactive ubiquitous agent in all chicken tissues which can become differentiated and oncogenic in an appropriate environment; or, the particles in normal controls could represent the widespread lymphomatosis virus, although the strains used for this study were clinically free of this disease.

Intestinal Lecithinase

Schmidt, Bessman and Thannhauser[1] described a phospholipase in mitochondria of rat intestinal mucosa which is highly active towards cephalin but relatively inactive towards lecithin. A possible explanation of this lack of activity towards lecithin was found in our studies of a similar enzyme preparation from rat intestine. It was found that the breakdown of lecithin to glycerophosphorylcholine depends on the concentration of enzyme used (see Fig. 1, (I)–(III)). With low enzyme concentrations a considerable lag period was observed followed by an autocatalytic rate of reaction. The lag period could be abolished by the addition of degradation products of lecithin, fatty acids (palmitic, oleic, stearic) and lysolecithin.

It seems likely that the presence of fatty acids is obligatory for lecithinolysis. Small amounts of fatty acids (6 μgm./ml.) were found to be present in the enzyme preparations. Lysolecithin also furnishes fatty acids due to the active lysolecithinase present. Similarly, the activation by cephalin reported by Schmidt *et al.*[1] may be due to the fatty acids liberated from this substrate.

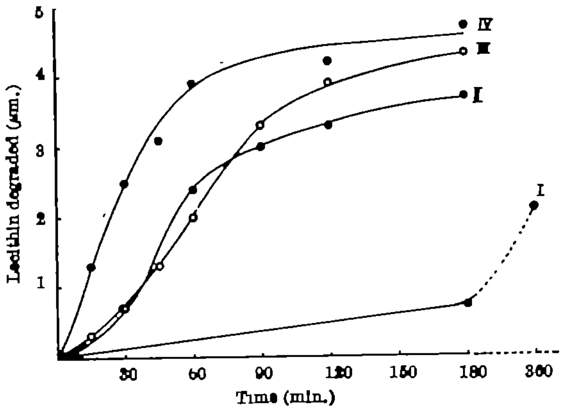

Fig. 1. (I) With 0·3 ml. enzyme; (II) with 0·3 ml. enzyme plus 4 μgm. palmitic acid; (III) with 0·6 ml. enzyme; (IV) with 0·6 ml. enzyme plus 4 μgm. palmitic acid.

Rat intestinal mucosa was ground with equal weight of sand, extracted with water (2 ml./gm. mucosa) and centrifuged at 600*g* at 4° C. The supernatant was brought to *p*H 5·5 with 0·1 *N* acetic acid and the precipitate was resuspended in 0·02 *M* phosphate buffer *p*H 6 (2 ml./gm. of original tissue weight). 5 μgm. egg lecithin (ref. 3)+40 μgm. phosphate buffer *p*H 6 with the indicated enzyme amounts made up to 1 ml. was incubated at 37° C. The rate of the reaction was determined by following the decrease in ester content according to Stern and Shapiro (ref. 4).

The intestinal lecithinase described differs from generally known lecithinases[2], being bound to particles and inhibited by Ca^{++} at 20 μgm./ml. and Cd^{++} 0·5 μgm./ml. as well as by cholic acid. Lecithinase activity could not be separated from lysolecithinase by any purification procedure so far tried.

Sensitivity of Pancreas Hexokinase towards Alloxan and its Modification by Glucose

The administration of glucose, mannose or fructose, but not galactose or several other sugars tested, can prevent the effect of a normally diabetogenic dose of alloxan. This protection was found by Bhattacharya[1,2] in the rat. From the relative efficiencies of these sugars he concluded that the diabetogenic action of alloxan could depend on an inactivation of the hexokinase of the beta cells of the pancreas. Arteta and co-workers have confirmed the protective effect of glucose in the dog[3]. They have also observed that insulin[3] and floridzin[4] can increase, and adrenalin[5] and glucagon[6] can decrease, the sensitivity towards alloxan, apparently in relation to their effect on the blood sugar-level. The work described here on the effect of alloxan on pancreas hexokinase *in vitro* does not support the hexokinase inhibition theory of alloxan action.

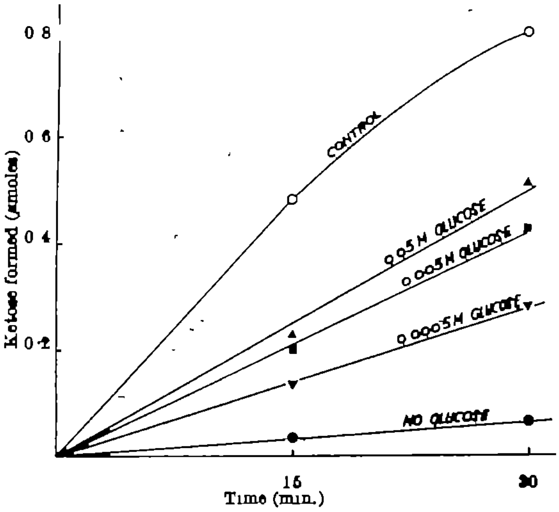

Fig. 1. Effect of the concentration of glucose on the protection of pancreas hexokinase against inactivation by alloxan. The buffered enzyme, with glucose at final concentrations as indicated, was incubated with 0 004 *M* alloxan (except the control) for 5 min. Residual hexokinase activity was then estimated by the total ketose formation method, carrying out incubations of 15 min. and 30 min. for each kind of pretreated sample

Experiments were carried out with a partially purified preparation of dog pancreas hexokinase (Villar-Palasí, C., unpublished work). Assay of hexokinase activity was carried out with glucose as substrate by the method of substrate disappearance[7] or the ketose ester formation method[8]. The latter was modified by the addition of a large excess of phosphoglucose isomerase and phosphofructokinase; total ketose was estimated on trichloroacetic acid filtrates by the cysteine–carbazol method[9]. The incubation mixtures were strongly buffered (0·2 *M* phosphate, *p*H 7·5) to prevent any marked changes when alloxan was added.

Incubation of the buffered enzyme with 0·004 *M* alloxan for 5 min. at 30° C. resulted in 93 per cent inactivation of the enzyme. Sensitivity of a hexokinase towards alloxan had been previously observed in muscle extracts[10]. In the presence of 0·005 *M* glucose the inactivation was only 58 per cent. With glucose at this concentration doses of 3, 2, 1 and 0·5 micromoles of alloxan per ml. produced inhibitions of 53, 40, 30 and 25 per cent respectively. Fig. 1 shows the effect of drastic changes in the concentration of glucose above and below that corresponding to the normal blood sugar value. It also illustrates the fact that five minutes after the addition of the alloxan the inactivation of hexokinase has levelled off. Since the K_m of the enzyme for glucose is 1×10^{-5} *M* (Villar-Palasí, C., unpublished work), the non-competitive partial prevention of alloxan inhibition by glucose may be interpreted as a result of the masking of the active centre by a substrate which thus hinders the inactivation by the —SH reagent.

The small differences in the degree of protection conferred by the different concentrations of glucose are out of proportion with the close relationship between blood glucose and sensitivity towards alloxan[3–6]. Moreover, Bhattacharya[2] has reported that the relative protective abilities are glucose : mannose : fructose = 100 : 50 : 15, "which closely simulate their relative affinities to the ordinary mammalian hexokinase". In fact no known animal hexokinase approaches such relationship[7]; and that of dog pancreas has relative affinities as different as 100 : 100 : 1 (Villar-Palasí, C., unpublished work).

Thus, although alloxan can inhibit the pancreas hexokinase, and glucose can afford some degree of protection, there appears to be no real basis for the hexokinase inhibition theory of the diabetogenic action of alloxan. We would rather point to the fact that glucose, mannose and fructose have in common something more than functioning as substrates for hexokinase: they are the only sugars that can be glycolysed by most animal tissues. Sensitivity towards alloxan might thus be related to the energy supply of the beta-cells. The differences observed in the efficiency of these three sugars *in vivo* may well be related to differences in their transport across the cell membrane.

Field Evidence of Density-governing Reaction in *Sminthurus viridis* (L.)

THE limits of distribution of the lucerne flea in Western Australia are determined primarily by rainfall and temperature[1]. Thus the infested area is restricted to a comparatively small section in the south-west corner of the State, where the occurrence of the active stages of the insect is determined primarily by favourable conditions of rainfall and temperature. In most places the high temperatures and low rainfall of the summer period cause the active stages to disappear completely, continuity of the species being maintained by the highly resistant aestivating eggs.

The population fluctuations caused by changes in temperature and rainfall can be easily observed and demonstrated[1,2]. However, when comparatively small areas are examined closely, local population variations are observed which bear no relation whatever to the prevailing moisture and temperature conditions.

In order to study these latter variations, an area ten chains square, mostly under *Medicago* and *Hordeum* spp., was selected in September 1952. Permanent sampling sites were established by placing pegs at the points of intersection of grid lines drawn over the area. After the hatching of the aestivating

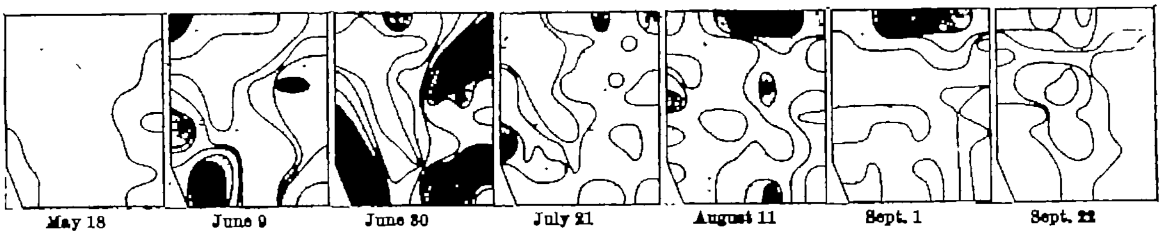

Fig. 1. Maps showing changes in distribution of *S. viridis* in observed area during 1953. Contour lines at 133 fleas per square link, except within unshaded areas where the line represents 66 fleas per square link. Darker shading indicates higher density

eggs in the autumn of 1953, population samples were collected every three weeks from the area within about five yards of each peg. The population density of *S. viridis* at each peg on each sampling date was thus obtained, and maps were drawn to show the pattern of numerical distribution at regular intervals throughout the season (Fig. 1).

The general inverse relation between the population density of lucerne fleas at any particular point at the beginning of the season and the density at the same point towards the end of the active season is shown clearly in these maps, and also in Fig. 2. Similar trends are shown by data obtained from the same area in subsequent years and from another study area in a distant locality.

Evidence has been gathered which shows that this changing mosaic of densities is not caused by mass movement of the lucerne fleas from areas of high to areas of low population density. The distances to be covered are too great and, at the most, some minor intermingling of the insects from neighbouring sampling sites may take place towards the end of the season. Therefore, the changes in the mosaic must be brought about by local differences in birth-rate or survival, or in both.

Examination of Fig. 2 shows that where densities exceeded approximately 20 per square link in May they had decreased by September, and where they were below this figure in May they had increased, there being only a few minor departures from this relation. Also, in general, the greater the departure from 20 in May, the greater was the departure, of opposite sign, in September. (This figure of 20 fleas per square link applies, of course, only to the data presented and may vary considerably according to the actual time of sampling and prevailing environmental conditions.) The coefficient of correlation between the estimated initial and final population densities of fleas was $-0 \cdot 426$ (significant at $P < 0 \cdot 001$). Statistically significant negative correlations were also obtained for the next three seasons (1954–56). This clear-cut and consistent relation between absolute density-levels strongly implies that the changes in density recorded at each observation point were due largely to some factor influenced by population density.

Preliminary field experiments have provided direct evidence of density-induced governing reaction, for they show that, in areas where the insect was abundant, fertility was reduced, and mortality was considerably increased. This is consistent with the laboratory experiments made with *S. viridis* by Maclagan[6]. It has not yet been determined whether these variations in fertility and mortality related to density are caused directly by interference between overcrowded individuals, or indirectly through the depletion of the environment or its impairment in other ways.

Currie[4] and Wallace[5] showed that the predatory bdellid mites (*Biscirus* spp.) had a pronounced influence on the numbers of the lucerne flea. Small numbers of a species of *Scirus* sp. occurred in the study area, but the distribution of this predator was at no time correlated with flea distribution, and later observations have shown that changes in lucerne flea numbers similar to those described above occur when the bdellid mite is eliminated by a selective insecticide.

It might be argued that small-scale variations in topography which could influence moisture, such as a mosaic of soil types or of ridges and hollows, might cause environmental favourability to decrease in some areas and to increase in others during the course of a season. Observations over four successive years, however, showed that the density mosaic patterns were very different each year, and so could not be related to any underlying topographical pattern. Also, if changes in environmental favourability were independent of density, the points in Fig. 2 would have been more or less randomly scattered. Furthermore, it is inconceivable that temporary local variations in weather conditions could have produced the observed changes in the density mosaic within such very small areas as those studied. The conclusion is inescapable that variations in the physical environment independent of density of population cannot be the cause of the inverse density relationship observed.

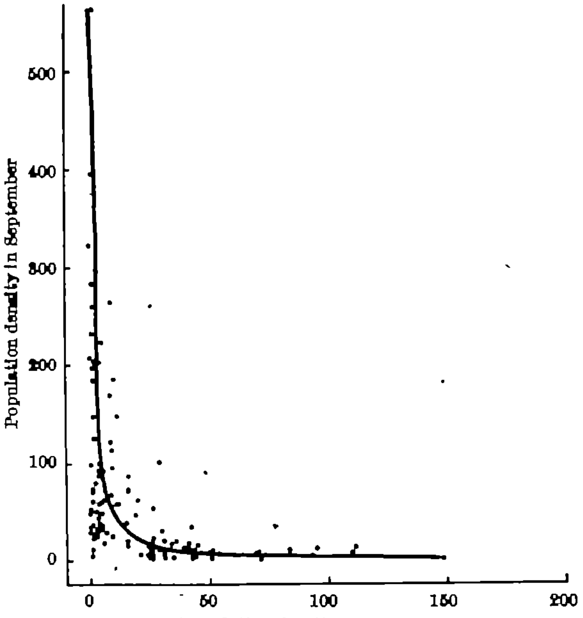

Fig. 2. Relation between density of *S. viridis* at given points early in the 1953 season and density at the same points later in the season

Thus there can be little doubt that, in the localities studied, the numbers of *S. viridis* were subject to tardy density-governing reaction[4], for high densities were observed to be followed within a few months by low densities, and vice versa. This is a mechanism which tends to keep populations fluctuating about an equilibrium level, which in turn varies in relation to changing environmental conditions[5].

Dwarf *Drosophila* produced by Ethylene Diamine Tetra-acetic Acid: a Relationship to Chelation of Zinc

Many chemical and physical treatments have been used for producing non-heritable changes in development. When such changes resemble known mutants, they are called phenocopies. A variety of phenocopies has been induced by metals or metal-inhibiting compounds[1].

In a strain of *Drosophila melanogaster*, dwarf or midget phenocopies were caused by a metal-complexing or chelating agent, ethylene diamine tetra-acetic acid (EDTA). The portions of a metal which are bound or free depend directly on the stability constant of that ion[2]. Hence, if a metal ion is added to food with ethylene diamine tetra-acetic acid, that metal, and metals with lower stability constants, will be released, while metals with higher stability constants will remain bound. In the dwarfing response reported here, cations were added one by one to determine the critical metal chelated by ethylene diamine tetra-acetic acid.

The food used for the *Drosophila* consisted of the following materials: 55 ml. each of corn syrup (Karo) and molasses, 22 gm. of dried brewer's yeast (Anheuser-Busch strain *G*), 88 gm. of corn meal, 22 gm. of oat meal, 11 gm. of agar, 2·7 gm. of methyl-parahydroxybenzoate (Tegosept *M*), 2·23 gm. of disodium ethylene diamine tetra-acetic acid (0·006 *M*) and distilled water to a final volume of 1 litre. Metals were added to the media at the molarities indicated in Table 1 and Fig. 1. All media for the growth of flies were autoclaved.

Table 1. Degree of Dwarfing when Divalent Metals were added to *Drosophila* Media with 0·006 *M* Ethylene Diamine Tetra-acetic Acid using the 3A Dwarf Stock

Molarity of metal ion	Percent of females +	Intermediate	Dwarf	Total females
No metal added	17·7	56·2	26·0*	192
0 005 Mg^{2+}	43·6	36·5	19·9	156
0 005 Ca^{2+}	8·2	61·2	30·6	49
0·005 Mn^{2+}	26·3	49·7	24·0	366
0 005 Fe^{2+}	52·1	34·2	13·7	73
0·005 Co^{2+}	100·0	0	0	416
0·005 Zn^{2+}	100·0	0	0	922
Control, no metal or EDTA added	99·8	0·2	0	478

* Means from different experiments average about 30 per cent ± 5

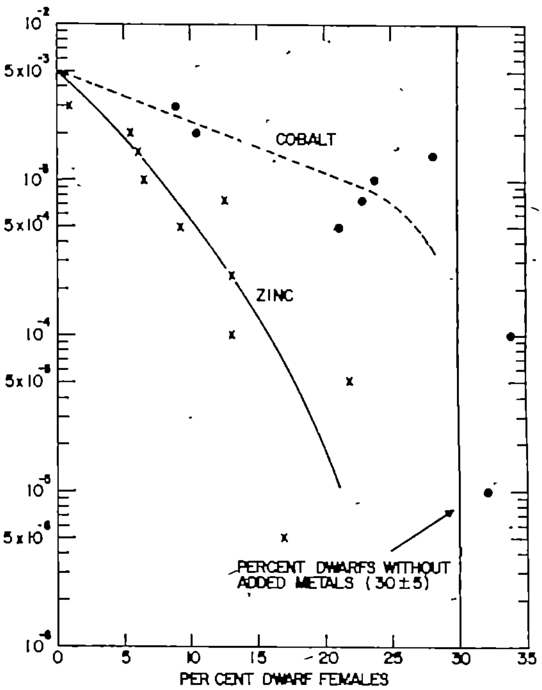

Fig. 1. Zinc or cobalt was added to *Drosophila* media containing 0 006 *M* ethylene diamine tetra-acetic acid

In the dwarfing experiments only females were scored. The length from head to wing tip was used as a criterion. The following classes were arbitrarily established using the maximum length of normally grown Oregon *R* as standard wild type. Dwarfs were a half to two-thirds the length of wild type, intermediates were longer than two-thirds but not exceeding three-quarters; and 'wild type' as used in Table 1 was longer than three-quarters. The *Drosophila melanogaster* stock, 3A dwarf, which was used originated from selected F_2 progeny of Oregon *R* wild type mated to a stock with the sex-linked genes yellow, cut, raspberry and forked.

When pairs of dwarfs were grown on standard food without ethylene diamine tetra-acetic acid they were usually fertile and had progeny indistinguishable in length from wild type. As seen in Table 1, dwarf females developed on the medium containing ethylene diamine tetra-acetic acid when no metals were added, or when divalent magnesium, calcium, manganous or ferrous ions were added separately. However, the addition of cobaltous or zinc ions completely prevented dwarfing.

Cobaltous and zinc ions have stability constants which are nearly the same ($Co^{2+} = 16 \cdot 10$ and $Zn^{2+} = 16 \cdot 15$)[3]. If competition for ethylene diamine tetra-acetic acid is to be demonstrated, ion concentrations lower than 0·005 *M* should be used. Theoretically, the dwarfing response of zinc and cobalt would then be distinguishable. As shown in Fig. 1, cobalt had no effect in preventing dwarfing at 1 × 10^{-4} *M* or less, while zinc at 5 × 10^{-6} *M* gave less dwarfing than the 30 ± 5 per cent value from ethylene diamine tetra-acetic acid media without metals added. Presumably, cobalt from 5 × 10^{-3} to 5 × 10^{-4} *M* could compete with zinc for ethylene diamine tetraacetic acid, leaving some zinc free. The prevention of dwarfing followed the metal series,

$$Mg^{2+} < Ca^{2+} < Mn^{2+} < Fe^{2+} < Co^{2+} < Zn^{2+}$$

The stability constants of these metals have the same order[3,4]. Zinc was apparently the critical metal bound by ethylene diamine tetra-acetic acid.

The period from hatching to pupation was lengthened by ethylene diamine tetra-acetic acid, and varied directly with concentration. A release of this growth inhibition was accomplished by adding metals. The degree of effectiveness was the same as above. With zinc there was no growth retardation. Other findings of these experiments, to be published elsewhere, were: (1) selective advantages for different genotypes; (2) changes of sex ratio in both directions; and (3) an autosomal inheritance for degrees of penetrance of the dwarf phenocopies.

Recently, ethylene diamine tetra-acetic acid has been used to increase the frequency of genetic recombination[5], and to enhance X-ray-induced chromosome breakage[6]. Some authors have assumed that ethylene diamine tetra-acetic acid chelated primarily calcium or magnesium. The *Drosophila* experiments presented here indicate that zinc, ferrous iron, manganese and other heavy metals are bound by ethylene diamine tetra-acetic acid before calcium and magnesium. Discussions concerning a mechanism for these effects on chromosomes should await further study.

Polymorphism in Human Trypanosomiasis

THERE are different theories about the significance of polymorphism in trypanosomes of the *brucei* group. According to Robertson[1], stumpy forms elongate into slender forms, which divide, giving rise again to stumpy forms. Fairbairn and Culwick[2] separated slender, intermediate and stumpy forms as three distinct entities, which they believed were produced by the sexual process of syngamy.

The present investigation was started in East Africa in 1955, using both a syringe-passaged and a fresh *T. rhodesiense* strain; in 1957 the work was continued in West Africa, using a cyclically transmitted strain of *T. gambiense*. It has been found that the number of trypanosomes in the blood of the mammalian host fluctuates more or less cyclically, and that the percentage of stumpy forms is lowest when parasitæmia is increasing and highest when it is decreasing. It was often impossible to differentiate between slender and intermediate and between intermediate and stumpy forms; such forms Hoare[3] refers to as transitional.

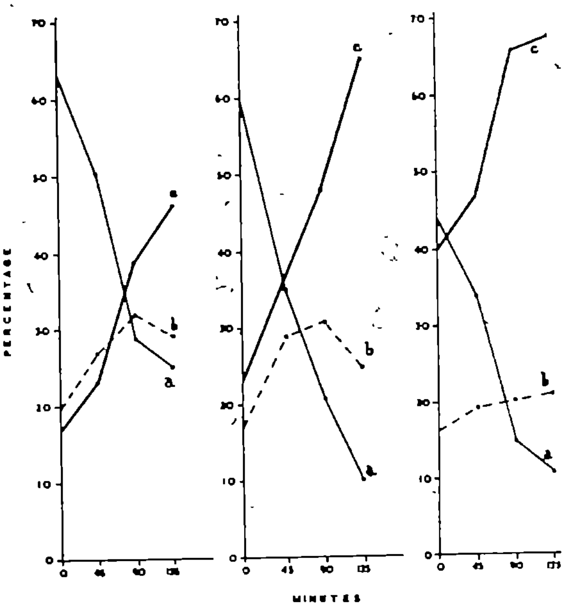

Fig. 1. (*a*), Slender forms; (*b*), intermediate forms; (*c*), stumpy forms

In the West African experiment with *T. gambiense* the white blood cells were also counted and differentiated. It was observed that a fall in parasitæmia was very often associated with a great increase in the lymphocytes in the blood.

From these observations it was concluded that the periodic decrease in parasitæmia is caused by the protective reactions of the host's body, and that the factor which causes this drop in trypanosome numbers is also responsible for the production of stumpy forms.

The common occurrence of transitional forms suggested that intermediate and stumpy forms are not produced by a sexual process between two slender forms, but by the shrinkage of the slender forms.

To investigate this last possibility, a *T. rhodesiense* strain was used which had been transmitted cyclically through rats since 1953. In order to obtain a fairly high percentage of slender forms, blood was taken during a rise in parasitæmia and 0·5 cm.^{3} was mixed with 1 cm.^{3} of human plasma and kept in a bottle at 37° C. At intervals of 45 min. the bottle was shaken, thin slides were made, the ratio of trypanosomes to erythrocytes was ascertained, and a morphological differentiation was made for 200 trypanosomes in each slide.

Observations were only valid for the first two hours of this experiment, because after that time the trypanosomes started to degenerate. Throughout the period of valid observation the number of erythrocytes remained approximately constant, as did the trypanosome–erythrocyte ratio, thus indicating that the number of trypanosomes did not decrease; however, the proportion of stumpy forms increased greatly at the expense of the slender forms, as will be seen from Fig. 1. Agglomeration, which could be described as syngamy, was practically never encountered until degeneration had started.

This experiment, therefore, makes it highly probable that stumpy forms are produced by the shrinkage of slender forms in circumstances in which the trypanosomes have to try to adapt themselves to an altering, or altered, environment.

A full report of this work will be given elsewhere. I am indebted to the Netherlands Organization for Pure Research (Z.W.O.) for a scholarship in 1955, to the Colonial Office for a Research Fellowship, and to Dr. K. C. Willett for his help and co-operation.

Chromosome Polymorphism in the Common Shrew

IN the autumn of 1955, Sharman[1] examined the chromosomes of five common shrews (*Sorex araneus* L.) from Buckland in Berkshire and one from the neighbourhood of Lake Vyrnwy in North Wales. He confirmed Bovey's[2] report that there are three sex chromosomes in the male, and made the surprising observation that the diploid number of chromosomes varied from 22 to 25 in different individuals. It appeared that some chromosomal elements could be present in either of two forms: as single V- or J-shaped (metacentric) chromosomes, or as pairs of rod-shaped (acrocentric) chromosomes, one rod corresponding to each arm of the V or J. The total number of autosome arms was therefore constant. This type of chromosome polymorphism is fairly well known in invertebrates, instances having been reported in several species of the Acrididae[3] and Coleoptera[4], in mantids[5], and in a mollusc[6]. A similar system may exist in the lizard, *Gerrhonotus scincicauda*[7], and in mammals an apparent case involving a single metacentric chromosome pair has recently been discovered in the rodent species *Gerbillus pyramidum* by Wahrmann and Zahavi[8].

In the summer of 1956, fifty more shrews were trapped, 44 of them on the grassy edges of a small thicket at Chilton, Berkshire, and the remainder less than a quarter of a mile away. Feulgen squash preparations of bone marrow and/or spleen and/or testis were made following pretreatment methods described elsewhere[9]. The results confirm and extend the findings of the previous autumn: the chromosome number was found to be constant within individuals but to vary from 22 to 27 in different males and from 22 to 25 in different females. The number of autosomal arms was constantly 36.

The chromosomes of two individuals are shown in Figs. 1 and 2, and diagrammatically in Fig. 3. Pairs of each of the normal autosomes (Nos. 1, 2, 3, 4, 5 and 9 in the diagram) were present in all the individuals examined. Apart from Nos. 3 and 4, which differ only slightly in size and have median centromeres, they are readily distinguished. The variable elements are Nos. 6, 7 and 8, each of which may be represented by a single metacentric chromosome or by two acrocentric chromosomes. J-shaped element 6 is easily identified. V-shaped elements 7 and 8 are not difficult to distinguish when both are present in the same cell (as in Fig. 1); but when one type alone is present photographs and measurements may be necessary for positive identification. Of the derivative rods, only that corresponding to the longer arm of metacentric element 6 can be identified with certainty. The interpretation here given is supported by the observation of the expected trivalent associations in stages from diplotene to metaphase in primary spermatocytes.

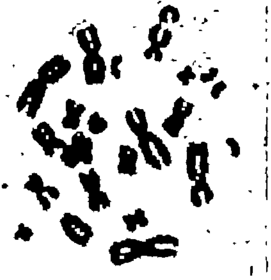

Fig. 1. Colchicine metaphase from spleen of shrew 35 (male). × 1,460

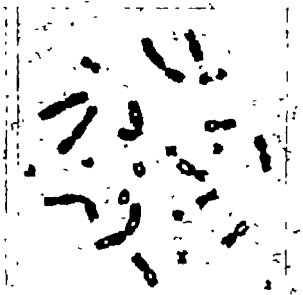

Fig. 2. Colchicine metaphase from spleen of shrew 39 (female). × 1,220

Each of the element pairs 6, 7 and 8 has now been observed (in different individuals) in three states, namely, as two metacentric, as one metacentric and two acrocentric, or as four acrocentric chromosomes. Theoretically, therefore, there should be $3^3 = 27$ cytological types possible. Fifteen of these have been identified.

Such a situation is formally equivalent to a polymorphic system with alternative genes at each of three loci, and comparison of the observed numbers of individuals of the different cytological types with those expected on the basis of the Hardy–Weinberg ratio is suggested. It was possible to define the chromosome set completely in 42 of the 50 individuals examined and these are classified and tested against expectation in Table 1. There is a small excess of heterozygotes for chromosome 6 and small deficiencies of heterozygotes for the other two chromosomes concerned, but the numbers are too small for a test of significance.

The common shrew is widely distributed in Europe and is evidently adapted to a diversity of ecological conditions[10]. At present we can only be certain that the polymorphic chromosome system we have de-

scribed exists within the county of Berkshire, since the Lake Vyrnwy specimen was a homozygote, and Bovey[2], the only previous authority, reported on two (Swiss) males only, both of which were evidently homozygotes. It may be assumed that the system is maintained because some of the cytological types have a selective advantage over others, but at present the details of this operation must remain largely conjectural. Significant deviation from the Hardy–Weinberg proportions might be in the direction either of an excess, or of a deficiency, of heterozygous types. An excess of heterozygotes could be attributed either to a direct selective advantage of the heterozygotes or to an assortative mating system favouring outbreeding. A deficiency of heterozygotes might be due to balanced advantages of the homozygous types or to inbreeding. Now the powers of dispersal of small mammals like the shrew are likely to be limited, so that a significant degree of inbreeding may well occur. Should this be combined with a selective advantage of heterozygotes, it would be possible for a situation to arise in which there was a spurious agreement with the Hardy–Weinberg ratio. It is therefore clear that a full analysis of the operation of the system of chromosome polymorphism in the shrew will not be possible without reliable information about the size and density of wild shrew populations and of the range of movement of single animals. Such information, combined with cytological study of samples of adults and of litters of embryos *in utero*, could help considerably towards an understanding of the genetical population structure of a common small mammal.

Significance of Vacuolated Neurones in the Medulla of Sheep affected with Scrapie

VACUOLATED neurones in the medulla have been considered for quite a long time by several workers as the only constant microscopic lesion in sheep affected with scrapie. On the other hand, Holman and Pattison[1], although finding vacuoles in all their clinical cases of scrapie, reported vacuoles in the medulla in a small proportion of non-scrapie sheep (in 5 out of 98 animals). Zlotnik and Rennie[2] examined material from 57 healthy sheep of various ages using serial sections from three levels of the medulla, and demonstrated vacuoles in about 73 per cent of sheep, mainly of the Cheviot breed. Bosanquet, Daniel and Parry[3] found only occasional vacuoles in the large neurones of the medulla of scrapied animals, but have seen similar vacuoles in normal sheep. Pattison[4] has discovered the incidence of vacuolated neurones in goats in which scrapie had been induced experimentally. According to him, 2,279 vacuoles were present in ninety-four sections, from medullas of 16 scrapie goats, whereas only 8 vacuoles could be found in 592 sections from medullas of 16 healthy goats.

In the present study two groups of sheep have been examined, one group consisting of ten animals in advanced stages of clinical natural scrapie and the other group being composed of ten healthy animals of ages comparable to those of the scrapie animals. The method of killing the animals, fixation of brains and blocking of three levels from the medulla was exactly the same as described by Zlotnik and Rennie[2]. Eighteen serial sections from each level have been subjected to microscopical scrutiny, making a total of fifty-four sections from each medulla.

The results of this study are summarized in Tables 1 and 2, and it can be seen beyond any doubt that in animals suffering from advanced natural scrapie vacuolation of neurones in the medulla is severe, whereas in healthy animals the numbers of vacuoles are negligible when compared with those of affected

Table 1. VACUOLATION OF NEURONES IN SCRAPIE SHEEP

animals. One point, however, must be borne in mind: the finding of even seven vacuoles in a single section of the medulla alone cannot be accepted as significant, and for the diagnosis of scrapie one of the features must be the consistent presence of vacuoles in increased numbers in serial sections throughout the medulla.

I wish to thank Dr. J. T. Stamp, director of the Moredun Institute, for the interest he has taken in this work.

Improved Persistence of Dieldrin Deposits on Sorptive Mud Surface

LABORATORY experiments carried out by Hadaway and Barlow[1,2] and by Downs, Bordas and Navarro[3] have shown that solid particles of DDT may disappear from the surface of various types of soils such as are frequently used for the construction of huts in the tropics. It seemed that this disappearance was due to a process of absorption, and the different types of soils vary in their sorptive properties[4].

There is no doubt that this process of sorption into mud surfaces, which seems to occur with all commonly used residual insecticides[5], results also in loss of residual effectiveness under field conditions[6], although the effect may not be as serious as that observed under laboratory conditions where dried mud alone is used as the test surface[6].

So far, pre-spraying the mud surface with a surface-sealing material would appear to be the only practical answer, but attempts in this direction have not yielded satisfactory results[4].

The work reported here deals with experiments on a new type of wettable powder formulation consisting of ground solidified melts of dieldrin and a resinous material. The experiments were based on the assumption that the adjuvant may act as a physical barrier between at least an appreciable part of the toxicant and the sorptive surface, so that sorption might be greatly reduced, and the residual effect accordingly prolonged.

A wettable powder was prepared by mixing equal amounts of powdered dieldrin and powdered coumarone resin, which were then melted together until a homogeneous mixture was obtained. This was cooled and the brittle product finely ground, 'Teepol' being added as wetting agent. The majority of the particles were found to be within the range 10–50μ. The powder thus obtained was sprayed at a dosage of 12·5 mgm. dieldrin/sq. ft. on to laboratory-made panels constructed of dried Tanganyika (Babati) mud, having highly sorptive properties.

Enough panels were sprayed to allow for a series of tests at successive time intervals, using new panels each time. A standard 50 per cent dieldrin wettable powder, applied at twice the dosage of dieldrin, was included for comparison.

The test technique was based on a 30-sec. exposure of house-flies to the insecticidal residues. The exposure method was a 'no-choice' method. Knockdown readings were taken at hourly intervals up to 6 hr. after exposure, and the total number of dead and moribund was recorded after 24 hr. The results are shown in Table 1.

Table 1. IMPROVED PERSISTENCE OF DIELDRIN/COUMARONE RESIN SOLIDIFIED MELTS ON SORPTIVE MUD PANELS

Percentage knockdown and 24-hr. mortality

Product	Age of residue	No. of hours after exposure						
		1½	2	3	4	5	6	24
Standard dieldrin wettable powder (25 mgm. dieldrin/sq.ft.)	2 hours	91	100					100
	1 day	0	3	39	48	52	55	100
	2 days			0	9	17	37	71
	3 days		0	4	4	15	22	56
	1 week					0	2	27
	2 weeks						0	8
Dieldrin/coumarone resin melt (12·5 mgm. dieldrin/sq.ft.)	2 hours	49	85	95	100			100
	1 week	0	12	59	94	100		100
	2 weeks	17	72	97	100			100
	4 weeks	14	45	89	100			100
	10 weeks	11	22	44	78	87	98	100*
	4 months	4	27	67	87	—	100	100*
	7 months	0	2	—	52	57	82	100*
	10 months		0	13	28	44	56	100*

* Panels used for exposure more than once.

Table 1 gives a clear picture of the greatly improved persistence obtained under the test conditions. The standard dieldrin wettable powder gave a 100 per cent kill for a period of one day only on the type of mud used; then mortality figures rapidly fell with time, and the residual effect was completely lost after two weeks. On the other hand, the ground dieldrin/coumarone resin melt showed a high rate of knockdown and 100 per cent mortality throughout the experimental period of 10 months.

The favourable results obtained were shown to be, at least to a certain extent, independent of the ratio in which the two components were melted together. No appreciable differences in persistency over a period of three months were observed in tests with residues from wettable powders based on dieldrin/coumarone resin solidified melts in the ratios 90 : 10, 70 : 30 and 30 : 70.

Preliminary experiments with other insecticides (DDT, γ-BHC and aldrin) showed a similar improvement in persistence of the ground insecticide/resin melt as compared with a wettable powder without coumarone resin, but the results were less satisfactory than with dieldrin at the same dosage-level.

Improvement of the persistence of dieldrin deposits on sorptive mud is not a specific property of coumarone resin only. Similar results can be obtained by using other materials. The adjuvant should preferably be of such a nature that it can be conveniently melted with dieldrin; that the melt forms a brittle solid after cooling, so that it can easily be ground; and that the adjuvant itself is not sorbed into the mud. Synthetic and natural resins, asphaltic bitumens, petroleum and coal-tar pitches, the naturally occurring asphaltites such as gilsonite and sulphur were all tested in the same way. Chlorinated polyphenyl ('Aroclor 5460', obtained from Monsanto Chemicals, Ltd., London), colophony, gilsonite and sulphur were particularly satisfactory. With residues of 25 mgm. dieldrin + 25 mgm. adjuvant/sq. ft., a high rate of knockdown and a 100 per cent 24-hr. mortality was obtained throughout the testing period of three months, whereas the standard dieldrin wettable powder at the same dosage gave a similar performance to that mentioned in Table 1.

Although the nature of this phenomenon is not yet fully understood, there are clear indications that sorption is appreciably reduced and a sufficient amount of insecticide remains effective on the surface for prolonged periods. The work is still continuing, and will be reported in full elsewhere. I should like to thank my colleagues in this Laboratory for their help and criticism and also the management of "Shell" Research, Ltd., for permission to publish this work.

Sensitivity of Light-inhibited Seeds to Certain Spectral Regions

IN recent years important progress has been made in our knowledge of the light-dependent processes in plant development. Detailed studies of the action spectrum for the photoperiodic control of flowering and for the germination of certain light-requiring seeds, carried out by Borthwick and his co-workers[1], have shown that in both these developmental processes red light is most effective and that under certain conditions infra-red radiation reverses the effect of red illumination. The connexion between photoperiodism and seed germination was further demonstrated by the discovery by Isikawa[2] and by Black and Wareing[3] of the direct photoperiodic control of germination in seeds of a number of species.

As a corollary to our investigations of photoperiodism in the light-requiring seed of *Betula pubescens*[3], a study has been made of the effect of the photoperiodic régime on germination of *Nemophila insignis*, a light-inhibited seed. It has been found that at 21–22° C. these seeds exhibit photoperiodic behaviour with respect to germination, long days inhibiting, and short days permitting, germination. These effects are profoundly modified by temperature. Further details of this work will be published elsewhere.

During this investigation, an examination has been made of the effects of different regions of the spectrum on germination of *Nemophila*. Facilities for a detailed study of the action spectrum were not available and only white, red, blue and infra-red radiation were used. As a source of white light, 'daylight' fluorescent tubes were used. Red light, within the band 5,800–7,000 A., was obtained from red fluorescent tubes in conjunction with red 'Perspex' (*R*.400) as a filter. To obtain blue light, blue fluorescent tubes were used in conjunction with blue 'Perspex' (*B*.705) and copper chloride filters, transmitting the wave-lengths 4,000–5,200 A. Light from a 150-watt tungsten filament lamp passing through the Ilford infra-red filter 207 and a 9·5-cm. thick water screen gave infra-red radiation of the wave-lengths 7,300–10,000 A.

White fluorescent light at an intensity of 1,200 ergs/cm.^{2}/sec. (lower intensities have not been tested) was found to inhibit seed germination at 21–22° C. Seeds were exposed to red and blue light over a range of intensities at this temperature. The germination percentages obtained under each treatment are shown in Table 1. These results demonstrate that both blue and red light inhibit germination, and that at the lower intensities blue light is more effective.

Table 1. THE INHIBITORY EFFECT OF BLUE AND RED LIGHT ON THE GERMINATION OF *Nemophila* SEED. TEMPERATURE 21–22° C.

Intensity (ergs/cm.^{2}/sec.)	Percentage germination Red	Blue
3,000	27·5 (89·4)	25·6 (91·6)
2,300	32·4 (87·3)	29·5 (94·2)
1,900	33·3 (88·2)	27·0 (92·3)
1,300	34·5 (91·0)	25·4 (93·7)
1,000	60·0 (96·9)	22·7 (95·0)
800	59·0 (94·4)	19·3 (93·0)
500	55·3 (90·0)	40·5 (92·6)

The figures in parentheses indicate the percentage germination of the dark controls.

On the other hand, it has been found in a number of experiments that germination of *Nemophila* seed is not inhibited by infra-red radiation at an intensity of 4,000 ergs/cm.^{2}/sec. From a knowledge of the spectral emission data for 'daylight' fluorescent tubes[4] it can be calculated that in white fluorescent light, at an intensity of 1,200 ergs/cm.^{2}/sec., the infra-red component is approximately 15·6 ergs/cm.^{2}/sec. Thus, it appears unlikely that the inhibitory effect of white light is due to its infra-red content.

These results are not in agreement with the suggestion put forward by Meischke[5], that the germination of seeds of certain species is inhibited by light from a tungsten filament source because the inhibitory effect of the infra-red content overcomes the effect of promotive wave-lengths. The results also contrast with the findings of Baxter-Jones and Bailey[6] for *Lamium amplexicaule*, which tend to support Meischke's hypothesis. Furthermore, it appears that in *Nemophila* seed we have an example of an action spectrum for germination which, because of the greater effectiveness of blue light, is not in accordance with the typical action spectrum elucidated by Borthwick and his co-workers[1], but which is similar to the findings of several Dutch workers[4,7] for the dependence on wave-length for flowering in *Hyoscyamus* and other plants.

In the present investigation it is unlikely that the inhibitory effect of blue light is due to its infra-red component since the light from the fluorescent tubes was filtered through a solution of copper chloride. The infra-red content must therefore have been very low.

It is hoped that in future work a detailed investigation of the inter-relationships between blue, red and infra-red radiation will be carried out.

FORTHCOMING EVENT

Thursday, August 29—Thursday, September 12

ENGINEERING, MARINE AND NUCLEAR ENERGY EXHIBITION (at Olympia, London).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

SENIOR RESEARCH STUDENT IN EITHER ENGINEERING OR CHEMICAL ENGINEERING OR METALLURGY—The Registrar, University College, Singleton Park, Swansea (August 28).

DEPARTMENTAL ASSISTANT (with an honours degree in botany) IN THE DEPARTMENT OF BOTANY—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (August 30).

PROFESSOR OF MECHANICAL ENGINEERING at Santa Maria Technical College, Valparaiso, Chile—The Director, Personnel Department, British Council, 65 Davies Street, London, W.1, quoting N.2 (57) (August 30).

ASSISTANT, Grade B, IN PHYSICS; and an ASSISTANT, Grade B, IN CHEMISTRY—The Principal, Nottingham and District Technical College, Shakespeare Street, Nottingham (August 31).

ELECTRON MICROSCOPIST (with a degree in science or equivalent qualification, previous experience in electron microscopy, a good knowledge of electronics, and ability to service the microscope) IN THE VIRUS RESEARCH UNIT, Agricultural Research Council, Cambridge, for work on viruses—The Secretary, Agricultural Research Council, 15 Regent Street, London, S.W.1 (August 31).

PROFESSOR AND HEAD (with academic qualifications and research or development experience appropriate to a postgraduate department studying gas turbines, jet propulsion engines and rockets, with an increasing emphasis on high-temperature problems and nuclear power) OF THE DEPARTMENT OF AIRCRAFT PROPULSION—The Principal, The College of Aeronautics, Cranfield, Bletchley, Bucks (August 31).

ASSISTANT EXPERIMENTAL OFFICERS (2) (preferably with a degree in a biological subject; or at least G.C.E. in five subjects with advanced level in botany, zoology and chemistry) with the Ministry of Agriculture, Fisheries and Food, stationed at Hull and Nottingham, for research on insect control—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting G 262/7A (September 7).

ASSISTANT LECTURER, Grade A (male), TO TEACH APPLIED MATHEMATICS AND PHYSICS to the standard of General Certificate of Education Ordinary level, at the Dockyard Technical College, Malta—The Director (Y), Education Department, Admiralty, London, S.W.1 (September 9).

DEMONSTRATOR IN BOTANY—The Registrar, The University, Leeds (September 9).

HEAD (with a degree of a British University and appropriate research and administrative experience) OF THE DEPARTMENT OF SCIENCE, Royal Technical College of East Africa, Nairobi—Council for Overseas Colleges of Arts, Science and Technology, 1 Woburn Square, London, W.C.1 (September 10).

SENIOR LECTURER and LECTURER (with previous experience in an institution of higher education, and preferably a member of a main professional Institution) IN ENGINEERING at Fourah Bay College, Sierra Leone (University of Durham)—The Secretary, Council for Overseas Colleges, 1 Woburn Square, London, W.C.1 (September 12).

ASSISTANT IN BOTANY—The Secretary of University Court, The University, Glasgow (September 13).

LECTURER IN NATURAL PHILOSOPHY (ELECTRONICS)—The Secretary, The University, Aberdeen (September 15).

LECTURER IN CHEMISTRY (INORGANIC) at Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, September 20).

LECTURER IN THE DEPARTMENT OF GEOLOGY, Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, September 20).

MAY AND BAKER RESEARCH FELLOW (graduate in science who has specialized in biochemistry), to undertake research work on plant growth regulating substances—The Registrar, Wye College, near Ashford, Kent (September 21).

LECTURER IN MATHEMATICS at Canberra University College, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 28).

LECTURER IN MATHEMATICS; and a LECTURER IN MATHEMATICAL STATISTICS at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, September 30).

LECTURER IN THE DEPARTMENT OF GEOLOGY, Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, September 30).

LECTURERS or ASSISTANT LECTURERS IN MATHEMATICS—The Registrar, The Manchester College of Science and Technology, Manchester 1 (September 30).

REGIUS PROFESSOR OF PHYSIOLOGY in the University of Aberdeen—The Private Secretary, St. Andrews House, Edinburgh 1 (September 30).

PROFESSOR OF HORTICULTURE—The Registrar (Room 9, O.R.B.), The University, Reading (October 15).

CHEMIST/ASSAYER (with a first- or upper division second-class honours degree in chemistry, and preferably two years postgraduate research or experience as a chemist) IN THE DEPARTMENT OF GEOLOGICAL SURVEY, Government of Northern Rhodesia, to carry out assays of ores, analysis of minerals and rocks and other determinations in the Geological Survey Laboratories—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.105/3/03.

FISON RESEARCH FELLOW (suitably qualified graduate) IN THE DEPARTMENT OF BIOLOGICAL SCIENCES, for work in connexion with nutritional studies in relation to plant virus diseases—The Registrar, Wye College, near Ashford, Kent.

GEOLOGIST (with a first- or second-class (upper division) honours geology degree) with the Government of Sarawak, for duties mainly concerned with field mapping—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.105/127/01.

JUNIOR TECHNICIAN/TECHNICIAN (preferably with an interest in biochemistry) IN THE CHEMICAL PATHOLOGICAL LABORATORY—The Secretary, The National Hospitals for Nervous Diseases, Queen Square, London, W.C.1.

LABORATORY TECHNICIAN (ZOOLOGY) (preferably with experience of biological techniques)—The Registrar (ZT), Queen Mary College (University of London), Mile End Road, London, E.1.

SPECIALIST OFFICER (HORTICULTURIST) (with a good honours degree in an appropriate branch of science followed by at least two years postgraduate training or approved experience, and normally not less than 23 or more than 30 years of age) in the Region of Northern Nigeria, to develop the cultivation of fruit trees and tree crops (citrus, coffee, cocoa, oil palm, etc.); test local and imported material; develop techniques of propagation cultivation and management; and ascertain most suitable root crops in various areas—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/408/033.

ZOOLOGIST (male, preferably with a first- or good second-class honours degree), for work on the maintenance and infection of bilharzia snail vectors and other problems of bilharzia disease—The Director, Medical Research Council, Bilharzia Research Group, Winches Farm, Hatfield Road, St. Albans, Herts.

When, for security or other reasons, illustrated reports must be produced on the premises, 'Kodalith' Autoscreen Ortho Film will enable you to print them yourself on a small offset machine.

'Autoscreen' film, which has the half-tone dots incorporated in the emulsion, makes it possible to reproduce photographs, line drawings and typed or printed matter at the same time. The negative can be made with an ordinary sheet-film camera.

'Kodalith'

AUTOSCREEN ORTHO FILM

made by **Kodak**

Please write for details.

Kodak Limited, Industrial Sales Division
Kodak House, Kingsway, London, W.C.2

'Kodalith' and 'Autoscreen' are trade-marks

AUTOMATIC TITRATIONS

ARE easily carried out by the E.I.L. Automatic Titrimeter, Model 24. This instrument is fully automatic, switching itself off on reaching the pre-set end point.

Either the volumetric or the coulometric method may be used, and separate titration units for each type are available. Duplicated connections are provided on the Control unit.

The endpoint setting dial is calibrated in pH and in millivolts, and the equipment can be used for any type of chemical reaction producing a determinate change of e.m.f. The accuracy of titration is 0.05 c.c. in 50 c.c.

RESEARCH AND DEVELOPMENT IN NUCLEAR ENERGY

THE third annual report of the United Kingdom Atomic Energy Authority* provides an impressive picture of the many-sided contribution which the work of the Authority is making to Britain's economic development. It does not, however, make possible an assessment of the magnitude of the Authority's demand upon the resources of the country in either man-power or materials. Much of the material in this report will be already familiar to readers of *Nature* from the re-consideration of the nuclear power programme and capital investment in the fuel and power industries which has followed on the success of the Calder Hall station, so that recapitulation seems unnecessary. It should suffice to note that the report provides a convenient and authoritative means of following the progress of events, and to pass on to other matters of scientific and technical interest. The operating account continues to be withheld from publication in the interest of national security, and the balance sheet merely shows an item of £2,691,341 for research and development expenditure in aid of design. It may also be noted that the whole of the cost of operation of the Research Group, less the proceeds of sales of radioactive substances, electronic equipment and other income, is regarded as fundamental research in the nuclear energy field and as such is borne by the Exchequer. Similarly, the cost of operation of the Weapons Group which, besides other research and development, undertakes the production of components for weapons and research work in connexion with weapons, less the amounts chargeable for such work under contract to the Ministry of Supply, is regarded as a charge to be borne by the Exchequer.

On the staff side, the expansion of the Authority continued at a high level, non-industrial staff increasing from 10,795 to 12,630 at March 31, 1957, and industrial staff from 13,178 to 14,660, the greatest difficulties in recruitment being in the more senior posts, especially in engineering. These figures do not, of course, give any accurate indication of the demand on the nation's scientific and technical man-power; but the Authority is making a positive contribution in this field. As a result of a review of its own training facilities in the light of the White Paper on Technical Education, a revised scheme of awards has been introduced to enable selected members of the staff to attend university and 'sandwich' courses. The first bursaries for full-time university courses were awarded in May 1956, and systematic selection of candidates for 'sandwich' courses in technical colleges started in time for the January 1957 term. Besides this, 471 students have already passed through the Reactor School at Harwell, more than 900 students through the Isotope School, and the first course in the school at Calder Hall for training reactor operators for power stations was attended by eight students. Students for these courses, which in future will last six weeks, will be expected to have attended the Reactor School at Harwell or to have reached a comparable standard of knowledge. In addition to the three-and-a-half month full courses at the Reactor School, two short courses, the first of several new courses made possible by the expansion in capacity of the School, have been given to industrial executives with the view of giving senior industrialists a general appreciation of the problems and possibilities of nuclear power. Moreover, to keep industry broadly informed of work in progress which might eventually lead to industrial application, the Authority arranged some ten conferences during the year to which representatives of industry were invited, with the view of acquainting industry with the possibilities that are being examined so that firms may think about applications in their own fields and provide for discussion of the lines of development being followed.

In spite of the steady flow of inquiries from industry, mostly from firms which were unaware of the large amount of published information available, few 'access agreements' have as yet been negotiated. The Authority has also directed the attention of individual firms to inventions of interest in their own particular fields. Apart from inventions of major importance to the nuclear power programme, the Authority now has some 230 inventions protected by patents and patent applications, covering a wide range in the chemical, metallurgical, electronic and instrument fields, and up to the present, thirty-nine patent licences have been granted to British firms and six to firms in other countries. Besides this, as a result of the eighth Tripartite Declassification Conference between the United Kingdom, the United States and Canada, held in the United States early in the year, and ratification of its recommendations, virtually all technological information needed to develop a civilian nuclear power industry, including a very wide range of information on the design, construction and operation of power reactors, together with details of the metallurgy of fuel materials, the fabrication of fuel elements and the effect upon them of radiation, has been freed from security restrictions on publication.

These changes will permit the greatest release of information on nuclear energy since the Conference on the Peaceful Uses of Nuclear Energy at Geneva in August 1955, and the Authority has undertaken to review all existing classified reports to see which can be made available to the public. The more useful of these will be reprinted, and periodical lists will be issued of the others; it will be possible to borrow these from the Authority's libraries. Much else is done by the Authority to disseminate information on nuclear energy both by papers by the Authority's staff in the scientific and technical press, which during the year numbered 450, and by the issue of lists of new publications acquired by the Authority's libraries, information bulletins and bibliographies on selected subjects. Indeed, it would appear that, within the limits set by official policy, the Authority is already doing all that can reasonably be expected to facilitate the dissemination of technical information in this field, as well as to promote the necessary training of scientists and engineers drawn from British industry and from overseas.

---

* United Kingdom Atomic Energy Authority. Third Annual Report for the period 1st April 1956–31st March 1957. Pp. vi+56. (London: H.M. Stationery Office, 1957.) 3s. net.

It is, of course, essential that a proper balance should be achieved between national security on one hand and the rapid advance in the peaceful applications of nuclear energy on the other; accordingly it is important that scientists in general should take every opportunity to ensure that the dangers of excessive secrecy are clearly understood, and also the dependence of national security on the positive achievements of technology rather than on any negative measures. This applies to staff no less than to information. The more interlocked with industry the Authority's part in the application of nuclear energy becomes the more essential it is that there should be free movement of staff and of information, and that such movement and interchange should not be hindered by restrictions that cannot be clearly shown on continuous scrutiny to be essential for national security.

This is sufficiently illustrated by the Authority's clear concern with the export of reactors, to which the report refers. Although this is the responsibility of industry, the Calder Hall type of reactor is the only type of power reactor of British design at present available for export from the United Kingdom; and, as its designers and operators, the Authority is well qualified to describe its features and advantages to potential customers. The Authority is also responsible for supplying the fuel elements for reactors of British origin exported by industry, and it has a part to play in the inter-government negotiations required in such transactions.

No overseas orders for British power reactors of British design had been received from overseas up to the end of the year under review, although the A.E.I.–John Thompson Co. had received an order for a Merlin research reactor from the German Land Government of North Rhine–Westphalia, which had also authorized the purchase of a DIDO-type of high-flux research reactor. This development aspect may possibly repay a little further attention, and clearly the more contacts between the Authority and industry are facilitated the more effectively industry will be able to make its full and natural contribution to development, as well as to the reactor research programme and to research and development in general. As regards the reactor research programme, the concept of three successive stages has now been abandoned in favour of a more flexible pattern of development, and while the gas-cooled, graphite-moderated system continues to show even greater potentialities than at first thought, work on the sodium-graphite system continues, a high-temperature zero-energy critical assembly is to be built and good progress is being made with the experimental fast reactor at Dounreay. The technological problems involved in the homogeneous aqueous and liquid-metal-fuelled systems are also being examined, as well as possible systems for surface ship propulsion, in addition to work on the development of the pressurized water reactor for submarine propulsion.

The references in the report to these technological investigations give some idea of the far-reaching influence of the Atomic Energy Authority's work on industrial development. For example, in collaboration with industry, the Research and Development Branch of the Industrial Group is investigating the development of steels for pressure vessels which will operate at higher temperatures and pressures. In work on fast reactor systems, conditions have been established for alloying uranium with chromium which improve the creep strength and minimize swelling on thermal cycling, and for casting the alloy into tubes within close dimensional tolerances. Chemical work on homogeneous aqueous reactor systems has included investigations into the stability of uranium and plutonium solutions at high temperatures and pressures and under high radiation flux, and into the behaviour of thorium oxide slurries, while the trend in development of fuel elements for advanced reactors has been towards ceramic, rather than metallic, elements, because the evidence now available indicates that ceramics may be more suitable for high-temperature operation. Techniques are being developed for fabricating and welding zirconium alloys which possess higher creep-resistance than zirconium itself.

About a fifth of the work at Harwell is devoted to fundamental research, and this work, in particular the study of the physics of solids, has yielded results of wide utility. For example, the behaviour of graphite under neutron irradiation can now be deduced from a knowledge of its crystal structure; this has permitted a correlation between neutron-induced damage and changes in the electrical properties of the graphite. Reactors have made possible the new technique for solid-state studies known as neutron diffraction, in which beams of neutrons are used for exploring the atomic architecture of solids, while a group working on cosmic rays is studying the variation with time in the occurrence of big showers of cosmic-ray particles. Fundamental research in chemistry has included studies of practically all the radioactive heavy elements, while developments in the technique of chemical analysis by neutron activation have led to interesting results in pure as well as in applied chemistry, including a technique used, in the manufacture of transistors, to determine as little as one part of copper in ten thousand million of silicon and also the minute traces of gold in sea-water with an accuracy which has confirmed Haber's conclusion that most of the gold is associated with particulate matter. The Authority is also providing to the Colonial Geological Surveys an improved form of ratemeter, produced by manufacturers of electronic equipment and conforming to a specification laid down by the Electronics Division at Harwell, working on torch batteries and which has a long life in the field.

If, therefore, it is difficult, on the information available, to assess how far the expenditure on the Atomic Energy Authority is in balance with the *national* expenditure on research and development as a whole, there can be no question as to the value of the return received from that expenditure. When such an assessment cannot well be made from published information, it is all the more important that the general arrangements should inspire confidence that the assessment is being made within the organization itself and used for guiding policy. For that reason alone it is unfortunate that there is no indication of any intention either to strengthen the staff of the Lord President's office, to provide him at the least with a direct spokesman in the House of Commons, or to fill the office with a Minister whose sole responsibility is to discharge those onerous duties.

There are two further reasons for concern at this delay to deal adequately with the question of the Lord President's responsibilities and with the resources of his office. It is not simply a question of seeing that Britain's research and development effort is in proportion, but also of the division of ministerial responsibilities. The development of an export trade in reactors, which, it is confidently anticipated, might reach the scale of £50 million a year within a decade, involves questions of international trade and relations, and in particular of Britain's position with regard to Euratom and the International Atomic Energy Agency; just as the nuclear power programme is essentially the responsibility of the Minister of Power, but equally is determined by decisions as to the extent of our capital investment made by the Chancellor of the Exchequer. This programme also impinges on that of the use of land generally and, while the desirability of accelerating the execution of the programme cannot be denied, there is reason in the argument of the Council for the Preservation of Rural England that the preparation of a master plan by the Minister of Housing and Local Government is a matter of extreme urgency to prevent the haphazard piecemeal selection of sites.

This third report of the Atomic Energy Authority just touches on two instances which well illustrate this need. The Secretary of State for Scotland has now given his consent to the construction of a 300–320 MW. nuclear power station at Hunterston in Ayrshire; but the delay of nine months between the letting of the contract and the starting of building work means not only a serious interruption of the orderly development of the nuclear power programme, but also that a smaller power station will be built for the same cost than if the Electricity Board had been able to wait until now before settling the details of the contract. It is to the public interest that such delays should be kept to a minimum, just as it is that there should be no over-riding of other interests.

This delay might well be minimized if consent were sought, under such a master plan, at the earliest possible stage. Not only would justice be manifestly seen to be done, but also under a master plan much opposition and obstruction would disappear. It is the piecemeal approach and the fear that the Authority or Ministry is being allowed to judge its own cause that gives rise to legitimate anxiety and opposition. This is equally illustrated by the difficulties that have arisen over the selection of a site for another major research establishment and which led to the introduction of the Winfrith Heath Bill in the House of Commons on May 21, 1957. Despite the care taken by the Authority in the examination of possible sites, the debates in Parliament testify to the weakness in the present procedure and the unnecessary fears that can be aroused; and it is to be hoped that the suggestion thrown out by the Council for the Preservation of Rural England will receive the careful examination it merits.

The chapter on international relations in the present report could not be expected to provide critical comment on the international situation to-day, though it does illustrate its complexity. What is required is that the Government should decide on its policy towards the Organization for European Economic Co-operation in this field, and towards the Euratom countries. It is of the utmost importance that the opportunities opening before Britain in that field, as well as under the Baghdad Pact, are not missed through failure to co-ordinate policy or to place adequate resources at the disposal of those responsible for its execution. Above all is the need for a wide outlook and imaginative approach in place of the piecemeal and haphazard dealing that has caused frustration and waste in the past.

WITTGENSTEIN'S ACCOMPLISHMENT

Philosophical Investigations
By Ludwig Wittgenstein. Translated by G. E. M. Anscombe. (Text in German and English.) Pp. x + 232. (1953.) 37*s.* 6*d.* net.

Remarks on the Foundations of Mathematics
By Ludwig Wittgenstein. Edited by G. H. von Wright, R. Rhees and G. E. M. Anscombe. Translated by G. E. M. Anscombe. (Text in German and English.) Pp. xx + 204. (1956.) 37*s.* 6*d.* net.
(Basil Blackwell, Oxford.)

THESE two stately volumes (briefly, "Investigations" and "Foundations") are the work of a thinker who is likely as the years go on to stand out more and more distinctly as the possessor of a mind almost without parallel in the long and complex history of philosophical research. At the same time, they manifest the courage and foresight of the publishers in undertaking (whatever the financial arrangements may have been) a task unlikely to appeal to more than a very limited number of readers. Like the "Tractatus" of 1922, the English and German versions are printed on opposite pages, which enables the reader to do two things. These are, first, to get as deeply as possible into the author's mind via his native tongue, and secondly to realize how difficult it is to render into another language ratiocination at this sustained level of spontaneity.

Even so, there are a few instances in which a happier English word could have been chosen without doing any violence to the original, and might, indeed, have added a little to its dignity. But one is grateful all the same for a faithful translation, acceptable in all essentials. As for the editors, they have discharged a most delicate duty with judgment, for the assembling of manuscripts like these, including some and rejecting others, must always be to invite criticism of one kind or another.

The plan of "Foundations" is to present the master's thoughts in five parts, of which Part 1 is largely correlative with portions from the "Investigations". Part 2 deals with the derivability of arithmetic from the calculus of logic. Part 3 contains the necessary preliminary matter for the understanding of the relation between mathematical and empirical propositions, referred to at length in Part 5. In Part 4 come Wittgenstein's speculations on intuitional mathematics, and the law of the excluded middle, while Part 5 includes, among other topics, a somewhat peripheral approach to Godel's theorem.

Broadly, Wittgenstein is struggling manfully with a problem well-nigh insoluble, namely, the nature of language, and what that nature (if it can ever be fully revealed) permits it to do for the purpose of communication between human beings, both in everyday affairs and in the domain of scientific reasoning. Nobody would expect such an investigation to be more than a sketch within the life-time of an individual however gifted; the reader will nevertheless be fascinated by the author's intellectual humility and sense of failure. If ever two books betoken a pain in the mind, these assuredly do. This leads one to compare these pages with a supreme picture left unfinished by an artist, as if to suggest that—in part, at least—in its incompleteness resides its majesty. Michelangelo's "Entombment" is a case in point: not for a moment could this composition be envisaged as 'finished' without wrecking much of its appeal to our æsthetic sense; and so it is for these intuitive flashes from the brain of Wittgenstein. We are confronted with something akin to a mental workshop, a scene scarcely beautiful at first sight, but capable of almost infinite refinement as its power is recognized. Canon Streeter, some years ago, felt in need for much the same equipment in planning his work on "Reality"; somewhere wherein thoughts could, so to say, be left lying about, in sure trust that they were secure against being tidied away overnight. But this is perhaps a privilege to be claimed in its entirety by genius, and by genius alone.

Wittgenstein's methodology, for example, shows this formative character in its tentative approach. He asks what difference there is between cause and motive, and how these may be discovered. We make no progress by being told what 'motive' is, and what 'judging' is. In other words, attaching a definitive label to the entities under consideration gets us nowhere. More physically, if it is desired to measure a length, the meaning of the word is learnt by learning what the process of measurement involves. Thus, there is both a physical and conceptional connotation attaching to the word 'methodology'. In such a context, it has always seemed to me that the Michelson–Morley experiment stands not only at the apex of ether physics, but that it was also the summit of speculative thought at that particular period. Here, from the point of view of pure epistemology, comes a throw-back, as it were, to that phase of natural philosophy which is not in the least belittled by a negative result. The methodology of physics (like its metaphysics sometimes) is inclined to be a little amateurish: Wittgenstein's broadening of the theory of knowledge in this way should be an additional source of strength as techniques develop.

In the event, mathematicians are considered more as inventors than as discoverers. Queer as this may seem at first sight, it is just this inventive quality which has enabled ratiocination to break through to concepts on the very limits of human endeavour. It has also provided much of the power for the advance in theoretical physics during, say, the past century and a half, if we include the fundamental place occupied by non-Euclidean geometries in cosmology.

With the death of Ludwig Wittgenstein in 1951 ended a career in many respects tempestuous, but full of promise, and (though he would have denied it hotly) of achievement. He has left so much behind for the benefit of mankind. Without qualification, it may be said of him that in thus labouring he entered into his rest. F. I. G. RAWLINS

WEBER PARABOLIC CYLINDER FUNCTIONS

Tables of Weber Parabolic Cylinder Functions

Edited by Dr. J. C. P. Miller. Pp. 233. (London: H.M. Stationery Office, 1955. Published for the Department of Scientific and Industrial Research.) 63s.

THIS is an admirable example of a scheme which Dr. Miller is well known to favour—a unified analytical and numerical treatment of a particular mathematical function. Systematic study of special functions is now the province of those who make fundamental numerical tables, and this volume, although published separately, is an offshoot of the general activity represented by the British Association and Royal Society Tables Committees.

Weber's equation $y'' + (A - Bx^2)y = 0$ is physically significant in several ways; for example, when parabolic-cylinder co-ordinates are applied to the equation of harmonic waves. With $B > 0$ it can be the Schrodinger equation of a harmonic oscillator. It can occur in approximations to partial differential equations of parabolic type, for example, in boundary-layer theory. Alternatively, it is a third approximation to the general linear equation in its 'normal form' $y'' + I(x)y = 0$, and Section 2 of Miller's introduction examines this aspect. The case where $I(x)$ is linear leads to Airy's equation; the present volume is really a successor to Miller's "Airy Integral" (British Association Tables, Part-volume B, 1946).

The standard forms discussed are (1) $y'' - (\frac{1}{4}x^2 + a)y = 0$, and (2) $y'' + (\frac{1}{4}x^2 - a)y = 0$, where the real constant a may be positive or negative. Eighty pages are devoted to the theory of (1) and (2), including (pp. 61–89) an invaluable list of "Functions and Formulæ". The tables (140 pages) unfortunately deal only with (2). An important feature is the correct choice of a standard pair of solutions, which should be 'numerically independent' over a wide range, taking into account that (1) and (2) may exhibit both exponential and oscillatory regions. The tabulated solutions of (2), $W(a,x)$ and $W(a,-x)$, are such that they differ in phase by $\pi/2$ in oscillatory regions and change in magnitude across exponential regions by the greatest possible amount. Table 1 (84 pages) gives $W(a,x)$ and $W(a,-x)$ on facing pages for $a = -10(1)10$, $x = 0(0\cdot1)10$, to about 8 figures. Reduced derivatives for x-wise interpolation by Taylor series are fully tabulated. Various auxiliary functions occupy Tables 2–6 (56 pages), including ln $W(a, \pm x)$ in exponential regions, and the modulus and phase of $W(a, \pm x)$ in oscillatory regions.

This review is slightly improper, in that I was intimately concerned with some of the basic calculations; but (such is the gestation period of a volume of good mathematical tables) eleven years have passed without my having further contact with the work. I therefore feel impartial in welcoming this production of Scientific Computing Service, Ltd., sponsored by the National Physical Laboratory through its Mathematics Division, the constructive influence of which on this and other table-making projects has been considerable. The volume has been very well printed by H.M. Stationery Office.

C. W. JONES

FOSSIL BRACHIOPODS

Chazyan and Related Brachiopods

By G. A. Cooper. Part 1, Text: Pp. xvi+1–1024. Part 2, Plates: Pp. 1025–1245+269 plates. (Washington, D.C.: Smithsonian Institution, 1956.)

THE publication of a monograph describing a supposedly well-known brachiopod fossil fauna in which sixty-nine new genera and more than six hundred new species are proposed is an occasion for some reflexion on the function of the systematist in the realm of palæontology and the wider world of geology. Theoretically, of course, a palæontologist, like his counterpart in the biological sciences, may indulge in identification and classification without further motive. But in practice he is usually fully aware of the possible consequences of his activities, for it is inevitable that they will, sooner or later, influence decisions on stratigraphical correlation on one hand and inquiries into the processes of evolution on the other. These are purposes which demand the exercise of somewhat different methods in faunal investigations so that only rarely is an attempt deliberately made to provide detailed and pertinent information for both fields of knowledge, and, in his study of "Chazyan and Related Brachiopods", Dr. Cooper is no exception, for he has written what is primarily a stratigraphical guide to the Lower and Middle Ordovician rocks of North America based on comparisons of brachiopod faunas.

In this context, Dr. Cooper has succeeded to such a degree that his study is one of the ablest stratigraphical syntheses deriving from the taxonomic analysis of fossil assemblages yet conceived, a truly remarkable demonstration of the advantages as well as the limitations of correlation by faunal association. Doubtless many stratigraphers will feel alarmed at the prospect of so many new names flooding into Ordovician literature but, relative to the scope of this work, the size of collections and the spectacular success of a sustained etching programme for the recovery of chitinous and silicified shells, his new genera and species are not unreasonably prolific. It is true that exception will certainly be taken by other students of the phylum to some aspects of systematic procedure adopted by him. A few of the genera like *Chaulistomella*, *Apatomorpha* and *Glyptambonites* are, in my opinion, too finely drawn, as are some of the new species, especially those founded on size differences, for no attempt has been made to analyse the supposed differences quantitatively. Nevertheless, these discrepancies are really minor, for the majority of his taxonomic units are surely destined to withstand the test of time, and reference to them is facilitated by well-organized systematic descriptions supplemented by brilliantly executed illustrations.

The most inadequate section is undoubtedly that on evolution. Admittedly, the author had no intention of giving more than a few brief interpretative notes on the morphological development and change exhibited by the faunas he has described, and what comments there are are very instructive. Yet it is not unreasonable to judge them insufficient in view of the abundance and magnificence of material so patiently collected and prepared by the author. Surely the discovery of so many bizarre forms and the possession of what must be reasonably complete samples throughout the ranges of a number of related stocks deserves a more detailed appraisal of evolutionary changes affecting the phylum during those times. It is hoped that some such study is forthcoming; in the meantime, Dr. Cooper is to be congratulated on the completion of the most significant contribution to Appalachian geology since 1859.

ALWYN WILLIAMS

PULSE CIRCUITS AND MULTIVIBRATORS

Elements of Pulse Circuits

By Dr. F. J. M. Farley. (Methuen's Monographs on Physical Subjects.) Pp. viii+143. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1956.) 8*s*. 6*d*. net.

Analysis of Bistable Multivibrator Operation

The Eccles-Jordan Flip-Flop Circuit. By P. A. Neeteson. (Series on Electronic Valves, Vol. 10.) Pp. vi+82. (Eindhoven: N.V. Philips' Gloeilampenfabrieken; London: Cleaver-Hume Press, Ltd., 1956.) 15*s*.

THIS addition to the Methuen series of monographs on physical subjects provides a concise introduction to the principles and use of pulse techniques, and is addressed primarily to physicists and research workers. The fundamental principles of pulse wave-forms and of the use of differentiation and integration techniques are described, together with their application to various valve circuit arrangements. Chapter 3 deals with square-wave generators of the multivibrator and other types; and the next chapter illustrates the various arrangements of trigger circuits, including the classical scale-of-two circuit first described by Eccles and Jordan. Later chapters deal with time bases and pulse amplifiers, concluding with one on applications of these circuits to such fields as radar, television, counters and particle detection. Many of the circuit diagrams in the last chapter contain sufficient description of the valves and components to enable the experimenter to set up the practical arrangements as may be desired.

This handy volume is ideal as an introduction to the subject for research workers and engineers; and, while no attempt has been made to provide a complete bibliography, a short list of useful books and references is appended for readers who wish to pursue the subject in more detail.

Two pulse-operated thermionic devices were described in 1919 and must to-day be regarded as classical advances in electronics technique. Prof. W. H. Eccles and F. W. Jordan, in a paper read before the British Association, described a one-stroke relay: this was a combination of two triodes with resistance coupling which, when operated by a small electrical impulse, changed from one condition of equilibrium to a second, in which it remained until reset by the application of a pulse of the opposite sign. This device is commonly referred to as a 'flip-flop' circuit or perhaps, more elegantly, as a bi-stable multivibrator.

The term 'multivibrator' was, however, more appropriately applied to the device described in the same year by H. Abraham and E. Block. They used a somewhat similar combination of valves, but with capacity coupling, so that the flip-flop action was maintained, and the arrangement became a source of oscillations rich in harmonics, and therefore suitable for frequency measurement.

During the past decade or so, these multivibrator circuits have found wide application in the field of computer development and pulse-counting technique. In the book under notice, the author directs attention to the fact that all previous work on the design of such circuits has considered only the stability of the static condition. Prompted by a practical problem, a thorough investigation of the dynamic behaviour of the bi-stable multivibrator was undertaken and is presented in this book. Consideration is given to the overall sensitivity in relation to valve characteristics; to the triggering speed and to the fundamental principles of design. Some numerical examples have been worked out to illustrate the application of the theoretical treatment, the results of which have been used in the development of special valves for multivibrator operation. The book should be very useful to designers of electronic computers, counters and allied devices.

R. L. Smith-Rose

ATMOSPHERIC ELECTRICITY

Atmospheric Electricity

By Dr. J. Alan Chalmers. Pp. viii+327. (London and New York: Pergamon Press, 1957.) 63s. net; 10 dollars.

Atmospheric electricity, as a subject for research, is passing through a rather difficult transitional stage. No longer really viable as a separate field of study, it has yet to become integrated into meteorology in general, and cloud physics in particular, in a manner which may prove necessary to its future advancement. The electrical behaviour of the atmosphere in fine weather, to which so much effort has been devoted in the past, is now fairly well understood; although there are still interesting problems to be investigated, they are not currently in favour or fashion. Attention is now focused on the thunderstorm, for here the central problems, which are still essentially those which troubled Franklin two hundred years ago, remain unsolved. But recent researches make it increasingly clear that the origin of the electric charge in thunderstorms and the mechanism of the lightning discharge are matters closely associated in clouds with the complex physical and dynamical processes which lead to the development of precipitation, and it seems only sensible that they should be studied in this wider setting. Such an orientation is already perceptible, and one feels that the atmospheric electrician of the future may find it increasingly difficult to manage with occasional self-conscious references to convection, *Austausch* and turbulence as though they were passwords to a secret society. He must break down his resistance to meteorological indoctrination or risk finding himself insulated at infinity with no conducting path either to earth or reality.

The feeling that such a change is almost inevitable is strengthened after reading Dr. J. A. Chalmers's "Atmospheric Electricity", a revised and considerably enlarged version of his book of the same title published in 1949. Although the intervening period has been one of steady consolidation rather than of spectacular new advances, a large number of new papers has appeared, many of which describe work carried out during the Second World War. An up-to-date account of the subject is therefore to be welcomed, and little of the material published up to the end of last year has escaped Dr. Chalmers's attention.

The book opens with a short historical introduction; this is followed by a chapter of some forty pages summarizing basic principles, concepts and known facts which will prove helpful to the newcomer to the subject. Here the author introduces the MKS system of units which he uses throughout the text. The next four chapters, which describe various aspects of the fine-weather field with the proper emphasis on experimental techniques and results, are probably the best in the book. There follow three chapters dealing with point-discharge currents, precipitation currents, and the transfer of charge between the atmosphere and the Earth. Only forty-five pages are devoted to the thunderstorm, including chapters on the lightning discharge and the theories of charge generation and separation; this seems rather inadequate in view of the importance of this part of the subject.

The treatment throughout is sound and clearly written, and will be useful both as a text-book and a source of reference. But I feel that some topics might have been discussed in greater depth and in more detail. It is a pity that the author has divided the text into so many short paragraphs numbered serially throughout the book. The frequent appearance of heavy black headings, often three on a page, frequently breaks the flow in the argument, and gives the whole text the appearance of an expanded card index. There are times when Dr. Chalmers leans too far towards impartiality in mentioning every paper which bears some relation to the topic under discussion. For the benefit of his less-experienced readers one wishes he had been less modest in expressing his opinions of the work he describes so clearly. In being kind to everyone he has been less than fair to himself.

The book is well produced, has a good index and a splendid bibliography of some 600 papers (including titles), but even at present-day values its price is much too high.

B. J. Mason

GAS CHROMATOGRAPHY

By N. H. RAY
Research Department, Alkali Division, Imperial Chemical Industries, Ltd.

ONE of the most outstanding advances in analytical chemistry in recent years has been the development of gas chromatography. Realization of the great power and versatility of this technique has resulted in a very high rate of progress, and it is already becoming difficult to keep abreast of all the publications in the field. The intention of the present article is to give a general outline of the methods used in gas chromatography, and to indicate the types of problem for which it is most useful.

Gas chromatography is a method of separating mixtures of gases or volatile liquids by causing them to traverse a column packed with absorbent, in which repeated distribution occurs between the moving gas phase and the stationary phase, which can be either solid or liquid.

Since the moving phase, being a gas, has a low viscosity, it is quite feasible to use very long columns (often up to 12 ft.); and because diffusion in the moving phase is rapid, high rates of flow may be used without loss of efficiency. It is therefore possible in a reasonable time to achieve separations which would require many hours by any alternative method, such as fractional distillation.

For the purpose of discussion, it is convenient to divide gas chromatographic columns into two types: adsorption columns, in which the stationary phase is a solid such as active charcoal; and partition columns, in which the stationary phase is a comparatively involatile liquid, such as a silicone oil, supported on a porous material such as kieselguhr. In both types of column the moving phase is an inert gas, usually nitrogen, which carries the sample to be analysed into and through the column in the form of gas or vapour. Connected to the outlet of the column is a device, such as a thermal conductivity gauge, which can be made to indicate or record the concentration of the constituents of the sample in the exit gas.

The volume of carrier gas which has to be passed through the column to elute each substance in the chromatogram is referred to as the retention volume of the substance; as in liquid chromatography, this is characteristic of the substance in a given column at a given temperature, and provides a method of identification.

Adsorption Columns

The materials employed for the stationary phase in gas adsorption columns are strong adsorbents like charcoal and silica gel. Because the majority of gases and vapours exhibit curved adsorption isotherms on these adsorbents, the straightforward elution of samples from an adsorption column results in the production of unsymmetrical zones, in which usually the leading edge is sharply defined and the trailing edge diffuse. This effect is the more serious, the more strongly adsorbed the substance, and the longer the column (Fig. 1). For this reason, accurate quantitative analysis by this method is only feasible with short columns, or when the substance concerned has a small retention volume, so that the amount of material in the tail of the zone is small enough to be neglected. In spite of this, straightforward elution from a column of adsorbent has been used with considerable success in the analysis of gas mixtures containing hydrogen, nitrogen, carbon monoxide and the lower paraffins[1]; mixtures of paraffins and olefines as far as butane[2]; and mixtures of hydrogen, methane and nitrous oxide[3].

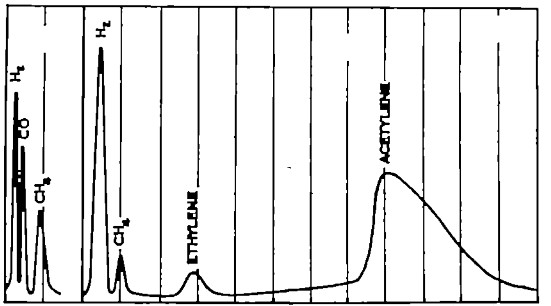

Fig. 1. Elution of gas mixtures from charcoal. (Reproduced by courtesy of the *Journal of Applied Chemistry*)

The accuracy of quantitative analysis by the elution method cannot be improved by increasing the sample size beyond certain limits, due to overlapping of the zones of the chromatogram; for the same reason, the method is unsuitable for detecting a small amount of an impurity in a gas unless there is a big difference between their retention volumes. Much greater accuracy can be achieved, and very low concentrations of impurities can be detected by the use of the displacement technique which was introduced by Claesson in 1946[4]. In this method, which is only applicable to adsorption columns, the constituents of the sample are displaced successively from the column by means of a displacer vapour, which is carried on to the column continuously at constant concentration in the carrier gas stream. The substance chosen for the displacer must be more strongly adsorbed by the packing than any of the components of the sample.

In this type of chromatogram, each substance or group of substances occupying one zone is displaced from the adsorbent at constant concentration by the next more strongly adsorbed substance, and the most strongly adsorbed component is displaced by the displacer. The resulting chromatogram consists of a series of steps, the heights of which correspond to the concentration of material in each zone, which is constant under the conditions of a displacement chromatogram; while the lengths of the steps are proportional to the amount of each substance present (Fig. 2). Increasing the amount of sample does not increase the amount of overlap between adjacent zones in this type of chromatogram and very high quantitative accuracy can be achieved. Even trace amounts of impurities in a gas can be detected in this way by running a large enough sample through a sufficiently long column[5], but the time required for the analysis is increased proportionately.

By combining adsorption chromatography with a chemical absorbent, it is possible to reduce consider-

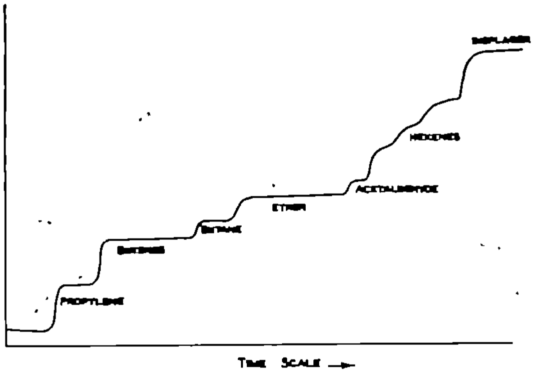

Fig. 2. Resolution of a mixture by displacement analysis from a charcoal mixture

ably the time required for the measurement of trace impurities; if a suitable reagent can be found that will preferentially remove the major constituent of the sample, the residual gases can then be separated and measured on a very much shorter column. The determination of saturated impurities in ethylene has been accomplished in this way, using bromine supported on charcoal to absorb the ethylene[6].

Partition Columns

In a partition column, the absorbent is a liquid, which can often be specially chosen to suit the particular separation it is intended to carry out. Subject to the over-riding consideration that the chosen liquid must have a negligible vapour pressure at the temperature employed (normally a temperature close to the boiling point of the most volatile constituent of the sample), there is a wide variety of liquids which can be used: liquid paraffin, silicone oil, glycerol, and esters of high boiling point, such as dinonyl phthalate, have all been used for a large number of separations. For special purposes the properties of the stationary phase can often be modified advantageously by the inclusion of a solute; for example, in the separation of a series of fatty acids, a 10 per cent solution of stearic acid in silicone oil has proved very successful[7]; and the separation of paraffins from olefins can be greatly improved by taking advantage of the specific interaction between silver ions and the double bond, using as stationary phase a solution of silver nitrate in glycol[8].

The selected liquid is held in the column by supporting it on a porous solid. Originally kieselguhr was used for this purpose, and it is still one of the most popular supports; it is capable of holding up to 30–40 per cent by weight of liquid phase.

More recently a powdered furnace brick ('Sterchamol') has been employed with considerable success[9]; it is coarser than kieselguhr, and the pressure drop through it is lower for a given gas-flow rate. At very high temperatures, salt has been used as the support for the stationary phase[10].

The solid support is impregnated with the liquid absorbent by thorough mixing, which can generally be facilitated by diluting the liquid with a volatile solvent and afterwards evaporating the latter from the paste; the result should be a reasonably free-flowing powder. This is packed as uniformly as possible into the column, which for best results should consist of long straight tubes joined together to form a compact U or W shape (Fig. 3). It is necessary to heat the column to an appropriate temperature for each analysis; this is usually a temperature close to the boiling point of the most volatile constituent of the sample, although satisfactory analyses can be carried out at temperatures much higher than this, as, for example, in the analysis of mixtures of normally gaseous hydrocarbons in a column at room temperature[3]. Since retention volumes in a partition column are very sensitive to temperature, it is important to control the temperature precisely, and for this reason it is a common practice in laboratory work to use vapour jackets for heating; however, most commercially manufactured instruments use electrical heating controlled by a thermostat.

The sample to be analysed may be introduced on to the column either as a liquid or as a gas. The introduction of liquid samples is very conveniently carried out by means of a micrometer syringe, the hypodermic needle being inserted through a rubber serum cap at the beginning of the column. Gas samples may be introduced in a similar manner with the aid of ordinary 5- or 10-ml. hypodermic syringes with well-greased pistons; but greater precision in measuring the sample may be obtained by the use of a short tube of known volume, connected to the column, which can be swept through by the sample and then by the carrier gas, by an arrangement of three-way taps. The small size of the sample (0·5–10 microlitres of liquid, or 1–10 ml. of gas) makes it rather difficult to introduce an exactly predetermined amount, and for this reason internal standards are sometimes employed.

The chromatogram produced on a partition column consists of a series of peaks, which ideally should be symmetrical and similar in shape to a normal error curve (Fig. 4). The position of each peak in the chromatogram is characteristic of the substance concerned in a given column at a fixed temperature, and the constituents of an unknown mixture can be identified by comparison of their retention volumes with those of known compounds on the same column; by the use of two or more columns with different stationary liquid phases, the identification of unknown compounds can be greatly simplified[11].

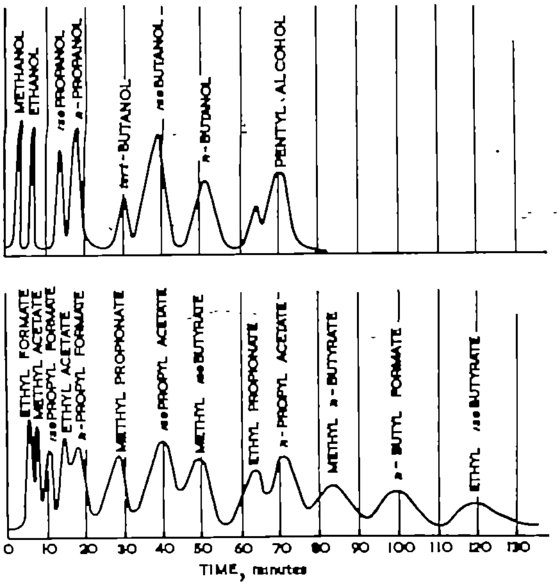

Fig. 4. Resolution of mixtures on a partition column. (Reproduced by courtesy of the *Journal of Applied Chemistry*)

The total area under each peak is proportional to the quantity of the substance present, which can thus be estimated by any of the usual methods. Since in many cases, particularly at the beginning of the chromatogram, the peaks are very narrow, it is often sufficient to measure peak heights; calibration is carried out with known quantities of the substance in question under similar conditions, and an average reproducibility of the order of 1 per cent may be expected in favourable circumstances. A very wide range of compounds can be analysed by gas partition chromatography; the method has been successfully employed for the separation and estimation of hydrocarbons, both aliphatic and aromatic[12], halogenated hydrocarbons[13], including fluorinated compounds[14], alcohols, esters, fatty acids[7], amines and pyridine homologues[11].

Detectors for Gas Chromatography

In both gas adsorption and gas partition chromatography it is necessary to have at the exit of the column a device which is capable of indicating or recording the concentration of the substances present in the chromatogram. A number of such devices have been developed; the earliest, used for the estimation of volatile fatty acids, was the automatic titration cell designed by James and Martin[7]. This detector is of limited applicability, but being an integrating device it possesses advantages over the more usual differential type in quantitative work. Probably the most popular detectors are hot-wire thermal conductivity cells; these are usually employed in pairs, and measure the difference in thermal conductivity between the carrier gas and the column exit gas, so as to compensate to some extent for variations in flow rate. Thermal conductivity cells based on thermistors are used in one of the commercially available instruments for gas chromatographic analysis[15].

The thermal conductivity detector is not sufficiently sensitive for the accurate measurement of minor constituents of mixtures without overloading the column with sample, and a number of other detectors have been developed with the object of providing increased sensitivity. The gas density balance designed by James and Martin[16] responds to minute changes in the density of the column exit gas, and is considerably more sensitive than a thermal conductivity cell; it is somewhat more difficult to construct, however, and is also sensitive to temperature fluctuations. This detector is also available in a commercial gas chromatographic analysis apparatus[17]. The hydrogen flame detector of Scott[18] depends upon the use of hydrogen as the carrier gas; the gas issuing from the column is burnt at a jet, and just above the tip of the flame is placed a thermocouple. The presence of organic compounds in the gas increases the height of the flame, which engulfs the thermocouple. The response is linear over a wide range, and the detector is particularly suitable for the analysis of hydrocarbons, since their heats of combustion per unit weight are all very similar, and thus a single calibration can be used. There are two detectors which depend upon ionization of the column exit gas; in one of these, due to Boer[19], a capsule of radioactive strontium is used to ionize the gas by β-ray emission; a potential is applied between two electrodes in the gas and the ionization current is measured. In the other, due to Ryce and Bryce[20], a portion of the column exit gas is passed through a thermionic ionization gauge and the resulting current is measured. By using for the carrier a gas such as helium, which has a very high ionization potential, it is possible to achieve extremely high sensitivity with this device.

Conclusion

Gas chromatography is a relatively simple process to carry out, yet it provides rapid and efficient separations of a very wide range of compounds. By the use of columns running at high temperatures, even substances with very low vapour pressures can be separated and determined, provided they are sufficiently stable to heat. For analytical purposes, only very small samples are required, and if necessary the sample can be recovered after the analysis; on a preparative scale, large columns are needed, but it is feasible to construct apparatus to deal with amounts up to 10 gm. Finally, it should also be pointed out that gas chromatography is potentially a very powerful tool in physical chemistry, where it can be used for the determination of distribution functions and adsorption isotherms.

AN EXPERIMENT ON AIR SHOWERS PRODUCED BY HIGH-ENERGY COSMIC RAYS*

By Drs. G. CLARK, J. EARL, W. KRAUSHAAR, J. LINSLEY, B. ROSSI and F. SCHERB

Department of Physics and Laboratory for Nuclear Science, Massachusetts Institute of Technology,
Cambridge, Massachusetts

Size, Spectrum and Atmospheric Absorption

The quantities of interest here are best described in terms of the functions $S(N,x)$ and $N(E,x)$. $S(N,x)$ is the 'integral size spectrum' of all showers observed at the atmospheric depth x; in other words, $S(N,x)$ $A\,d\omega$ is the number per unit time of showers with more than N particles the axes of which lie within the solid angle $d\omega$ and intersect perpendicularly the area A. $N(E,x)$ represents the number of particles in a shower that develops from a primary particle of energy E through a thickness x g cm.$^{-2}$ of atmosphere. In our discussion we neglect fluctuations, and represent the development of all showers by their average behaviour. To our knowledge a satisfactory treatment of the fluctuation problem is still lacking.

The atmospheric thickness x is measured in the direction of the shower axis; thus for a shower coming at the zenith angle θ, x is related to the vertical depth x_0 by the equation: $x = x_0/\cos\theta$. We assume that N depends on the atmospheric thickness x thus defined, but does not depend explicitly on θ; that is, we assume that for a given total mass of air traversed, N is independent of the distribution of the air density along the path of the shower. This assumption appears to be well justified even though it is not rigorously correct, because the density distribution has an effect on the contribution of unstable particles to the development of the shower.

From our experimental results we wish to determine (a) the dependence of S on N at x, and (b) the dependence of N on x. The analysis is complicated by the fact that if we wish to make full use of the experimental information, we cannot treat problems (a) and (b) separately. However, it turns out that we need only an approximate knowledge of the dependence of N on x to determine accurately the size spectrum $S(N,x)$. Thus we can proceed by successive approximations.

For a preliminary analysis of the results we assume that N depends exponentially on x:

$$N(E,x) = N(E,x_0)\exp\left(-\frac{x-x_0}{\lambda}\right) \qquad (2)$$

where λ is a constant; we assume further a power-law dependence of S on N:

$$S(N,x) = \left(\frac{N_0}{N}\right)^{\gamma} S(N_0,x) \qquad (3)$$

where N_0 is some convenient reference size.

On these assumptions it can be shown that:

(a) S is also an exponential function of x so that:

$$S(N,x) = \frac{K}{N^{\gamma}}\exp\left(-\frac{x-x_0}{\Lambda}\right) \qquad (4)$$

where K and Λ are constants;

(b) λ, Λ and γ are related by the equation:

$$\Lambda = \lambda/\gamma \qquad (5)$$

(c) The size spectrum of showers coming from all directions (and therefore corresponding to different values of x) is represented by a power law with the same exponent γ which characterizes $S(N,x)$.

It then follows that we can determine the exponent γ from the number-size distribution of all showers, and the thickness Λ, which characterizes the dependence of S on x, from the dependence on the zenith angle. Using equation 5, we can then compute a preliminary value of λ.

For the final determination of the spectrum, we proceed as follows. Using the approximately known value of λ, we compute the equivalent vertical size $N(x_0)$ of each observed shower, namely, the number of particles which would have been present in the shower had it come from the vertical direction. Since most showers come from small zenith angles, and since, in any event, we disregard showers with zenith angles greater than 30°, the overall result is not sensitive to the exact value of λ. Having reduced all showers to equivalent vertical sizes, and having computed for each equivalent vertical size the effective solid angle and the effective area of detection, we can construct the size spectrum at x_0 with an accuracy which is essentially limited only by statistical fluctuations and by the instrumental errors in the determination of N.

Figs. 8 and 9 summarize the results obtained from a partial analysis of the observations collected in the course of three consecutive experiments, characterized by different selection criteria (No. 1: more than 17 particles in three or more of detectors C, E, M; No. 2, same for detectors C, M, D; No. 3: same for detectors C. D: see Fig. 1).

Fig. 8 is obtained from the observations on the dependence of zenith angle of showers observed in experiments Nos. 1 and 2. The abscissa represents the difference between the atmospheric depth $x = x_0/\cos\theta$ and the vertical depth at sea-level x_0. The ordinate is the logarithm of the number of showers for which x lies between x and $x + \Delta x$, divided by the solid angle corresponding to the depth interval Δx. Within the statistical errors, the experimental points corresponding to the two experiments lie on straight and nearly parallel lines. This confirms the approximately exponential dependence of S on Λ (equation 4). Moreover, since the mean sizes of showers in the two groups of observations differ from one another by a factor of about 10, we conclude that the characteristic thickness Λ does not change rapidly with N. For the purpose of further analysis we take for Λ the value: $\Lambda = 95$ gm. cm.$^{-2}$. This selection is based both on our results and on the results on the altitude variations and barometric coefficients of air showers obtained in other experiments[2].

---

* Continued from p. 356.

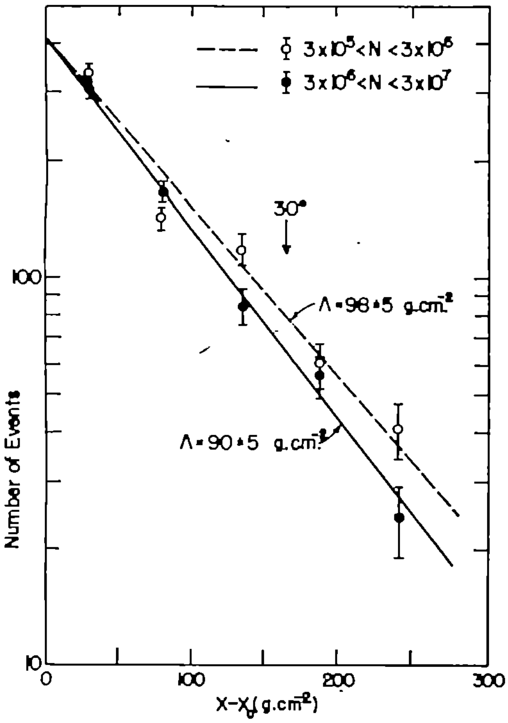

Fig. 8. Plot of observations on the atmospheric attenuation of showers obtained from the distribution of zenith angle

A preliminary analysis of the shower size distribution yields $\gamma = 2$. Thus, for the conversion of showers to equivalent vertical sizes, we use $\lambda = 190$ gm. cm.$^{-2}$. The estimated uncertainty in this value amounts to about 30 gm. cm.$^{-2}$.

Fig. 9 summarizes our present results on the size spectrum as obtained from a combination of the data supplied by the three experiments mentioned above. An important step of the analysis is the precise definition of an 'acceptance area' for showers of each size. This area is chosen so as to ensure that any shower the centre of which lies within its boundaries has practically 100 per cent probability of triggering the recording system. The results are presented in the form of a differential spectrum. The abscissa is the logarithm of N, and the ordinate is the logarithm of $s(N,x_0)$, where $s(N,x_0) = \dfrac{\partial S(N,x_0)}{\partial N}$. (The actual plot was made as follows. For each vertical shower size we computed a weight factor W representing the reciprocal product of the effective solid angle and effective area of detection. We then divided the abscissa N into equal logarithmic intervals. For each interval, ranging from N_1 to N_2, we computed the sum of the quantities W relative to all observed showers falling within this interval, and divided this sum by $N_2 - N_1$. We took this quantity to represent $s(N)$. We choose the corresponding abscissa, $\overline{N}$, to satisfy the equation: $\dfrac{1}{\overline{N}^{\gamma}} = \dfrac{1}{N_2 - N_1} \displaystyle\int_{N_1}^{N_2} \dfrac{dN}{N^{\gamma}}$.)

The quantity $\dfrac{\partial S(N,x_0)}{\partial N}$ represents the rate of arrival (per cm.^{2} and steradian in the vertical direction) of showers with N particles. We see that within the limits $10^6 < N < 10^8$ the differential spectrum may be closely approximated by a power function of N, with a negative exponent of 2·84 ± 0·15. The corresponding integral spectrum is represented by the equation:

$$S(N,x_0) = (3{\cdot}8 \pm 1{\cdot}2) \times 10^{-13} \left(\frac{10^6}{N}\right)^{1.84} \text{cm.}^{-2}\,\text{sec.}^{-1}\,\text{str.}^{-1} \quad (6)$$

This result agrees satisfactorily with our preliminary estimate of the shape of the spectrum.

The intensity given by equation 6 for $N = 10^6$ agrees reasonably well with the value of $5{\cdot}5 \times 10^{-13}$ cm.$^{-2}$ sec.$^{-1}$ str.$^{-1}$ found by Greisen from a detailed analysis of measurements of the density spectrum of showers[3] (that is, the rate at which a detector records a local density of shower particles exceeding a given value). However, the size spectrum obtained from an observed density spectrum is reasonably accurate only if (1) the shape of the lateral distribution function at small distances from the shower core does not change with shower size, and (2) the size spectrum can be represented by a power law with a very slowly varying exponent. The observed form of the density spectrum will not reveal the details of any sudden deviation of the size spectrum from such a power law. The present experiment with its good size resolution indicates the absence of any deviations up to $N = 10^8$ particles.

Energy Spectrum of Primary Cosmic Ray Particles

We probably have not introduced serious errors into the analysis of the results for the size spectrum by neglecting the effect of fluctuations in shower development. On the other hand, the proper conversion of the size spectrum into a primary energy spectrum would require a careful consideration of fluctuations. For the time being, however, we shall

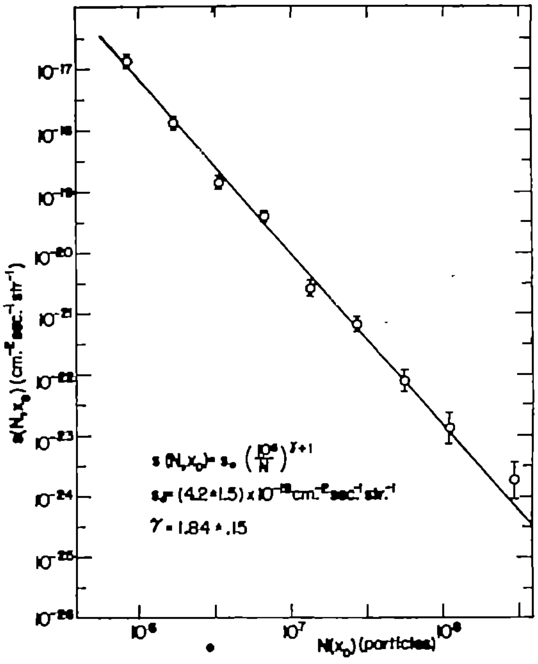

Fig. 9. Differential size spectrum of showers at sea-level in the vertical direction

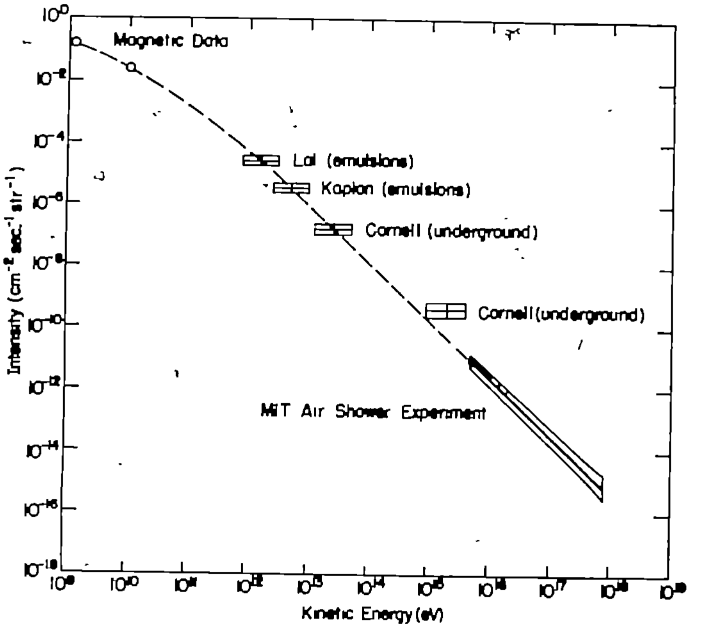

Fig. 10. Plot of the combined results from several experiments on the integral energy spectrum of primary cosmic rays

neglect fluctuations, with the realization that this neglect may lead to a systematic error in the evaluation of the primary intensity, and will smear the details of any sudden changes in the primary spectrum that may exist.

S. Olbert has computed the function $N(E,x_0)$ using both the Fermi and the Landau models of high-energy nuclear interactions[4]. Assuming complete inelasticity and a collision mean free path of 100 gm. cm.$^{-2}$, he has obtained:

according to Fermi's model:

$$N = 1{\cdot}80 \times 10^{5} (E/10^{15})^{1{\cdot}10} \qquad (7)$$

according to Landau's model:

$$N = 1{\cdot}10 \times 10^{5} (E/10^{15})^{1{\cdot}16} \qquad (8)$$

We see that the relationship between N and E is relatively insensitive to the particular model. Hence the computation of primary energies is not subject to a large uncertainty on account of our incomplete understanding of high-energy nuclear interactions.

Using equation 8 based on Landau's model, we obtain from equation 6 the following expression for the integral energy spectrum, $J(E)$, in the range 4×10^{15} eV. $< E < 10^{18}$ eV.:

$$J(E) = 2{\cdot}2 \times 10^{-10} (10^{15}/E)^{1{\cdot}18} \text{ cm.}^{-2} \text{ sec.}^{-1} \text{ str.}^{-1} \qquad (9)$$

Fig. 10 shows the portion of the integral energy spectrum obtained from the present experiment together with the results at lower energies collected by the Cornell Group[6].

The fact that the cosmic-ray spectrum extends without sign of a break to about 10^{18} eV. places any strictly galactic theory of the origin of cosmic rays under severe strain. Indeed, if we accept the conventional description of the galaxy as a disk about 1,000 light years thick, with an interstellar magnetic field of the order of 5×10^{-6} gauss, we conclude that protons of 10^{18} eV. travel along trajectories with a mean radius of curvature of the order of the thickness of the disk, and thus must escape from the galaxy quite freely. It follows that a galactic acceleration mechanism of the kind suggested by Fermi, which requires times of the order of millions of years to double the energy of the particles, cannot produce protons of energies approaching 10^{18} eV. Moreover, even if we grant the existence of suitable galactic sources of such high-energy particles, we would still be faced with the difficulty of explaining why the energy spectrum does not drop sharply when trapping by the galactic magnetic field ceases to be effective.

Of course, we cannot discount the possibility that large showers may be produced by heavy nuclei, the magnetic rigidity of which is smaller than that of protons of the same energy by a factor equal to the nuclear charge. Even so, however, it begins to appear that some modification of the conventional views regarding the structure of the galaxy and the conditions of space outside the galactic disk may become necessary. The least drastic revision would be the assumption of a nearly spherical galactic halo of highly turbulent diluted gas carrying magnetic fields not much weaker than those existing in the galactic disk. This halo (for which there seems to be some astronomical evidence) would then replace the galactic disk as the confining volume for cosmic rays. Cosmic ray particles, escaping from the disk, could be brought back to it perhaps after having gained most of their energy while travelling through the halo.

The above considerations clearly indicate the crucial importance of further experiments. It will be particularly interesting to see whether or not the anisotropy at the highest energies which our preliminary results suggest will be confirmed. What is known about the magnetic field of the galaxy seems to indicate that this field has an irregular local structure but follows a fairly regular pattern in its average distribution. Hence even in the presence of a galactic halo, particles with trajectories insensitive to the small-scale irregularities of the field might exhibit some anisotropy related in a simple manner to the location of the sources and to the large-scale structure of the field. Also the spectrum should not extend much beyond 10^{18} eV. without a marked change in its logarithmic slope.

If this change does not occur, and if isotropy subsists well beyond 10^{18} eV., we may be forced into the assumption of an extragalactic origin of high-energy cosmic rays. This assumption would not be unacceptable on energy grounds, for the high-energy tail of the cosmic-ray spectrum carries only a very small fraction of the total cosmic-ray energy. However, it might be taken as an indication of the existence in intergalactic space of variable magnetic fields capable of accelerating cosmic-ray particles.

We acknowledge the essential contributions made by P. Bassi and M. Oda to the early planning and

development of this experiment. Many others associated with the Massachusetts Institute of Technology have given us their generous co-operation. We wish particularly to thank Harvard University and the staff of the Harvard College Observatory for making it possible for us to carry out the experimental observations on the grounds of the George R. Agassiz Station.

This work has been supported in part by the joint programme of the Office of Naval Research and the Atomic Energy Commission, and in part by the National Science Foundation.

---

[4] Part of Olbert's theory will appear soon in *Annals of Physics*. We are greatly indebted to Dr. Olbert for making his unpublished results available to us.

UNIVERSITY COLLEGE OF RHODESIA AND NYASALAND

INSTALLATION OF THE QUEEN MOTHER AS PRESIDENT

ON the morning of July 5, almost four years after H.M. Queen Elizabeth the Queen Mother had laid the foundation stone of the University College of Rhodesia and Nyasaland, she was installed as its first president at a ceremony held in the College amphitheatre. The plans for, and the development of this College, situated in Salisbury, Southern Rhodesia, and by its charter of a multi-racial character, have been referred to in the columns of *Nature* from time to time (*Nature*, 172, 1 (1953); 173, 1007 (1954); 175, 181 (1955); 179, 612 (1957)). This important new venture received a most significant stimulus when Her Majesty accepted the post of first president of the College.

In her speech after installation, the Queen Mother referred to the setting up of a university institution in this part of Africa, which had been in contact with Western civilization for so short a time, as "a striking act of faith". In her own words, "To insist that the College from its inception should aim at the highest academic standards and should open its doors to all who are qualified to enter, regardless of race or colour, is a great challenge. I am persuaded, however, that this act of faith will be justified and this challenge successfully met because the College, by the very boldness of its conception, is in the pioneering tradition of this country—a tradition of which the supreme example is the life and service of Cecil Rhodes".

The College early took the decision to embrace special relationship with the University of London (see *Nature*, 175, 181; 1955), and so the degrees to be taken by the undergraduates of the University College will be those of the University of London. In her speech at her installation, Her Majesty, who is both president of the College and chancellor of the University of London, was therefore able to say: "The Chancellor of the University of London is delighted to be able to inform publicly the President of the University College of Rhodesia and Nyasaland that the special relationship which exists between the two institutions is 'Twice blest, It blesseth him that gives and him that takes'."

At the installation ceremony there were present representatives of fifteen universities of the United Kingdom, in addition to twenty-four from other parts of the Commonwealth. Fourteen universities and colleges in other parts of the world were also represented, including eight from the United States of America. Many of the representatives presented addresses of congratulation to the Queen Mother as president of the College on behalf of their university institutions. The universities in the Union of South Africa have naturally been especially interested in the development of a multi-racial university college in a territory so close to their own and, as the Queen Mother pointed out in her address, it was an imaginative and graceful gesture on the part of the University of Cape Town to present to the University College of Rhodesia and Nyasaland the presidential robes which she wore on the occasion of her installation. The Queen Mother asked that the representative of the University of Cape Town, its chancellor, the Hon. Albert van de Sandt Centlivres, would take back to his colleagues a message of grateful thanks from the College.

The University College of Rhodesia and Nyasaland stands on rising ground, three to four miles to the north of the centre of the city of Salisbury in an area known as Mount Pleasant. The area of the site is 474 acres and it was given by the City of Salisbury for the purpose. The general layout of the University buildings was prepared after consultation in 1954 with Sir William Holford, and afterwards the buildings have been planned by one or other of three firms of architects. At the present time one wing of the Arts building has been erected and contains a large entrance hall, classrooms and a lecture theatre. It also houses rooms for the teaching staff, senior common room, administrative offices and the council room. Nearby, two buildings provide initial accommodation for the science departments, one housing the Departments of Botany and Zoology, the botanical garden and the vivarium being immediately adjacent, while another will provide permanent housing for the Departments of Chemistry and Physics. The third will be that accommodating the agricultural laboratories.

The first portions of three halls of residence have already been built, grouped around a park in the residential area of the site. All three are designed on the same pattern and when complete will accommodate 120 students each. To each will be attached a warden's house, dining hall, kitchen and common room. Individual study–bedrooms are arranged in corridors of eight, each of which ends in a sitting room and balcony. At the time of the installation ceremony, the dining room in only one of the halls was in operation, and in this all the undergraduates were taking their meals together. The design of the buildings so far erected is modern without stridency. Functional forms have been softened in a manner which allows them to sink effectively into the background in which they are built.

In the north-west corner of the site lies a large quarry which, by a happy inspiration, has been converted into an open-air amphitheatre, seating more than three thousand people, for ceremonies, concerts and theatrical performances, and it was here that the installation of the Queen Mother took place. Those who were responsible for the planning of this are to be congratulated.

Of the seventy full-time students at the College in July 1957, fourteen are members of the Faculty of Science, taking the B.Sc. (General) course in science of the University of London. Fifty-four of the students are resident; eight, including one woman, are African and there is one Indian woman student who is non-resident. Of the subjects coming under the Faculty of Science, chemistry is the most frequently studied, having about twice as many students as other subjects. Botany, mathematics, physics and zoology enrol approximately the same numbers.

Of the nine professors who have at present taken up their appointments, five are in the Faculty of Science, three are in the Faculty of Arts (African studies, English and education), while a special appointment as director of the Institute of Education is held by Prof. B. A. Fletcher. The library, which already contains nearly 16,000 volumes, is regularly receiving 450 journals.

As has been said more than once, in a country where racial tension can arise, the position of a multi-racial university is especially important. The declared aim of the Central African Federation is a partnership between the races, European and non-European, and to the attainment of this ideal the University College of Rhodesia and Nyasaland, with the goodwill of the people and Government support, will make a most important contribution. In the words of the motto of the University College, 'Wisdom builds the house of life'. Wisdom has indeed gone to the founding and fostering of this new University institution, and to the principal, Dr. Walter Adams, and to all his staff, universities all over the world will look for the results of a most important educational experiment during the coming years.

F. G. Young

OBITUARIES

Dr. Harold Thompson

Only a few of the ex-Servicemen who entered fishery research in 1920 had survived as soldiers from the beginning of the war-period 1914–18, and among them was Capt. Harold Thompson, of the Royal Field Artillery, who had served five years in France and had twice been mentioned in dispatches. His first fishery research was on the great number of haddock scales collected by the Scottish research vessels. They made very good sense when handled by Thompson, who was soon able to forecast with some accuracy the fortunes of the important North Sea haddock fishery. The basis was the relative abundance of annual broods of fish, as shown by catches of ages below those at which they exerted their full commercial weight. Thompson's success convinced us all that the Norwegian methods need not be confined to their own fisheries, where extreme annual fluctuations were the rule, and forecasting became, after Thompson's work, one of the standard aims of fishery research everywhere.

Harold Thompson was born on October 12, 1890. He was the son of William Thompson, who was headmaster of the Middle School, Aberdeen. After graduating in arts in 1912, he taught for one year in Perthshire and returned to the University of Aberdeen with the intention of taking a science degree. On the outbreak of war, however, he enlisted in the Gordon Highlanders and was later promoted to commissioned rank in the artillery.

In 1920 Thompson obtained special distinction in chemistry and zoology for his B.Sc. degree at Aberdeen and, after a short period assisting in the Biochemistry Department in the University of Edinburgh, was appointed a junior naturalist by the Fishery Board of Scotland in 1921. His doctorate was awarded for a thesis on the local growth-rates, age analyses and migrations of the haddock. He did not, however, relinquish his interest in systematic zoology. Although he was to carry for most of his working life the responsibility of a director, he yet found time to make substantial additions to knowledge of the tunicates.

For some years the Government of Newfoundland, then proudly calling itself Britain's oldest Dominion, had been anxious to know more about the fish on which the economy of the island mainly depended. In 1930 Thompson undertook a survey of the fisheries, and in 1931 he was made the first director of fisheries research in Newfoundland. He built up an organization based on Bay Bulls near St. John's and used a trawler for research purposes, making not only the usual ecological surveys but also attempting some codification of the undoubted relationship between cod catches and temperature, which had been explored first by Commandant Beaugé of the French Fisheries Service. Thompson gave, with due reservations, something of a guide to favourable temperatures in different regions and for different sizes of cod, and this provided a basis for more recent work in other parts of the world where there is mixing of Arctic and Atlantic water. Sometimes the relationship is as it were accidental, depending really on the movement of the water-masses; sometimes it is vital, and I think that Thompson fully realized both possibilities.

In 1937 Thompson was again to found a new fisheries laboratory, this time at Cronulla, near Sydney, with subsidiary stations in other parts of Australia. He attracted and selected staffs of high quality, and a substantial bulk of excellent work has come from his foundations. He retired from the post of chief of fishery investigations in December 1954, and the library at Cronulla is named after him.

In appearance, Thompson was spare, dark and keen looking. He looked what he was—penetrating, critical and reliable. He could not have achieved what he did without a firm intention amounting almost to enthusiasm; but he also gave full measure of scepticism where it was required, and accepted without apparent concern the resulting ingratitude. He engendered the firm respect and affection of those who appreciated his highly tempered quality. Thompson died in Edinburgh on May 29, and leaves a widow and son who will have all our sympathy.

Michael Graham

Mrs. Alice Sophia Cooke

MRS. ALICE SOPHIA COOKE (Mrs. A. S. Bacon), head of the Biology Department of Brighton Technical College during 1920–30, died at her home in Hassocks, Sussex, on May 21. Mrs. Cooke was born in London in 1890. In 1909 she obtained a Drapers' Company scholarship from the City of London School for Girls to the East London College (now Queen Mary College). There, as one of the late Prof. F. E. Fritsch's first students, she took her B.Sc. honours degree in botany in 1912, and was then appointed assistant biology mistress at the Swindon and North Wiltshire Secondary School and Technical Institute. In the following year she went to Huddersfield Technical College as assistant lecturer in biology, and in 1920 was appointed lecturer in biology at Brighton Technical College. Until her arrival at Brighton no systematic teaching in biology was undertaken there, but within five years a number of her students had obtained University of London honours degrees in botany, and the courses for the intermediate, first M.B. and matriculation examination were all well established.

She will be remembered as an inspiring and dedicated teacher who might have achieved great distinction in research. Instead she spared no pains in providing her students with a balanced training in botany in which each branch was introduced with an equally infectious enthusiasm. To her students her standards appeared appallingly high, but they were invariably achieved by a careful blend of admonition and encouragement. Outside the university examination courses she took a great deal of practical interest in her evening classes in horticultural botany for gardeners, and she was also well known for her activities in the educational field, more especially in the teaching of science.

As a field botanist Mrs. Cooke had an unrivalled knowledge of the Sussex flora and had travelled widely both in the British Isles and on the Continent, in the course of which she built up a remarkable collection of botanical material including an extensive bryophyte herbarium, all of which was constantly used in her lecture courses.

She was elected a Fellow of the Linnean Society of London in 1922 and also belonged to the British Bryological Society, the British Ecological Society, the British Mycological Society, the Brighton and Hove Natural History Society and the Freshwater Biological Association.

Mrs. Cooke had great personal charm; she would generously give her time to others, and she followed the subsequent careers of her students with interest. Her influence on botany has been indirect, through her students, and the many botanists, zoologists, pharmacists and others whom she trained have derived immeasurable benefit from the teaching of one of the most able of botanical teachers.

NEWS and VIEWS

Manchester Museum: Mr. R. U. Sayce

MR. R. U. SAYCE, who is shortly retiring from the keepership of the Manchester Museum in the University of Manchester, was appointed to that post in 1935, and since that year has done much to modernize the display. He has had the task of keeping the balance between the two major responsibilities of the Museum, namely, those of making the collections attractive to the public, while at the same time maintaining their value to students from the University. Throughout this period Mr. Sayce has also maintained close co-operation with local learned societies, undertaken much research, published the results of his work, and acted as honorary editor to the *Montgomeryshire Collections* for more than twenty-five years. Throughout he has organized an invigorating schools service, thus bringing an atmosphere of freshness and vitality to the Museum. In 1941 he was president of the north-western Federation of Museums and Art Galleries and in the national sphere was president of Section H at the Brighton meeting of the British Association in 1948. Mr. Sayce has served museums and scholarship with distinction, and in his retirement intends to continue his work in both these interests.

Dr. D. E. Owen

DR. DAVID E. OWEN, who is to succeed Mr. Sayce as keeper of the Manchester Museum, is by training a geologist who has specialized in the administration of museums. Appointed curator in geology at the Public Museum, Liverpool, in 1935, he became director of the City Museum, Leeds, in 1947 and has now completed ten years in that city. While at Leeds he has planned and built a model coal mine, planned two streets of craft workshops at the Abbey House Museum and has recently been responsible for the layout of an instructive Geological Garden. He has always been interested in the relationship of the Museum with the public and has done much to bring museums to the attention of the ordinary individual. In the wider sphere, he has given much voluntary service to the aims and objects of the Museums Association and is now its honorary treasurer. Dr. Owen will thus bring to Manchester a wealth of experience in modern display, a deep conviction of the value of museums and an academic approach which is so essential in a university museum.

Radiation Research Visiting Club

A Radiation Research Visiting Club was formed in 1953 in response to a desire among radiobiologists in Britain to meet one another and to visit each others laboratories. An invitation list was compiled of institutes and laboratories where work is in progress in the field of radiation biology, radiation medicine, radiation physics and radiation chemistry, and to this list was added the names of a number of individuals known to be working in this field but unattached to any of the enrolled laboratories. Four meetings of the Club have been held, and each has been organized entirely by the host institute. At the present time the Club is very informal in nature, there being no elected officers, and the only record kept being the roll of attendance at each meeting.

The number of workers in the field is steadily increasing and a time must come when some host institutes will find it impracticable to invite everyone on the roll to the meetings which they are organizing; but this is regarded as an additional reason for making the existence of the Club as widely known as possible. Intending host institutes would like to inform all interested workers of a particular forthcoming meeting and invite as many as possible of those who indicate a desire to attend. If, therefore, there are workers who do not already receive notices of the meetings of the Radiation Research Visiting Club, either as individuals or through a group with which they are working, but would like to receive such notices, they should inform Dr. L. F. Lamerton at the Physics Department (Downs Branch), Royal Marsden Hospital, Clifton Avenue, Belmont, nr. Sutton, Surrey, where the next meeting of the Club will be held in November.

Animal Health Trust Educational Awards

THE Animal Health Trust awards for the period 1957–58 include the following: *Wellcome Fellowships*: L. F. Taffs (Downing College, Cambridge), to study immune reactions of pigs to worm parasites, particularly *Ascaris lumbricoides*, under Prof. W. I. B. Beveridge at the Department of Animal Pathology, School of Veterinary Medicine, Cambridge; J. S. M. Hutchinson (Nottingham University School of Agriculture), to carry out a quantitative evaluation of changes in gonadotrophin levels in the pituitary gland of the ewe in reproductive states by means of a biological assay in conjunction with cytological studies, under Dr. H. A. Robertson, at the Biochemistry Section, Department of Agricultural Science, University of Nottingham; P. J. McCosker (University Veterinary School, Brisbane, Australia), to study aspects of copper metabolism in bovine blood at the Department of Clinical Studies, Cambridge, under Prof. L. P. Pugh. *Research Training Scholarships*: F. A. Harrison (University of Liverpool), to take an honours course in physiology in the Department of Physiology, University of Liverpool, under Prof. R. A. Gregory; D. F. Kelly (University of Bristol), for further studies in the Department of Pathology, Cambridge, under Prof. H. R. Dean; D. B. Ross (Trinity College, Cambridge), to study the mineral metabolism of sheep with particular reference to mechanisms responsible for homoeostasis, at the Department of Animal Pathology, Cambridge, under Prof. Beveridge.

Physics of Elementary Particles

A SYMPOSIUM on the physics of elementary particles was held during July 15–30 at Buenos Aires and La Plata, Argentina. The symposium was sponsored by Unesco, the Argentine Atomic Energy Commission and the Universities of Buenos Aires and La Plata, and was attended by physicists from Argentina, Brazil, Chile, Bolivia, Uruguay and other South American countries. Dr. B. Cork was invited from Berkeley, California, and Prof. Abdus Salam from the United Kingdom. An attempt was made to survey the entire theoretical and experimental development of elementary particle physics. There were, in addition, a number of original communications from various delegates. The success of the symposium was due to the hospitality of the Argentine Atomic Energy Commission and the efforts of the organizing committee, which consisted of Profs. E. D. Galloni, J. J. Giambiagi, J. G. Roederer, and J. F. Westerkamp.

Conference on the Mechanical Properties of Non-Metallic Brittle Materials

FOR some years the National Coal Board's Mining Research Establishment at Isleworth, Middlesex, has been studying the properties of coal with the view that greater understanding of the material will aid the development of improved techniques for mining and handling it. Parallel work is being started on coal measure rocks in relation to methods of breaking them down, and of controlling the strata around mining excavations. The work includes development of test methods whereby these materials can be classified and described in a way which will guide the mining engineer in his choice of methods of working, and also laboratory studies of breakage under various patterns of applied stress with the object of developing improved mining techniques. A particular difficulty in this work, as in that on other brittle materials, lies in the variability of behaviour necessitating a statistical approach. It is felt that many of the problems are common to research in other substances, road and building materials, for example, or glass and ceramics. It is therefore planned to hold a Conference on the mechanical properties of non-metallic brittle materials at the Mining Research Establishment on April 1 and 2, 1958, with papers by National Coal Board staff and invited contributions from other organizations. The programme, arranged in consultation with the Building Research Station of the Department of Scientific and Industrial Research, includes strength in compression, tension, bending and shear; elastic properties and liability to creep; dynamic and repeated loading including shock waves, crack propagation and the effects of impact; the action of tools including wedge penetration normal and parallel to the surface, friction and abrasion. It is intended to circulate papers in advance and to introduce them very briefly at the Conference so that a maximum proportion of the time can be spent in discussion.

Zoological Nomenclature

THE International Commission on Zoological Nomenclature gives notice that, as from February 26, 1958, it will start voting on the following cases involving the possible use of its plenary powers for the purposes specified against each entry. Full details of these cases were published on August 26 in the *Bulletin of Zoological Nomenclature* (12, Part 12, and 13, Part 8): (1) *parvula* Morch, 1863 (*Aplysia*), validation (Cl. Gastropoda); (2) *Anodonta* Lamarck, 1799, validation (Cl. Pelecypoda); (3) *padi* Linnaeus, 1758 (*Aphis*), validation (Cl. Insecta, Order Hemiptera); (4) and (5) *lineata* Young and Bird, 1828 (*Terebratula*), and *subconcinna* Davidson, 1852 (*Rhynchonella*), interpretation (Cl. Brachiopoda); (6) *anonyma* Lewis, 1872 (*Liminitis*), suppression (Cl. Insecta, Order Lepidoptera); (7) *obtusa* Montagu, 1803 (*Bulla*), validation (Cl. Gastropoda). A proposal is also made for the adoption of a declaration clarifying the status of adjectival specific names consisting of partly Latinized words. Comments should be sent as soon as possible in duplicate to Francis Hemming, Secretary to the Commission, 28 Park Village East, Regent's Park, London, N.W.1.

Oversea Service Division, Colonial Office

The following appointments have recently been made in the Oversea Service Division, Colonial Office: E. C. Clarke (assistant conservator of forests, class 2, Cyprus), assistant conservator of forests, class 1, Cyprus; D. Moore (deputy conservator of forests, Trinidad), conservator of forests, Trinidad; J. C. Mouskos (administrative officer, class 2, Cyprus), assistant conservator of forests, class 1, Cyprus; D. Jones (meteorologist, grade 1, Federation of Nigeria), senior meteorologist, Federation of Nigeria; R. H. Williams (deputy chief surveyor, Federation of Malaya), chief surveyor, grade 2, Federation of Malaya; W. N. Scott (assistant director of Veterinary Services, Uganda), deputy director, East African Trypanosomiasis Research Organization, East Africa High Commission; E. K. Clarke, agricultural officer, Nyasaland; D. M. Hill, agricultural officer, Nyasaland; J. P. Law, agricultural officer, Sierra Leone; N. Le Poidevin, agricultural officer, Gambia; D. McDonald, plant pathologist, Northern Region, Nigeria; C. K. H. Martini, plant pathologist, West African Cacao Research Institute, Western Region, Nigeria; T. G. Moffatt, agricultural officer, Northern Region, Nigeria; R. Orpin, agricultural officer, Nyasaland; D. J. H. Thomas, agricultural officer, Western Region, Nigeria; J. M. S. Burgess, assistant conservator of forests, Nyasaland; E. W. Gregor, assistant conservator of forests, Somaliland Protectorate; D. B. Webb, assistant conservator of forests, British Honduras; J. F. Bateson, geologist, Seychelles; W. E. Evans, geologist, Cyprus; T. A. Moore, geologist, Cyprus; R. D. Morris, geologist, Cyprus; A. F. Fraser, veterinary officer, Jamaica; G. D. Harris, veterinary officer, Northern Region, Nigeria.

The appointment of J. H. Hill was as geologist, British Solomon Islands Protectorate (and not Fiji, as printed in *Nature* of June 15, p. 1225).

The Night Sky in September

Full moon occurs on September 9d. 04h. 55m. U.T., and new moon on September 23d. 19h. 18m. The following conjunctions with the Moon take place: September 1d. 04h., Saturn 0·6° S.; September 26d. 18h., Venus 2° S.; September 28d. 14h., Saturn 1° S. In addition to these conjunctions with the Moon, Saturn is in conjunction with Antares on September 6d. 06h., Saturn being 6·2° N., and Venus with Spica on September 7d. 22h., Venus being 2·1° N. Mercury will be visible as a morning star during the last week of September, rising at 4h. 30m. on September 30. Venus sets about an hour after the Sun, and will be visible as a bright object low in the west just after sunset. Mars and Jupiter are too close to the Sun for observation. Saturn sets at 21h. 55m., 21h. 00m., and 20h. 05m. on September 1, 15 and 30, respectively; it is moving eastwards in Ophiuchus, being north of Antares. Saturn has stellar magnitude + 0·8 and a distance on September 15 of 950 million miles. There is one occultation of a star brighter than magnitude 6, observation being made at Greenwich: September 21d. 3h. 48·8m., ω Leo. m. (*R*). *R* refers to reappearance. There is a daylight occultation of Saturn on September 28, visible at Greenwich. Disappearance is at 12h. 47·7m., reappearance at 13h. 44·9m. The autumnal equinox occurs on September 23d. 07h.

Announcements

Dr. Martin H. Moynihan, who graduated at Princeton and carried out postgraduate studies at Oxford, has been appointed resident naturalist of the Smithsonian Institution's Panama Canal Zone Biological Area, a tropical forest and wild-life preserve on Barro Colorado Island in Gatun Lake, Canal Zone.

Mr. R. D. Johnston has been awarded a fellowship for postgraduate research in the Department of Metallurgy at Battersea College of Technology, London, by the British Oxygen Co., Ltd.

Applications for grants from the Research Fund of the Chemical Society for the assistance of research in all branches of chemistry should be submitted on the appropriate form by November 14. Forms of application together with the regulations governing the award of grants can be obtained from the General Secretary, The Chemical Society, Burlington House, Piccadilly, London, W.1.

The Institute of Welding has established a School of Welding Technology at its house at 54 Princes Gate, London, S.W.7, and courses on various aspects of welding, each lasting a week, will be arranged during October–March. Particulars can be obtained from the Secretary of the Institute.

The scientific activities of Morley College, London, are being increased in connexion with the rebuilding of the College, which was damaged during the Second World War. Still further facilities will be available when the new building opens early in 1958. The programme of courses on science, which include lectures on various aspects of natural history, gardening, public health, agriculture, photography, microscopy, astronomy and statistics, can be obtained from the Director of Science, Morley College, 61 Westminster Bridge Road, London, S.E.1.

The British Scientific Instrument Research Association has extended its forthcoming series of open days, originally to be held during the week October 7–11, to include October 14. Admission is by invitation only, and inquiries should be addressed to the Director, British Scientific Instrument Research Association, Southill, Elmstead Woods, Chislehurst, Kent.

The National Conference of the Institute of Personnel Management will be held in Harrogate during October 4–6. Further details may be obtained from the Secretary to the Institute at Management House, 80 Fetter Lane, London, E.C.4.

The sixth Anglo-American Aeronautical Conference, under the joint auspices of the Royal Aeronautical Society and the U.S. Institute of the Aeronautical Sciences, is to be held at Folkestone during September 9–12. The Conference is open only to members of the sponsoring organizations.

The Scottish Group of the Nutrition Society is holding a symposium on "The Nutrition of the Very Young" in Dundee on September 21. The papers to be read will deal with both infants and young farm animals. Further particulars can be obtained from Dr. J. Davidson, Rowett Research Institute, Bucksburn, Aberdeenshire.

ELECTRICAL ENGINEERING AT THE UNIVERSITY OF SHEFFIELD

NEW LABORATORIES

THE new laboratories of the Department of Electrical Engineering in the University of Sheffield were officially opened by Sir Harold Bishop (director of engineering, B.B.C.) on June 28. Speaking at the ceremony, Sir Harold referred to the problems facing the universities in their efforts to meet the growing needs of industry. "Whatever may be the answer to these problems," Sir Harold said, "the rate of expansion in the electrical industry (and I would remind you that the value of the exports of that industry are now greater than that of any other industry in this country) is clearly limited by the rate at which the supply of trained scientists and technologists can be increased." The new laboratories will, it is hoped, make a useful contribution by providing facilities for a substantial increase in the number of students of electrical engineering in the University of Sheffield.

The laboratories are accommodated in the applied science buildings facing St. George's Square. In addition to space previously occupied by the Electrical Engineering Department in these buildings, further space became available by the transfer of the Department of Civil Engineering, and most of the Department of Mechanical Engineering, into a new engineering building which was opened in 1955. In this way the floor area of the laboratories has been almost doubled, and the original laboratories, as well as the new laboratories, have been completely refurnished and re-equipped.

Four of the laboratories are used for heavy-current work, three mainly for machines, and the other for transformers, rectifiers and other static apparatus. One of the machines laboratories is the Edgar Allen Laboratory and is devoted to research in electrical machinery and related topics. A very comprehensive range of machines and other apparatus is available. A mono-rail and a small mobile gantry provide for the movement of heavy equipment. However, many of the smaller machine-sets are mounted on wheels, which gives great flexibility in use.

There are two large laboratories used mainly for undergraduate experiments in measurements, electric circuits and electronics. A small photometric laboratory with photometric bench, integrating-cube and other illumination test apparatus is available. In the standards laboratory a complete inner room has been built of aluminium-faced plywood to form a complete metal screen, with properly filtered incoming supplies. This is used for precision measurements, and is equipped with d.c. and a.c. potentiometers, bridges, and standards of resistance, inductance and capacitance.

The electronics laboratory and the microwave laboratory are used entirely for research. The former contains high-vacuum equipment generously given to the Department by the Metropolitan-Vickers Electrical Co., Ltd., while the latter is equipped with oscillators, wave-guide test-benches and other apparatus for experimental work in the microwave and decimetric frequency bands.

The Department also has two workshops, one of which is used by postgraduate students, and a battery-room housing a 200-V., 900 amp.-hr. centre-tapped lead–acid battery which supplies the 3-wire d.c. system throughout the Department. The charging equipment consists of a motor generator, a booster-balancer set and metal-rectifiers.

The electric power supplies in the laboratories have been designed to give the greatest possible flexibility consistent with reliability and safety. The light-current laboratories are generously provided with 3-pin, 13-amp. switch-sockets for both 240 V. single-phase a.c. and with 5-amp. and 15-amp. switch sockets for 200 V. d.c. These supplies meet most needs in these rooms, but each laboratory is also equipped with at least one four-wire, 30-amp. experimental terminal board, fed from a socket on the main switchgear cubicle in the large machines laboratory. This provides for interconnexion between laboratories and for special supplies if required. The 240-V. a.c. supply for these laboratories is taken from a 415-V., 3-phase and neutral, ring-main which has been installed for the general supply to the whole building. The direct current is supplied from the battery already mentioned.

In the four heavy-current laboratories a rather special system of distribution is used. The normal supplies available in these laboratories are: 415 V., 3-phase and neutral; 230 V., 3-phase and neutral; and 200 V., 3-wire d.c. (100/0/100), from the battery. With the exception of the Edgar Allen Research Laboratory, which has separate 415-V. and d.c. supplies, the main control for all the supplies to these laboratories is by isolaters and splitters located within the main cubicle in the large machines laboratory. Adjacent to this is the 415/230 V., 3-phase, 100-kVA. autotransformer, which also has 110-V. tappings taken to a socket on the cubicle.

The three supplies are not fed direct to the machines, except to a few of the largest, but are connected to a special cubicle in each laboratory. Each incoming supply to these is controlled by a fuse-switch, feeding a number of 4-pole sockets all separately fused. Four-core flexibles are used, with a shielded plug on each end, to connect these sockets to others which are connected to outlet or experimental points distributed around the laboratory. In addition, each cubicle has two sockets connected to corresponding sockets on the main cubicle in the large machines laboratory, where any inter-laboratory connexion can be made.

At the experimental terminal boards the four cables terminate in switch-fuses connected to insulated terminals (four colours). The terminal boards have doors with locks for access to fuses, and each is provided with an independent 13-amp. switch-socket for 240-V. a.c. supplies to oscilloscopes, portable lamps and other test apparatus. The connexions have been made systematically, so that not only is the phase-sequence correct at every set of terminals, but also the red terminal is always connected to the 'red' line, and when interconnexion is made between experimental points, the two sets of terminals are connected in the proper order. The cubicle in the large machines laboratory serves its own system within that laboratory as well as acting as the focal point to which all the others are connected. It has 60-amp. plugs and sockets, and so has the Edgar Allen Research Laboratory. The others have 30-amp. circuits. Wherever possible, the wiring is carried in surface trunking and is easy of access.

With the exception of the photometry and standards laboratories, which have tungsten filament lighting, the laboratories are very adequately lit by fluorescent lamps. These are switched in groups of three or six, fed from 3-phase a.c., with 3-pole switches, so eliminating stroboscopic effects and reducing the number of wall switches.

The University surveyor was responsible for the design and supervision of the alterations and additions, the electrical consultants being Hoare, Lea and Partners. The main buildings and fittings contractors were Geo. Longden and Son, Ltd., and the electrical contractors were the Yorkshire Electricity Board. The special experimental panels and cubicles were designed and manufactured by Field and Grant, Ltd. (Birmingham).

INTERNATIONAL TIN RESEARCH COUNCIL

TWENTY-FIFTH ANNIVERSARY

By Dr. ERNEST S. HEDGES
Director

To celebrate its twenty-fifth anniversary the International Tin Research Council invited visitors to the open days held at the Tin Research Institute, Greenford, Middlesex, on July 10 and 11. The Institute was built in 1938 to house the Council's headquarters and research laboratories, but after the War extensions were necessary and new laboratories were opened by H.R.H. the Duke of Gloucester in 1951. This had the effect of doubling the accommodation. The staff of the Institute comprises about twenty graduates and forty-five assistants, including maintenance and services. The present director has served the Council during the twenty-five years of its existence.

During the open days approximately six hundred people visited the Institute, among them many well-known scientists, technologists and industrialists. The full tour of the laboratories was designed to show the main developments which have resulted from the Institute's research work. The general scheme followed wherever practicable throughout the laboratories was to show the actual experimental equipment employed on investigations, pilot or full-scale plant for operating the technique developed from it, and commercially produced samples illustrating the final product.

An example of this treatment was to be seen in the Electroplating Department. Work having as its aim the production of electrodeposits of new tin alloys was initiated on a beaker scale in the first laboratory, developed on a 10-gallon scale in the second laboratory and brought to practical success on a 200-gallon scale in the third. Among the practical achievements of the Institute presented in this way was a considerable range of metallic coatings containing tin. The decorative and corrosion-resistant electroplate of tin–nickel alloy (66 per cent tin) was shown as a finish on an electric toaster, a table lamp, drawing instruments, spoons, chemical balance weights, slides of trombones and pistons of trumpets. Speculum (a tin–copper alloy containing 42 per cent tin) was seen upon a lamp, a fruit bowl and a reflector. Tin–zinc alloy (75 per cent tin) was shown on undercarriage parts of aircraft, radio chassis and motor-car accessories. This alloy coating has gained wide acceptance as a corrosion-resistant finish for steel. A recent development in this department which attracted much attention was the electrodeposition of 'bright' tin. This is a process for producing, without mechanical polishing, a pure tin coating having a mirror-like reflexion. Bright tin was demonstrated on a radio chassis stamped from unpolished steel sheet.

In a suite of laboratories specially designed for hot-tinning, the hot-dip tinning of steel and cast iron was demonstrated on such objects as frying pans. After tinning, these were immediately centrifuged in equipment designed at the Institute to remove excess of the still molten tin, leaving a bright and flawless surface. Tinned cast-iron meat mincers showed the great improvement in surface brightness and smoothness brought about by the use of new techniques worked out in this laboratory. Adjoining laboratories displayed equipment designed for the study of electrolytic tinplate produced under controlled conditions, including 'flow-brightening' by momentarily melting the surface. The many testing procedures which have emanated from this laboratory for assessing tin coatings quantitatively and qualitatively were also demonstrated.

The Metallurgical Department showed stages in the roller-welding of steel strip to aluminium–tin alloy strip so as to form composite strip, from which half cylindrical bearing shells for high-duty internal combustion engines can be formed by pressing and subsequent machining. This new type of bearing, which is now in commercial production, is already being used in tens of thousands of road vehicles. The continuous casting of bronze rod was a demonstration of much interest. The rod, produced at about 12 in. a minute, is remarkable for its high quality and accuracy to gauge diameter. The machine, which was expressly designed at the Institute to be of simple and inexpensive construction, has been adopted by many firms in Europe.

The Corrosion Department had exhibits to illustrate the advantages of each type of tin and tin-alloy coating under specific conditions of usage. The remarkable permanence of tin–nickel coatings under severe conditions, such as industrial atmospheres, impressed many visitors. The structure of surface films on tin and tin alloys is also a subject of study in this laboratory, using techniques by which the films are removed intact from the metal on which they form: several specimens of such films were on show.

Organo–tin compounds are among the most recent studies of the Institute and perhaps the one for which the brightest future seems to be in store. Certain of these compounds, containing a tin atom linked to three carbon atoms, are remarkably toxic to fungi. A practical demonstration was afforded by two timbers recently removed from a damp mine where they had been for more than three years: the untreated timber was crumbling away while the timber treated with a trialkyl–tin compound was unaffected and retained its full strength. Other exhibits showed the effectiveness of these compounds on timbers exposed to attack by *Teredo* and other marine organisms. Another type of organo–tin compound has exceptional ability to stabilize polyvinyl chloride plastics. Curiously, the same type of compound is used extensively in veterinary medicine as a worm cure and prophylactic for chickens and turkeys. The chemistry of organo–tin compounds is being rapidly extended by the Institute's research team.

Other departments shown included metallography, analytical chemistry, photographic studios, engineering workshop and a specialized library. Cinematograph films of processes devised in the laboratories were available for continuous showing to the visitors.

FULMER RESEARCH INSTITUTE

OPEN DAY

THE Fulmer Research Institute held an open day on July 2, to mark the tenth anniversary of the official opening by Sir Stafford Cripps on July 2, 1947. About 260 guests, representing industry, government departments and other research organizations, were present and were shown details of research work in progress.

The principal guest was Mr. R. Harmar Nicholls (Parliamentary Under-Secretary, Ministry of Works), who deputized for the Right Hon. Reginald Maudling. In a brief speech after lunch, Mr. Nicholls congratulated the Institute on its steady growth during the past ten years, and, in reflecting on the sources of the Institute's income, Mr. Nicholls was particularly gratified by the increasing number of dollar-earning research contracts, now constituting about one-third of the Institute's total income. He considered, however, that much greater use could be made by British industry of the facilities for research and development which are available at the Institute.

During the past ten years the Institute's effort has been principally devoted to some one hundred and fifteen major research programmes, and about thirty of these are in progress at the present time.

In the physical chemistry division of the Institute, headed by Dr. P. Gross, fundamental work on extraction processes relating to aluminium and titanium has continued. Pilot-plant work in industry on the catalytic distillation of aluminium has been in progress for some time and processes for titanium extraction which have been successfully demonstrated on the laboratory scale are now ready for extension to the next stage. A method of purification of silicon is now under experimental study and apparatus for the preparation of large single crystals of this element (by drawing from the melt) has been developed and is in use.

The work on extraction and purification processes is, of course, dependent upon accurate thermodynamic data, and specialized techniques have been used to study the equilibria of important industrial reactions and to establish activity data for various metallic systems. Accurate calorimetry has established the heats of formation of various compounds, in particular metallic halides, and new values for several of these important compounds have been published. Various reactions which might form the basis of new extractive methods have been studied in apparatus requiring highly efficient vacuum techniques. In the analytical laboratories, polarographic, absorptiometric, microchemical and spectrographic methods in addition to the more conventional techniques of analysis were demonstrated.

A study of the mechanism of precipitation hardening with particular reference to light alloys has always been a major item in the Institute's research programme. It was partly as a result of this work, much of which has been published, that Dr. H. K. Hardy, who has since joined the Atomic Energy Authority, gained the Beilby Award and Rosenhain Medal of the Institute of Metals. The X-ray techniques developed by the Institute's investigators for studying precipitation processes are well known internationally to specialists in the field. Trace elements have been shown to exercise a profound effect on ageing behaviour in some systems, and the influence of small quantities of cadmium, for example, on aluminium–copper alloys has resulted in the development of a series of alloys which, while free from room-temperature ageing after solution treatment, can be aged at elevated temperatures to yield properties approaching those of the duralumin type alloys. The effect of radiation on precipitation and ageing behaviour in aluminium alloys is now being studied, while in titanium and zirconium alloys attention is being paid to the crystallographic changes associated with the formation of the embrittling omega-phase. To assist this latter work and more particularly for studies on transformations in alloys of reactive metals, a special X-ray camera has been developed. It can operate with the specimen at temperatures up to 1,000° C. in a vacuum of 1×10^{-7} mm. of mercury.

Other X-ray studies have been concerned with the structure of liquid metals, and interesting results have been obtained with sodium and potassium (including binary alloys of these metals) and also gallium. The fundamental structure of glass is also being examined. Although in glasses the atoms are not arranged in a regular crystalline manner characteristic of metals, the arrangement is not completely random. On the slight degree of regularity which does obtain, an explanation of the variation of the properties of glass with heat treatment is sought. The problem is closely linked with that of liquid metals, and somewhat similar techniques of X-ray diffraction and refined interpretation are being applied.

A recent addition to the equipment of the physics section is the Metropolitan-Vickers electron microscope type ***EM3A***. This instrument, which has a resolution of 20 A. under favourable conditions and which can also be readily adapted for electron diffraction, is being used principally to study the mechanism of oxidation of low-alloy steels and to supplement the X-ray and metallographic investigations on age-hardening phenomena. A detailed investigation of the slip characteristics of certain metals is also in progress.

New equipment on view in the physical metallurgy section included a Reichert metallurgical microscope, a precision dilatometer for use in isothermal transformation studies and a high-temperature (up to 2,000° C.) vacuum heat treatment furnace. The last two items, together with much of the other equipment in use, were constructed in the laboratory workshops.

While considerable attention is still being paid to aluminium alloys, developments in the atomic energy field in particular have been reflected in the increased amount of work on the 'newer' metals, and uranium, titanium, zirconium, hafnium, niobium and vanadium all figure prominently in the current work of the Institute. A number of research programmes are concerned with the physical metallurgy of uranium and its alloys, and they include the determination of constitutional diagrams for certain binary alloys, the study of phase transformations, and determination of the crystal structure of uranium compounds. A metallographic study of the allotropic transformation in binary titanium zirconium alloys has recently been concluded.

In the work on materials for possible application at high temperatures, comprehensive investigations on binary and ternary chromium-based alloys have been followed more recently by an examination of the pure metal. Experimental and pilot-plant work on electrolytic processes has been concerned with identifying and controlling commonly occurring impurities and this has been coupled with an examination of the effects of these impurities on mechanical properties. Results of impact tests obtained on material which has been obtained by the lubricated extrusion of sheathed compacts have shown that this extrusion method has an effect of increasing the ductility and lowering the ductile/brittle transition temperature in chromium. A new retractable hearth argon-arc melting furnace for the production of chromium and chromium alloy ingots has recently been built.

Further attention has been paid to the low-alloy oxidation-resistant steels. A recently published report (Fulmer Research Institute: Special Report No. 2. "Oxidation Resistant Silicon–Aluminium Steels") describes fully the properties of these low-carbon steels containing silicon and aluminium developed at the Institute, which in air at temperatures up to about 950° C. exhibit a degree of scaling resistance comparable with the well-known austenitic stainless steels. Other work in the field of ferrous metallurgy has included an examination of the causes of failure of high-speed steels with special attention to the susceptibility of this complex material to overheating. Some short-term programmes have been concerned with nodular cast iron.

Long-term corrosion and stress corrosion tests are in progress on the various aluminium alloys, and particular attention has been paid to the effect of directionality of metallurgical structure on the initiation and rate of corrosion attack. Fundamental aspects of stress corrosion cracking and layer corrosion are under investigation and more recently a research programme to determine the effect of various metal coatings on the fatigue and corrosion fatigue properties of high-strength aluminium alloys has begun. The development of corrosion-resistant aluminium-base structural alloys, the development of oxidation and shock-resistant coatings for high-temperature materials, the assessment of a new material for domestic hot-water boilers, and an examination of coatings for the protection of high-strength aluminium alloys are other subjects under active investigation. The high-temperature corrosion of zirconium, a matter of importance for the application of that metal in nuclear reactors, is also the subject of a major research programme.

The primary interests of the engineering and mechanical testing laboratories lie in the fields of creep and fatigue. Fundamental programmes are concerned, for example, with assessing the importance of rest periods and cumulative damage on fatigue life. A specially designed high-temperature fatigue machine has proved particularly useful in studying the effect of various heat-resisting coatings on the high-temperature fatigue properties of the base metal. High temperature and corrosion fatigue studies are also being made using alternating tension and compression machines of the Haigh or 'slipping clutch' type.

Apart from the more usual tensile creep testing, small compression creep machines have proved particularly useful for the study of uranium and other highly reactive metals. A comprehensive investigation of the creep characteristics of certain binary alloy systems is also in progress to ascertain the effect on creep properties associated with changes in the solid state occurring at or near phase boundaries. Titanium alloys, aluminium alloys, magnesium alloys (for 'canning' uranium fuel elements), structural steels and cast iron are other materials on which creep-testing programmes have been carried out.

Facilities for mechanical testing have been adapted so that tests can be carried out at very low or high temperatures. Results have been obtained, for example, for sponsors interested in designing for low-temperature applications, such as the transport of liquid methane. The mechanical and thermal properties of various insulating materials have also been examined and another investigation has been concerned with the determination of the characteristics of oil filters by measurement of the pressure drop at various flow-rates of fluids of varying viscosities.

While much of the Institute's work remains confidential to the sponsors, more than one hundred papers and technical articles (in addition to a number of patents) have been published with the sponsors' permission. Reprints of most of these were available in the Institute's library, together with a large number of translations of foreign scientific papers, including many translated from the original Russian. A recently published booklet which was issued to visitors (and which is now available from the Institute) gives details of the organization and current activities of the laboratories.

COAL SCIENCE

THE Second International Conference on Coal Science was held during May 1–4 at Valkenburg, a holiday centre in Limburg, The Netherlands. In keeping with the atmosphere, meetings were held in a conference hall attached to one of the newer hotels, and members were entertained by the Burgomaster, F. A. A. H. Breekpot, at a reception in the Municipal Grotto. The purpose and background of the present biennial series of conferences have already been set out in *Nature* (176, 103; 1955).

The response to the requests for contributions showed that interest in the subject is still increasing. Ten countries were represented as compared with eight on the previous occasion, including the first from the Eastern bloc, namely, Poland, which sent four delegates headed by Prof. Roga, of Glowny Instytut Gornictwa, Katowice. Dr. M. Samec, director of the Kemični Inštitut "Borisa Kidriča", Ljubljana, attended as official delegate of the Slovene

Academy of Arts and Sciences. Coal scientists from Czechoslovakia had also intended to participate but were unable to obtain visas in time. The United States (both Government and industry) was directly represented for the first time. The great majority of conference members, however, were drawn from Germany, France, The Netherlands and Great Britain. Despite efforts on the score of efficiency to limit the numbers attending, the total was about 30 per cent higher than that at the previous conference.

On this occasion changes were made in the arrangements. Meetings took place in the morning and evening, leaving the afternoon free for informal contacts and excursions. All papers were concerned with experimental advances and none attempted to survey a whole field of research. Papers were photocopied in their language of origin, and sent to participants some weeks before the meeting; submission of written summaries of contributions to the discussion in advance was encouraged, so that some indication of the degree of interest in each paper was available to those planning the time-table. Authors were encouraged, on the whole with success, to present their papers in fifteen minutes on the assumption that they had been read in detail by those interested. These arrangements minimized the language difficulties which, however, were still noticeable when the time came for spontaneous discussion and authors' replies.

As on the previous occasion, members of the organizing committee took the chair in turn at the six sessions that followed the address of welcome by the president, Prof. D. W. van Krevelen. The subjects discussed were grouped under four headings: (*A*) chemical methods of coal research (chairman, E. H. Grand'ry); (*B*) new physical techniques in coal research (Dr. M. Th. Mackowsky); (*C*) physico-chemical studies of coal macerals (two sessions, Dr. I. G. C. Dryden and Prof. W. Fuchs); (*D*) fundamentals of coal carbonization (two sessions, R. Loison and Dr. D. C. Rhys-Jones).

The proceedings, including discussion, will be published in *Brennstoff-Chemie*, and in view of this it will be sufficient here to direct attention to selected points of novelty or special significance. A notable feature of the Conference was the increased proportion of work based on new approaches and departing from traditional lines of coal research. This healthy sign was the subject of comment, and it was felt by many that the Conference was one of the most satisfying of its kind in recent years.

A contribution by P. H. Given (British Coal Utilisation Research Association) was aimed at elucidating some of the factors controlling the reactions of coal with chemical reagents; he was able to show that the molecular-sieve properties of coals were of secondary importance in hindering reaction, and that where an expected change failed to take place, plausible chemical reasons could be suggested. Using some reagents, in particular bromine, the rate was as high with coal as with simple compounds thought to resemble it in structure. Perhaps the most significant of the results cited in a paper by J. J. Th. M. Geerards, D. W. van Krevelen and H. I. Waterman (Delft) was the production from cellulose in good yield of an oil resembling perhydrophenanthrene in analysis and infra-red absorption; an observation which suggests that the study of primary hydrogenation products may throw but little light on the constitution of an unknown material.

D. E. G. Austen and D. J. E. Ingram (Southampton) discussed recent work on the stable or trapped free radicals detected by electron resonance in coals and carbonized coals. These are few in number (about one to several thousand carbon atoms), and the proportion depends chiefly on the type of coal and temperature of carbonization. Their place in the chemical picture of coal and their influence on its properties are not yet clear. A paper by C. L. M. Bell, R. E. Richards and R. W. Yorke (Oxford) was also presented by Dr. Ingram. Interpretation of nuclear magnetic resonance measurements in terms of the linkages of hydrogen in coal is limited since the forms that can be distinguished are not grouped in the most convenient manner to answer key chemical questions, such as the ratio of aromatic to non-aromatic hydrogen. The preliminary results given did not agree closely with those deduced from comparisons of the intensities of infra-red bands, but in view of the uncertainties in both methods of deduction the discrepancy is more apparent than real. R. Westrik, of the Netherlands State Mines, contributed a study of coals by electron diffraction, which indicated in all samples an unexplained hexagonal spacing twice as large as that of graphite.

Historically there has been a tendency for the coal petrologist and the coal chemist to think on quite different lines and to work in separate compartments. In the papers of Session *C* substantial attempts were made to relate the two fields of inquiry more closely. The long-standing question of the relative merits of the use of polished surfaces and thin sections in the microscopic examination of coal was again discussed and some agreement was evident; it is clear that the methods are to some extent alternative, but also in some measure complementary to one another. Another noticeable tendency was the change in emphasis from discussion of the properties of rock types (the visible banded components of a coal seam) to those of the more fundamental macerals (microscopic components that may be compared with inorganic minerals). D. G. Murchison (Durham) described some well-planned experiments designed to settle a controversy that has long thwarted the effective use of reflectance measurements in the classification of coals: he concluded that variation of the reflectance of the basic microscopic constituents, vitrinites, as a function of their carbon content or rank, was probably not discontinuous.

Papers by A. Ladam, P. Iselin and B. Alpern (Centre d'Etudes et Recherches des Charbonnages de France), by C. Kröger (Technische Hochschule, Aachen), and by F. J. Huntjens, H. N. M. Dormans and D. W. van Krevelen (Netherlands State Mines) were all concerned with the properties, or the thermal decomposition products, of maceral concentrates. A measure of agreement is now apparent and one can indicate in semi-quantitative terms the relations between the chemical properties of a coal and the relative proportions of macerals in it. There are one or two surprising discrepancies between different investigators, but the difficulties are many: if separation is to be at all complete the coal has to be finely sub-divided, and it is then more difficult to express the microscopic analysis in terms of the normally recognized constituents because characteristic shapes and opacities have been modified. The authors of the last two papers mentioned have made especially comprehensive studies.

B. Lavrenčič (Kemični Inštitut "Borisa Kidriča," Ljubljana) gave an interesting account of the rheological properties developed when the unusual Yugoslav coals containing about 10 per cent of organic sulphur are heated; these coals have properties quite abnormal in comparison with classifications based on low-sulphur coals. D. W. van Krevelen, H. A. G. Chermin, H. N. M. Dormans and F. J. Huntjens described the dilatation of various blends of coals and coke on heating and its prediction from that of the components. Two papers, given by I. G. C. Dryden and K. S. Pankhurst (British Coal Utilisation Research Association), and by G. J. Pitt (National Coal Board), are usefully considered together, since the method of extracting, with chloroform, fusible material developed by coking coals on heating was common to both investigations, though in the second investigation scavenging by gas during the heating was considerable and in the first was eliminated as far as possible. A comparison of the two sets of results is of interest: for example, the rate of development of plasticity on heating at constant temperature (Pitt) is much smaller than that of the development of chloroform-soluble material by thermal decomposition. This indicates that the chloroform extract, though known to be associated with the development of plasticity, is by no means the only factor involved.

E. A. Depp and M. B. Neuworth (Pittsburgh Consolidation Coal Co.) discussed the pyrolysis of model compounds thought to embody the type of chemical structure that exists in coals. Interesting results were obtained, but the work is laborious and more variants of structure are needed before drawing firm conclusions; moreover, the existence of a few specially weak linkages in coal may determine the temperature and course of decomposition and to some extent invalidate comparisons with simple pure compounds (compare the different behaviour of synthetic polymers from that of their monomers). Prof. M. Letort (Nancy) presented a most interesting paper on a new type of adsorption isotherm (methane on graphite) which appears to show discontinuities corresponding to completion of successive molecular layers of adsorbate. Prof. Letort suggested that the necessary condition was a special correspondence between atomic spacings in the adsorbent and adsorbate, and that the method could be used to follow the development of graphitization in carbonaceous solids when heated.

Finally, those attending were privileged to see a remarkable colour film made by W. Spackman, W. F. Berry and A. H. Brisse in the United States which showed the behaviour of certain coal constituents on heating thin sections under the microscope. This was not only fascinating to watch but enlightening as to the different interactions between constituents that must occur prior to the formation of coke.

There was some private discussion as to the future value of conferences on coal science in view of the impact of atomic energy. There seems, however, little doubt that the use of coal will be maintained for several decades to come—in the United States it is expected to increase considerably—and that the emphasis will shift from combustion towards chemical conversion. The success and liveliness of this conference encouraged the view that further meetings were desirable at least in the immediate future. It is generally agreed that nowadays conferences proliferate too freely, and it is certainly necessary to examine carefully the reasons even for maintaining an existing series. There is room for much experiment in methods of organizing, particularly in order to reduce the work involved for both organizers and participants, and the amount of irrelevant and repetitive material that has sometimes to be read before the real points for discussion become apparent. This meeting was partly successful in these respects; it is hoped that further improvements can be made on the next occasion. I. G. C. Dryden

MUSEUMS ASSOCIATION

ANNUAL CONFERENCE

The sixty-third annual Conference of the Museums Association was held in Bristol during July 8–12 under the presidency of Sir Philip Hendy, director of the National Gallery. Nearly four hundred delegates attended, and the Conference opened with a conducted tour of historic Bristol and an informal reception at the University, where members were received by the vice-chancellor, Sir Philip Morris. The official welcome by Alderman Percy W. Raymond (Lord Mayor of Bristol) was followed by a vigorous address from Sir Philip Hendy, who dealt with various activities within the museum movement during the past year. He referred to the successful outcome of the negotiations between the Durham County Council and the trustees of the Bowes Museum at Barnard Castle, and also to the slow progress of talks with the government officials regarding State aid to museums. The plight of some of the smaller museums was described as desperate, and although Sir Philip felt that the nation as a whole was far more museum-conscious than ever before, there was a lack of sympathy in Treasury circles. He felt that there should be a far more equitable distribution of cultural benefits among the organizations and institutions concerned.

The same theme was followed in an afternoon session under the chairmanship of Sir Mortimer Wheeler, who said that in spite of the Treasury's declaration to the contrary, the problem was not purely local, but a part of a general national educational problem. He recalled the scheme in Wales for mutual aid and affiliation between the National Museum of Wales and the museums of the Principality, and considered that it might serve as a model for other regions. Dr. Dilwyn John then outlined the Welsh scheme to which nineteen museums now belong, and Mr. S. D. Cleveland suggested a pilot survey in one part of Britain which might lead the way to a more general plan. Sir George Dyson, chairman of the Carnegie United Kingdom Trust, said that the first step must be to obtain common agreement between the various public and private authorities concerned. Mr. Philip James directed attention to the plight of many museums and art galleries owned by private trusts or societies, and emphasized the importance of ventilating these matters in the Press. Other speakers stressed the urgency of the situation, and in summing-up Sir Mortimer Wheeler said that he felt that a survey carried out in a relatively restricted area, such as south-west England, would yield information of value. Based on that experience, it would be possible to extend the survey to the whole country. As suggested by Mr. W. J. Deacon, it might be possible for regional museum boards to be formed and to base their constitution on the regional advisory boards of the Ministry of Education.

During the Conference the whole of one day was devoted to museums in the Commonwealth, this being an especially appropriate subject to discuss in the seaport of Bristol. It was a particularly interesting session, and the problems of struggling institutions in distant lands was considered under two headings: first, building, administration and finance; and secondly, training of staff. Speakers from Canada, India, Sarawak and various parts of Africa contributed to a stimulating discussion, and for comparative purposes there was a paper from Miss Toby Rose, of New York. In the majority of cases finance was not the major difficulty and most speakers agreed on the greater difficulties encountered in the training of staff. Dr. D. B. Harden, chairman at this session, announced that both South Africa and Canada had initiated training schemes for the diploma of the Museums Association. It was suggested that the Museums Association should appoint an honorary overseas officer who would have the services of a salaried official. It was considered important that a public demand for museums should be created and that they should be aware of these institutions.

Another session was devoted to scientific and technical problems under the chairmanship of Dr. H. J. Plenderleith. Dr. W. E. Swinton described the progress in these matters that he had recently seen in the United States. Dr. A. E. A. Werner, of the British Museum Research Laboratory, who followed, dealt with the subject of heating and ventilation. He first discussed the cardinal principles which must be observed if damage due to unfavourable environmental conditions is to be avoided, and pointed out that it was necessary not only to maintain the atmospheric relative humidity within reasonable limits—the minimum being 45 per cent and the maximum 65 per cent—but also to prevent rapid changes in humidity, particularly in art galleries where panel paintings are exhibited, as well as to ensure continuous and adequate air circulation around the museum objects. The practical problems involved in the control of relative humidity, air circulation and also air cleaning to remove harmful atmospheric pollution were outlined, and this was followed by a brief description of the various types of standard self-contained units that are commercially available for complete or partial air-conditioning. Emergency methods that can be used in stores and repositories, involving the use of simple apparatus such as electrically heated tea-urns and fans, were described. The importance of having some means for continuous recording of relative humidity (and of temperature also) was emphasized, and attention was directed to the precautionary measure of using a sling psychrometer to detect air pockets in which a high relative humidity may build up and encourage both mould growth and metallic corrosion.

Mr. W. E. Rawson-Bottom (Ministry of Works), after a brief review of the evolution of museum lighting from the days of the 'fish-tail' gas burner, stated that at the present time developments were proceeding rapidly chiefly because it is recognized as an essential aid to display. Museum lighting is a problem for the co-operation of the lighting engineer, architect, display designer and curator, and it is essential that attention should be directed to the exhibits rather than to bare lamps or fittings of high brightness. In other words, lighting should produce an effect without an apparent cause. One method is to use a type of louvre fitting. In case lighting, not only are the position and colour of lamps important, but also the selection of background colour.

Mr. B. S. Cooper (Research Laboratories, General Electric Co.) directed attention to some recent work on the fading and tendering of dyed fabrics, and pointed out that the humidity requirements most suitable for minimizing fading might well be far from the optimum in respect of loss of strength of the fabric. He also pointed out that, in considering possible photochemical hazards to exhibited material, the level of illumination was usually a far more important factor than the spectral character of the light used.

At the annual general meeting Sir Philip Hendy was re-elected president for 1957–58; it was decided to hold the next annual meeting in July 1958 in London and to invite Museum Dag from The Netherlands to take part. Honorary fellowship of the Association was bestowed upon Dr. Paul Coremans, of the Central Laboratory of Belgian Museums, Brussels, and others, including Dr. H. C. Blote, of Leyden, Holland, were elected to fellowships.

F. S. WALLIS

LARGE TELESCOPES

DR. R. v. d. R. WOOLLEY, the Astronomer Royal, delivered the James Forest Lecture to the Institution of Civil Engineers on May 14 on the subject of "Large Telescopes". Dr. Woolley dealt with the different kinds of telescope and their mountings and with the construction of domes and the methods for rotating them. He then explained the serious difficulties—and the methods adopted for circumventing them—encountered in large telescopes, owing to flexure in the glass of the mirror, and also flexure in the tube itself. When all these troubles have been overcome, there are still serious limitations even with the largest telescopes, some examples of which were given. For first-class stellar spectra the 200-in. telescope at Mount Palomar will only go to magnitude 8 and to magnitude 12 for reliable radial velocities.

Some years ago a number of British astronomers launched a project for building a 100-in. telescope, and obtained Government approval in principle for financing the scheme. This Isaac Newton telescope will be situated at Herstmonceux and will, it is hoped, be completed by 1962. The sky at Herstmonceux is, as England goes, remarkably good, and as Dr. Woolley says, "It is hoped that the Isaac Newton telescope will do much to promote a vigorous resurgence in the practical as well as in the theoretical problems of astronomy in this country". Informing his audience that science and scientific techniques are closely interlocked, and that even if astronomers fail to convince the public that large amounts of their money should be devoted to the disinterested survey of the heavens, he proceeded: "We may remind them that in this technical age, survival as a first-class nation can only be secured by a thorough realization of the fundamental importance of science and technique. As an integral part of this, we may urge the importance of astrophysics: and as an essential tool of astrophysicists, astronomers feel justified in calling for public support for large telescopes".

CO-ORDINATED RESPONSE TO STIMULI IN CORAL POLYPS

WITH the assistance of an award from the Commissioners for the 1851 Exhibition and of a grant from the Royal Society, Dr. G. A. Horridge left the cold waters of the North Sea for a period of two months to visit Ghardaqa on the Red Sea, in order to study the response to contact stimuli of corals living in that warm sea. A report of this work has recently been published[*]. The term coral includes so many subclasses, orders and families that no conclusions regarding response can be formulated which will apply to all of them. Most corals expand only in darkness and do not keep well under artificial conditions, so that Dr. Horridge worked chiefly at night, with a dim light, and used fresh material for each experiment. Electrical stimulation was based on the discharge of a condenser as described by Pantin, and the number of polyps which began to retract was recorded visually. The progressive spread of excitation across the colony in response to successive shocks at short regular intervals was observed. To take two examples: in a gorgonid (*Acabaria pulchra*) a stimulated tentacle reacted, and the retractions gradually spread to neighbouring tentacles, until all the tentacles of one polyp had contracted symmetrically, but unlike other corals there was little co-ordination between the polyps of the colony. In *Tubipora*, on the other hand, there is a highly correlated conducting system, although this is subject to the intensity and repetition of the stimulus. In more than a dozen species studied, however, it was found that the individual polyps possess a conducting system which co-ordinates their retraction through the mesenteric muscles. At first the reaction is slow, requiring a second shock to activate it fully, and causing a jerky wave of polyp retraction, differing from the slower and more continuous feeding response.

A working model was constructed to illustrate the effect of conducting and non-conducting units in inter-neural facilitation in a two-dimensional net, using a perforated board with movable pegs. The non-conducting unit is assumed to be so "at the instant when an impulse arrives", but the connexion "becomes conducting for later impulses which may arrive within a specified time". Experiments with the model, however, do not coincide with those on the living colony in certain species, the spread of excitation in which is less than that in the model. To account for this variability a second model was used. The nerve net is now considered as a population of cells, and an impulse excites only a proportion of the cells in a group. In some species, and in others after low stimulation, there was no interaction between units; in other species the wave of excitation spreads when more than a critical number of units is stimulated.

The inter-neural facilitation theory of Pantin assumes an all-or-nothing response, in which a series of separate units forms, for the time being, a continuous pathway. This theory is inadequate for the corals, and requires modification along the lines suggested by Dr. Horridge. Yet all theories await histological research on the nerve net of corals.

THE EUROPEAN BADGER

SOME interesting observations on tame and wild badgers (*Meles meles meles* (L.)) have been made by John Sankey, of the Juniper Hall Field Centre at Dorking (*South-Eastern Naturalist and Antiquary*, 60, 20; 1955).

The tame badgers were kept in captivity primarily to obtain information on their breeding cycle and habits. This has not yet been possible, but other information, otherwise difficult or impossible to get by watching the animals in their natural habitats, is recorded in the paper.

All the animals were obtained within six to about eight weeks from birth. At about two months the cubs emerge from the sett for the first time, and older badgers have usually been so conditioned to their natural life that it is impossible to tame them. Young animals taken before or at this critical point of development will readily take to a human, and, by frequent handling and attention, become very tame. Their reactions to certain situations are often remarkable and amusing. Badgers vary in their temperament, the females probably being more equable.

The badgers thrived on a variety of foods, and the diet could be varied within wide limits.

From observations on eight females and seven males the average weight of a badger about eight weeks old was found to be 4½–5 lb. The difference in weight between the sexes does not appear to be significant at this stage, and any deviations from the normal might be due to other heredity or nutritional causes.

From specimens reared, but not born, in captivity the weights of the adult male and female differ more. The male is, on an average, a little more than four pounds heavier than the female. These badgers appeared to be fully grown, but not necessarily sexually mature, about the autumn of their first season. Little increase in weight occurred from then onwards.

Badgers lose some of the smaller white hairs during the first summer, and the longer, thicker hairs are gradually replaced. A noticeable moult occurred from the beginning of June and lasted for several weeks. This appears to be the badger's annual moult. Scratching is intense during this period, and the hair may be shed in quantity.

Several of the captive animals died when young, mostly before eight weeks. Since their former life is unknown, that is, at the time when they were dug out or where caught in some other way, little can be deduced about their resistance to disease, though two cubs succumbed to a pneumonic infection which they had contracted previously.

There is little information about whether badgers do bathe in pools, ponds and rivers. Observers agree that badgers drink water, and this was confirmed by the captive badgers. Bathing is recorded in the case of three males and three females, but only during summer. One female began to go into water at about five months, and all the others bathed during their first summer. When the weather is warm, a bath is taken regularly. It seems very probable that wild badgers go into water regularly in the summer months. Badgers keep their faces very clean. The action is similar to that of a cat; the paw is licked and wiped over the face.

All the badgers reared beyond eight weeks have retained the natural habit of "setting scent" in captivity. Scent may be frequently set on the same object, such as a man's shoe. Unfamiliar objects interest the badger; but the fact that scent is set on familiar things, on which it was set perhaps only a few moments before, is difficult to explain.

The scent appears to serve the purpose of marking out territory and to enable the creature to locate its whereabouts. There appears to be no difference in this habit between male and female even when kept together. Nor is there any modification in the setting of scent in the presence of dogs and tame foxes. Fear causes the sudden release of musk in tame badgers. The fluid is milky-yellow and of moderately thick consistency.

Only four sounds have been noted in the case of tame badgers. First, there was a persistent rhythmical whimpering in young specimens which was nearly always followed by death; this was apparently a note of discomfort or pain. Secondly, there was a low continuous guttural purr produced when food was smelt, or when the animals wanted attention; this was probably a conditioned feeding request. Thirdly, a deep-throated muffled growl, which was clearly a note of warning, and sometimes followed by attempted attack. Fourthly, there were puppy-like yelps used only during play, and more especially in juveniles up to about six months.

The badgers were reared and kept on an artificial diet. Small quantities of vitamins and salt were added to the food from time to time. The food taken confirms the badger's omnivorous nature. Meat is undoubtedly preferred, and sweet things are greatly liked. One female badger drank small quantities of mild ale, and a male on several occasions lapped sweet wine. A number of natural foods were tested—among them being earthworms, insects (some showing aposematic colours) and molluscs. Most of these (including some insects with aposematic colours) were eaten, with the exception of the Roman snail (*Helix pomatia* L.).

In his observations on wild badgers Sankey showed that badgers can become conditioned to the presence of man; little attention need be paid to whether the badgers smell the observers.

Badgers pick up food anywhere, but usually have fairly well-defined feeding grounds; there is a definite pattern of tracks from the colonies to the feeding grounds. Dung pits are concentrated near the setts or the feeding grounds, and are seldom seen elsewhere. Yew berries appear to be eaten fairly liberally in the autumn but are often regurgitated.

The loud "blood-curdling" noise described by Neal has been recorded, and supports Neal's opinion that this call has no sexual significance; it does not preclude the possibility that on occasion it can be used to attract from a distance an animal of the opposite sex. The observations also suggest that the sound has nothing to do with the dismissal of the cubs.

The article also contains an account of an old badger-baiting pit.

AN ELEMENTARY THEORY OF INTERSPECIFIC COMPETITION

By M. H. WILLIAMSON

Department of Zoology, University Museum, Oxford

THE proposition known as Gause's hypothesis is often stated so as to imply that two species cannot remain in competition indefinitely. In the mathematical theory of competition cases occur in which two competing species can coexist. The word 'niche' has been used in discussions on this subject, but not in such a way that it can be applied unambiguously to field data. It would therefore seem worthwhile to restate and develop the mathematical theory so that its relation to particular situations in the field is more readily apparent. Before this can be done, it is necessary to discuss what is meant by the word competition. There are almost as many definitions of competition as there are authors who have written on the subject, and it would be pointless to mention all the variants that have been proposed. Instead, an argument will be developed which leads to a definition that can be treated mathematically, and comments on other definitions will be given during the argument.

The usual meaning of a word must be considered when defining it for scientific use. No doubt Andrewartha and Birch[1] had some such idea in mind when they said that "The literal meaning of 'compete' is 'together seek' ". This is not the literal meaning of compete but a literal translation of the Latin *competere*, which means to coincide. The Concise Oxford Dictionary gives 'strive with another' as a possible meaning of compete, and this suggests that there are three properties that must be included in a definition for use in ecology. These are: (1) that competition is mutual or reciprocal; (2) that it is harmful; (3) that the action of A on B is of the same type as the action of B on A.

Properties 1 and 2 are equivalent to the definition given by Odum[2], when he says that the effect of population growth and survival of species A on species B is negative and the effect of B on A is also negative when they are in competition. Elton and Miller[3], by saying "*Interspecific competition*, in the more limited and correct use of the notion, refers to the situations in which one species affects the population of another by a process of *interference*, i.e., by reducing the reproductive efficiency or increasing the mortality of its competitor. Or both species may be acting in such a way on each other", deliberately exclude property 1; but it is difficult to distinguish between some cases that they would call competition and, say, predation. The bearing of (3) on ecology can perhaps be clarified by an imaginary example. Suppose that a population of predators, say, dogs, are feeding on a population of prey, say, rabbits. Suppose also that many of the dogs are poisoned by eating the rabbits. Then the effect of the dogs on the rabbit population and the effect of the rabbits on the dog population would both be negative, and so by Odum's definition the species are in competition, although the situation is not one which most people would consider to be competition at all.

At this point it is necessary to define the term 'controlling factor'. By this is meant a factor which acts more severely against the individuals of a population when the population increases, and which has an appreciable effect, and so tends to control the population size. This is often known as a density-dependent factor; it is called a "concurrent density-dependent factor" by Solomon[4] and a "negative density-dependent factor" by Haldane[5], but factors could exist with the right density relationships but which nevertheless would never act at densities reached by the population in practice. The theory of the control of populations by controlling factors has been understood for a long time; it was, for example, stated clearly by Wallace[6], and a simple statement of the case is given by Moran[7]. Andrewartha and Birch[1] seem to think that controlling factors are unnecessary because environments vary. In fact this variation makes them more important, in the same way that a car needs more steering on a rough road than on a smooth one. In a deterministic system a species with birth- and death-rates equal to one another persists indefinitely, while in a stochastic system it inevitably becomes extinct[8], if it is not controlled.

Crombie[9] and others have realized that inter-specific competition involves controlling factors, as increases in density will intensify the mutual harmful effects. Competition between two species *A* and *B* could then imply either that both have a controlling factor in common or that *A* acts as a controlling factor for *B* and vice versa. The second possibility would almost certainly involve each species acting as its own controlling factor as well, and so reduces to a special case of the first. One can say then that two species are in competition when they have a controlling factor in common, and conversely, if two species are in competition they have a controlling factor in common.

This definition is precise and yet broad. It includes the competition in which each species attacks the other, it includes competition for food or sites, and it also includes competition to avoid an enemy, to avoid a predator, a parasite or a disease, that is, cases in which two victim species are in competition because they are both controlled by the same enemy. The observable results of all these types of competition will be much the same, and it is inconvenient to be able to identify a process and yet not give it a name. Those who would like a narrower definition must invent some term to cover competition as defined here, while it is easy enough to restrict discussion to certain classes and still keep the broad definition by talking about, for example, competition for food.
